faster than the rest of the filament, and in this way the diameter throughout becomes perfectly even in a few moments.

The size lamp generally used gives 16-candle power and from 10 to 15 of these can be lighted per horse-power. Lamps are made of different efficiencies, the most usual consumption of power being from 3 to 4 watts per candle-power. Incandescent lamps are connected in multiple, that is, each lamp is connected across the two conductors leading from the poles of the generator. In special cases large lamps of high candle-power are connected in series on arc light circuits, and miniature lamps of small candle-power are used several in series on incandescent light circuits. The usual voltage of incandescent lamps is about 100 volts, although some 50-volt and a few 200-volt lamps are in use.

ELECTRIC LOOM. See WEAVING.

ELECTRIC MOTORS, machines for converting electricity into mechanical power, in construction and principle identical with dynamos (see MAGNETO-ELECTRIC MACHINES), and differing only in a few minor points. They are fitted with one or two appliances usually, for stopping and starting them and regulating their speed and power. Being in fact dynamos, they have the same efficiency of about 90 per cent.; that is to say, a motor which is supplied with 100-horse power of electricity will furnish about 90-horse power to the machinery it is driving. The special advantages are that they are small, light, clean, easy to manage, and can receive any amount of power through a small wire led into the building at some convenient out-of-the-way place. Owing to these advantages, power can be obtained and used in many places where it would be out of the question without the aid of electricity. Street cars may be propelled by it, the shafting on the different floors of factories may be driven without connecting belts passing through the floors, and power may be obtained in places where the amount needed is so small that the expense of a steam-engine and attendant would be out of proportion and too great. Among the machines frequently requiring power in such places may be mentioned small elevators, ventilating fans, sewing-machines, and all kinds of machinery. Current for driving motors is obtained either from galvanic batteries, in the case of very small machines, or from the dynamo circuits from which electric lights are supplied. A vast number of motors are supplied with current from lighting stations during the daytime when but little demand for lighting exists. There are two general methods of supplying the electric current for operating motors, known respectively as the *multiple arc* system, which is the same as that by which incandescent lights are supplied, and the *series* system, by which arc lights are supplied. See ELECTRIC LIGHTING.

In the multiple arc system the electricity is kept at constant pressure, while the quantity which passes into any machine connected to it depends upon the size of the passage which is offered to the electricity, in the same way that the amount of water which will flow out of a tank depends upon how wide the valve is opened. Motors connected to such circuits regulate themselves by cutting off the current when the speed of the motor has reached the proper limit.

Among motors of this kind are the Edison, Thomson-Houston, C. & C., and others. In the series system a definite amount of current is forced through the wire, and the amount of electric power absorbed is regulated by forcing this definite current to do more or less work as it passes through. Motors operating on such circuits cannot regulate themselves by cutting off the current when sufficient speed is attained. In place of this, a number of devices have been made for the purpose of regulating motors on these circuits. One arrangement for this purpose is that employed in the Crocker-Wheeler motor. It consists of a gramme ring armature revolving in a stationary field magnet and provided with a governor attached to the shaft within the pulley of the machine. When the speed of the motor reaches the proper limit, the governor draws the armature lengthwise out of the field, thereby weakening the power, and keeping the machine running at constant speed under any variation of the work required of the motor. See the *Electric Motor and its Applications*, Martin and Wetzler; *Dynamo-Electric Machines*, S. P. Thompson.

ELECTRIC ORGAN. Electricity is used in two ways in operating organs—for pumping and for operating the valves leading to the various sounding tubes in accordance with the manipulations of the key-board. In many places, especially in large churches having complicated organs, a part of the organ tubes are at such distance from the key-board as to preclude the air being admitted to them and shut off quickly as is required in playing, by any mechanical means which can be actuated by the weak force with which the organist depresses the keys. To meet this difficulty, the agency of electricity has been invoked, and now in all large organs the connection from tubes to key-board is made in this way: The valve admitting the air to the sounding tube is controlled by an electro-magnet. This magnet is connected by a wire to the key-board, and is led to a contact point on the under side of the key corresponding to this tube. The wire is also connected to a suitable battery which supplies the current when this key is depressed, and also supplies the wires leading from all the other keys to the other tubes. When the keys are depressed by the organist the magnets throw open the air valves, and the corresponding notes are sounded without effort of the operator. The application for pumping air for organs is made by the use of an ordinary electric motor (q.v.), the motor being connected to an electric light circuit to draw its supply of electricity and geared to the bellows of the organ, so as to operate the latter.

ELECTRIC RAILWAYS. The most extensive application of the transmission of energy by electricity is its use for operating electric railways. In all such roads the power for propelling the cars is supplied by a steam engine or other prime mover at a central station, and is converted by a dynamo into electric energy, which is carried by suitable conductors parallel to the car tracks. By means of sliding contacts this current is led to an electric motor upon the car, which converts the electric energy back to mechanical energy for propelling the car. The invention of the electric railway is generally credited to Thomas Davenport, a self-taught blacksmith, of Vermont, who constructed several models of electric railways in 1835, some of which are still in existence. Numerous experiments in electric propulsion followed the attempts of Davenport, but no practical commercial system was devised until 1888, just fifty-three years after the original invention. From 1880 to 1888 a number of experimental roads were constructed, but the first successful electric railway in its modern form was opened in Richmond, Va., Feb. 1, 1888. The full-page illustration shows the central station of this road.

On January 1, 1895, the number of electric railways in the United States and Canada was as follows:

| STATE. | No. of Roads. | No. of Miles of Track. | No. of Motor Cars. |
|---------------------------|---------------|------------------------|--------------------|
| Alabama..... | 6 | 66.75 | 79 |
| Arizona..... | 1 | 5.00 | 4 |
| Arkansas..... | 5 | 44.00 | 54 |

| Total..... | 677 | 10,013.77 | 16,927 |

The total number of surface railways in the United States driven by animal power, electricity, and cables is about 950.

The three principal parts of an electric railway are: (1) the central station; (2) the line and track construction; and (3) the car equipment.

Central Station.—The power plant which operates an electric railway is preferably situated as near as possible to the centre of the system of car lines to which it supplies power, and contains a power plant, by means of which the dynamos are driven. The dynamos for railway work, as well as the engines, are very substantially built, owing to the heavy and constant changes in the load, caused by the stopping and starting of cars. In starting the motor car of the average size used on street railways on a level road about twelve to fifteen horse-power is required at the station, which amount, however, may be considerably increased by a bad condition of the track. In starting up steep grades three or four times as much power may be needed, but this excessive load is only momentary, and the power expended falls rapidly to half or less of that used in

Central Station for supplying Electricity.

starting as the car gains momentum. This condition of sudden and wide fluctuations in the load imposes the need of very sensitive and quick-acting engine governors, as the dynamo speed must be kept constant.

Line and Track Construction.—The single overhead trolley system has, with a very few exceptions, been generally adopted in the U. S. and Canada. In this system the current is led from one pole of the dynamo to a single wire suspended over the centre of the track, and reaches the car motors through the trolley-wheel and arm, whose upward pressure keeps it constantly in contact with the overhead wire. From the motor the circuit is completed to the other pole of the dynamo through the car-wheels and the track, which acts in the same capacity as the overhead conductor. Trolley lines are constructed with either hard drawn copper or silicon bronze wire of from a quarter to half an inch in diameter, and are supplemented by parallel feeder wires, with which they are connected at regular intervals. By dividing the overhead lines into two or more parallel strands it permits the trolley wire to be divided into sections or blocks, any of which can be disconnected from the system and repaired in case of accident without affecting any other sections of the road. The trolley wire is insulated by the hangers which support it, the bodies of which are composed of various insulating materials, such as moulded mica, porcelain, etc. The tracks, which are used as conductors, are connected so as to form a continuous metallic circuit from the car-wheels to the dynamos at the station, and as the rail-joints cannot be relied upon to make a good electrical connection, on account of the non-conducting rust which forms on the surfaces in contact, it is necessary to either bond or weld the tracks. Bonding is the general practice, and consists of riveting a wire at the ends of two rails, so as to form a by-path around the joint. The two parallel tracks are also cross-connected by bonds at intervals of the length of a rail. The tracks thus connected are supplemented by ground wires corresponding to the feeders for the trolley wire. Since the introduction of electric welding several attempts have been made to weld the ends of the rails together, making a single unjointed rail of the entire length of the road. This method has been only partially successful, as there is a tendency to breaking at the welds, due to the expansion and contraction of the track at different seasons. The best results with welding have been obtained with deep rails, in which the greater surface is under ground.

Several other methods have been employed for distributing the current to the cars, but none of them have attained much prominence. The double overhead trolley system, in which the second wire corresponds to the track circuit, described above, is still in use on a very few roads, but is undesirable on account of the crossing of wires of opposite polarities at switches, track-crossings, etc., and the liability of short circuits from falling telephone and telegraph wires. A number of conduit systems have also been devised, all of which may be divided into two classes—open or slotted conduits and closed conduits. In all conduit systems the chief obstacles lie in the expense of construction and the difficulty of securing proper drainage. Either one trolley wire and a track return or two trolley wires may be used with the open conduits. A successful example of the latter construction is the street-car system of over twenty-five miles in Budapest, which has been in operation for several years. Closed conduit systems are those in which, by electromagnetic switches or other automatic devices, the current is supplied only to the section of the conductor directly beneath the car. One arrangement of this kind, which will illustrate the object in view, was to place a bare conductor in a rubber tube, similar to a hose pipe, upon the upper side of which was placed a line of contact points, fixed like rivets through the tube. As the trolley traveled along the tube, which was flattened by its weight, these contacts were pressed down upon the inclosed bare conductor, and the current was thus led to the motors. The tube springing back to its normal shape only delivered current at the point where it was pressed down by the trolley. A great deal of attention is being given to the subject of closed conduits.

Car Equipment.—One or more electric motors geared to the car axles and a controlling switch on each platform constitute the principal parts of a motor-car equipment. Instead of having the journal boxes attached to the car frame, as in horse cars, the motors and running gear are attached to a car truck, on which the car body rests. The remarkable improvement which has been made in the design of street-car motors within the last four or five years is the principal cause of the success of electric railways. The first car motors were entirely too light mechanically and of too small capacity. From a single fifteen horse-power motor driving one car axle, the capacity of the car equipments has been gradually increased up to the present practice of using two twenty horse-power motors, one geared to either axle. A marked improvement has also been made in the reduction of armature speeds, so that the use of a double reduction in speed by means of a countershaft and two pairs of gears between the armature shaft and the car axle is almost obsolete. Gearless motors, in which the armature is built on the car axle, have been introduced by one manufacturer, but single-reduction motors having the armature shaft geared directly to the car axle are most commonly used at present. Almost all modern car motors are of the multi-polar type instead of the bi-polar, as formerly, and the reduction in armature speeds is due to this change of design. The severe service to which street-car motors are subject has led to making them very substantial in design, in order to avoid mechanical injury, and so-called ironclad (can refer to illustration under *magneto-electric machines* of Westinghouse Ironclad Car Motor)

motors, in which the field magnets form a closed iron box, are largely used to prevent short-circuiting by water or by nails or scraps of iron picked up by the magnets. Most of the single-reduction, four-pole motors are supported on one side on the car axles by journals set in projecting lugs at each end of the motor frame, the armature shafts being parallel to the car axles. The opposite sides of the motors are connected to the frame of the car truck by means of springs, and a pinion on each armature shaft meshes with a gear wheel on either axle. The function of the springs is to avoid a shock on starting the car, by permitting the motors to turn through a small arc about the axles. In gearless motors the armature shaft is a hollow tube, through which the car axle passes, and to which it is flexibly connected by means of springs. Another method in use with some geared motors is to place the motor on the truck with its shaft at right angles to the car axles. The shaft carries a bevel pinion at each end which mesh with bevel gears on both of the car axles. With this system a single motor of large capacity is used. A number of attempts have been made from time to time to connect the armature shaft and the axle by belts, sprocket chains, friction clutches, etc., none of which has been able to stand the service.

The starting and regulation of speed of the car is effected by means of the controlling switches on the car platforms. The methods of regulation of the different electric railway systems are too numerous to be described in detail, but the same general plan is common to them all. Series machines are always used in railway work, and the field windings are wound in a number of separate sections, the ends of which are carried to contact pieces in the controlling switches. In addition to the resistance of the field winding a resistance box is also used. The contact pieces in the controller press against corresponding rows of metal plates, each row having its plates connected so as to vary the connections of the wires from the motor. In starting the car, the resistance box, sections of the field coils and armature are all in series to prevent a too large passage of current through the armature. The next turn of the switch cuts out more or less of the resistance box circuit, allowing more current to pass, and by successive movements of the switch the field coils pass through various combinations, from all in series to all in multiple, the latter corresponding to the highest car speed. To stop the car, the switch is reversed, making the same combinations in reverse order. To change the direction of the car, a separate switch is generally provided, which changes the direction of the current through the armature with reference to its direction through the fields. In systems where there is no commutation of the field coils, the changes in speed depend entirely upon the variable amounts of extra resistance thrown into the circuit. The cars used on electric railways vary from 16 feet to 35 feet long, and weigh 6 to 11 tons.

ELECTRO-CHEMICAL ORDER OF THE ELEMENTS. When two metals are placed in contact and immersed in a solution capable of acting on one of them, an electric current is produced, positive electricity passing from the metal acted on, through the liquid, to the metal unacted on. The former metal is said to be *electro-positive* to the latter. By experimenting with different pairs, we can arrange the metals in electro-chemical order. This order depends upon the readiness with which the metals are acted upon by the solution, and is not the same for all solutions.

The following is the electro-chemical order of the more common metals, the liquid being dilute sulphuric or hydrochloric acid: Sodium, magnesium, zinc, iron, copper, silver, platinum. When a compound of two elements is electrolyzed, the electro-positive element appears at the negative electrode, and the electro-negative element at the positive electrode. It is impossible to make a single table of the electro-chemical order of the elements, as this is not the same under all circumstances, but it may be generally stated that oxygen is the most electro-negative element, and that next to it are the elements chlorine, bromine, fluorine, sulphur, etc., which form stable compounds with the metals.

ELECTRO-CHEMISTRY, OR ELECTROLYTICS. The name electrolysis (breaking up by electricity) is given to the process of transmission of the electric current through liquids, when accompanied by the disruption of the molecules composing the circuit; the constituent radicals of the molecules being set free at the two poles.

The plates in the decomposition cells are called electrodes (electric ways); the plate connected to the + pole of the battery, usually copper, platinum, or carbon, is the anode (way up, as carrying the current out of the battery); the plate connected to the — pole of the battery (the zinc) is the cathode (downward way).

The liquid undergoing decomposition is the electrolyte. The molecules of an electrolyte break up into two radicals, which are called ions (indicating individuality, and in another sense meaning "going"). Those ions which turn towards the anode are called anions. They are electro-negative or acid radicals, such as oxygen and chlorine. Those which turn towards the cathode are called cations. They are electro-positives or basic radicals, as hydrogen and metals. The same ion may belong at different times to each of these classes if united to one having a higher individuality in either direction, for there is no direct attraction between the electrodes and the ions themselves, but the relation depends simply upon the temporary polarity they assume in the circuit.

Ions or radicals may be single atoms or compounds, which act as radicals chemically, and these may even be incapable of actual separate existence as far as present knowledge goes. Hydrochloric acid is an electrolyte composed of two single atoms. In sulphuric

acid two atoms of hydrogen form one ion, and the compound radical, SO_4 , the other. This radical cannot exist uncombined, so that sulphuric acid is an electrolyte only when in presence of something it can react on and combine with, such as water, although water itself is not an electrolyte. Ammonium, NH_4 , is also a compound ion strongly resembling potassium in its properties; it also cannot exist free, but breaks up into NH_3 (ammonia) and hydrogen, giving an apparent exception to the law of equivalence, by producing two free substances, each equivalent to the current producing them; but it must be considered that ammonia is not really a radical, for NH_3 may be considered as the equivalent of a complete molecule and is not capable of replacing hydrogen in salts.

We must regard the circuit as consisting of chains of molecules, some metallic, as in the plates and conductors; some liquid, as in the cells; and the transmission of electricity, as consisting of a motion of each molecule in the chain, accompanied with the breaking in halves of a molecule wherever the current passes from metal to liquid, or vice versa. We shall thus understand why there is equal current, equal quantity of electricity, or equivalent chemical action at every section of the circuit. Because there are the same number (or value, as will be seen presently) of molecular actions effected at every part, however the molecules themselves may differ in nature. Each cell is, therefore, a section of the conductor, and each has its own specific resistance, just as the wire portion has. But the cells are of two orders in one respect.

(1) Generating cells, in which energy is set free by chemical actions, and becomes electro-motive force, setting up the current. These are battery cells, represented by E in electrical formulæ. (2) Decomposition cells, in which energy is absorbed in doing chemical work. These may be simple resistances, where no ultimate change is made in the solution; such are most electro-plating and electro-metallurgical processes where the same metal is dissolved from the anode as is set free at the cathode. But if any ions are actually set free by the current, they tend to recombine and act as a cell of the first order, with their electro-motive force opposed to that of the battery. This "counter E M F" is represented in formulas by $-e$, as is the electro-motive force of secondary batteries. See ELECTRICITY, STORAGE OF. The feeblest electro-motive force will send a current through the first of these classes of decomposition cells, but the second class require an E M F greater than that of opposition set up by the action itself, or electrolysis cannot take place, for the reason that no current will be produced if stopped by this counter E M F, as it is called. Except for this distinction of generating and decomposing, all the cells are under the same conditions. In each cell there is a $+$ plate or element, the zinc in the battery cells and the anode in the decomposition cells, and if the latter can unite to the chlorous radical of the electrolyte, it dissolves, just as the zinc does in the battery cells. In each cell there is the electrolyte which gives up its chlorous or $-$ ion, at the $+$ plate, and transmits the molecular motion, which constitutes the current to the $-$ plate where it also gives up its $+$ ion. The $-$ plate then continues as the $+$ pole or anode to the next cell, and ultimately to the $-$ pole or terminal zinc of the battery to complete the circuit. In fact, each pair of connecting plates in separate cells acts as though it were a metallic partition separating the two liquids with which the plates are in contact. In such a plate or conducting partition, one side would be $+$ and the other side $-$, and the two plates in different cells correspond to these two sides, united by a connecting wire instead of by the mass of metal of the plate itself. It is of the utmost importance to bear in mind this distinction of plates or elements related to the liquid within their own cell, and of poles or electrodes related to another cell, and to the direction of the polarity they set up, or the current they transmit. Leaving out of sight the distinction of cells, as those setting up and those absorbing energy, that plate in each cell which is $+$ to its own liquid, or the positive plate of the cell, is the anode or $+$ electrode of the cell to which it is connected, and completes the circuit from the $-$ plate of this cell. Hence it is that the anode in the decomposition cell represents the zinc in the battery cell, for, like the zinc, it is $+$ to the liquid, and gives up energy to the liquid (though that energy is derived from the current itself in this cell), and, like the zinc, it dissolves if made of materials which can combine with the negative or $-$ radical of the solution. For this reason some prefer to call the anode the zincode. The laws of electrolysis usually accepted are those of Faraday, who also originated the terms described. These laws are:

1. *No elementary substance can be an electrolyte. That is to say, the two ions must be differently composed.*

2. *Electrolysis occurs only while the body is in the liquid state.* This state may be due to either fusion or solution; in the latter case many substances which are not electrolytes of themselves may become electrolytes by a secondary action.

3. *During electrolysis the components of the electrolyte are resolved into two groups; one group takes a definite direction towards one of the electrodes, the other group takes a course towards the other electrode.* They turn towards the several electrodes in polar order, but are not attracted or moved towards them by a direct attraction of the polar electrodes. Faraday held that only substances containing single equivalents of each radical could act as electrolytes, but this is now superseded by more general conceptions.

4. *The amount as well as the direction of electrolysis is definite, and is dependent upon the degree of action in the battery being directly proportional to the quantity of electricity in*

circulation. This law shows that quantity of electricity means number of equivalent molecular actions.

5. *Those bodies only are electrolytes which are composed of a conductor and a non-conductor.* This addition of Miller's is useful to remember, but can scarcely take rank as a law or principle of nature.

It is of importance to learn what is the quantity of matter which constitutes the equivalent, as it is often considered to be what used to be called the chemical equivalent. If this were true, and if Faraday's theory were also true, that only molecules consisting of one equivalent of each radical are electrolytes, the old equivalent theory of chemistry would be almost impregnable; but neither of these ideas is true. The equivalent or lowest combining proportion of nitrogen is 14, that of hydrogen being 1; but when pure ammonia is electrolyzed, only $4\frac{1}{2}$ of nitrogen is given off for one of hydrogen. When cupric chloride, CuCl_2 , and cupreous chloride, Cu_2Cl_2 , are electrolyzed in series, the first gives one equivalent, and the second two equivalents of copper for the same current which in the battery or other cell gives one of hydrogen.

For practical applications in this field, see ELECTRO-METALLURGY, ELECTRO-CHEMISTRY, ELECTRO-PLATING. See also Sprague's *Electricity*.

ELECTRO-METALLURGY AND ELECTRIC SMELTING. Electro-metallurgy is the art of treating metals by the use of electricity. The birth of electro-metallurgy as a distinct branch of science may be said to have occurred in 1807, in which year Sir Humphrey Davy succeeded in producing metallic sodium and potassium by electrolysis of the fused hydrates in the laboratory of the Royal Institution, London. This new branch of study was followed up by Faraday in the same laboratory during the period from 1812 to 1840, and the results of his experimental work placed the science upon a firm basis of accurately observed phenomena, and led to the formation of laws and theories which are still accepted after fifty years of further progress. In 1851 Charles Watt obtained an English patent for electrolytic processes by which caustic alkalis and chlorine, chlorates and pure metals could be produced on an industrial scale, but it was not until 1890 that electro-metallurgy attained a commercial development. The chief cause of this delay was undoubtedly the lack of a cheap source of electrical energy. Until the latter year copper refining was the one electrolytic industry, but since that date there has been a remarkable expansion in other directions, and there are now at least 18 distinct branches, while in Europe alone there are about 100 establishments in which these manufactures are carried on. In recent years, since currents of great power have been made available by the invention of powerful dynamos, electro-metallurgical processes have been successfully carried on on a very much bolder scale than formerly, when they were confined to electro-plating. Electrolytic actions, which are the foundation of metallurgy, can be carried on when substances are in the liquid form. This form may be obtained by raising the temperature of the substances until they are in a state of fusion, as well as by putting them in solution, as in the processes described in the article on ELECTRO-PLATING (q.v.). This process of electrical decomposition of substances, when fused, has lately received many applications. In one of these it has been applied, in a very ingenious electrical furnace, illustrated herewith, to the work of separating a few very refractory substances from their ores.

By the passage of the decomposing currents between the electrodes in this furnace sufficient heat is developed to melt the minerals, thereby bringing them into the liquid condition, when the same current, by its decomposing action, separates the substance sought for, from the others, with which it is in chemical combination. The particular furnace shown, which has been in practical use at Lockport, N. Y., for some years, was especially designed for extracting from their natural earths, aluminium and other minerals which are difficult to obtain. See ALUMINIUM.

By means of this furnace several substances which contain valuable metals, but which were very hard to decompose, are easily torn apart and the metals obtained. By this furnace the production of large quantities of the aluminium bronzes, at prices low enough to compete with brass, has been accomplished and is now being carried on, while formerly, before the use of electricity for the purpose, the prices of these alloys were so high as to put them out of the question.

Electro-metallurgical and electro-chemical processes have made remarkable progress in the last ten years, and in 1897 there were in Europe and the United States 142 plants in operation, in which various products were made electrolytically. These may all be regarded as permanent industries, whose natural growth is assured by the purity and cheapness of the materials so manufactured. Besides these industries already established, new processes in this field are constantly being discovered. Among the more important processes are those for producing aluminium, copper, zinc, gold, silver and nickel, besides which there are a large number of materials such as sodium, potassium, white lead, calcium carbide, carborundum, etc., to which electrolytic processes are specially adapted.

Copper refining has become a very important industry, and the electrical process is an ideal one for extracting small amounts of impurities from commercial copper. There are 35 establishments for producing electrolytic copper, of which 16 are in the United States. The production of gold and silver by electrolytic methods is an assured industry, as in no other way can they be so easily and cheaply refined. In all gold mining districts where the cyanide extraction process is used the electrolytic method will be found extending. There are two such plants in Germany, 5 in the United States and 8 in the Transvaal. The manufacture of white lead will probably become an important one because the evils arising from lead poisoning in operating the older process have only been tolerated because no other satisfactory and economical method was formerly known.

The cheapening of the cost of electrical energy has been alluded to as the principal incentive to the extension of electro-metallurgical operations. The recent use of water-powers in this connection is very noticeable. In Europe there are in actual operation 16 companies which are utilizing water-powers for the manufacture of metallurgical products, and at the present time (1897) there are eight water-powers in course of development for similar processes.

In the United States the development of the water-power at Niagara Falls has led to the establishment of a number of metallurgical operations in that neighborhood. Large plants are established there for the manufacture of aluminium and carborundum, and a new plant has just been completed for the manufacture of sodium peroxide, which is used in the manufacture of hydrogen peroxide solution. The latter is extensively used for bleaching, and the peroxide of sodium is said to contain 12 times as much oxygen available for bleaching as the ordinary hydrogen peroxide solution.

The possibilities of electro-metallurgy seem almost infinite, and the field in this direction for new and valuable applications of electricity seems very promising, more especially as electrolysis seems to afford a means of accomplishing some chemical actions which are otherwise impossible.

ELECTROPHONE, an instrument devised by Dr. Strethill Wright for producing sound by electric currents of high tension. In its simplest form, the electrophone consists of two metallic plates separated by a sheet of cartridge-paper, the whole being closely pressed together by a heavy weight or screw. Such an instrument, when its plates are connected with the terminals of a small induction-coil, forms a sonorous condenser, the note of which varies with the rapidity of action in the electrotome or contact-breaker.

The more complicated electrophone communicated to the royal Scottish society of arts, 25th April, 1864, by Dr. Wright, is composed of four curved plates of the thinnest sheet zinc, each 2 by 4 ft., and each separated from its neighbor by a double layer of imitation silvered paper, the silvered sides being in apposition to the zinc. The first and third and second and fourth plates are connected by fine wires, which also connect the instrument with the induction-coil. When this instrument is connected with a small coil, the terminals of which afford a spark almost inaudible, it becomes charged and discharged with each impulse of current, each charge being attended by a sonorous tap given out by the whole mass of metal thrown into vibration, and the rapid succession of taps producing a prolonged trumpet-note, the power of which may be increased by adding battery-power to the coil. The electrophone has been recommended by its author for use as a telegraphic relay capable of giving two or four signs with a single wire, with the advantage over other relays that perfection of contact was not necessary to its working. Fig. 1 shows the mode of working the electrophone as a double relay with four signals and the galvanometer of Thomson; A represents the needle of the galvanometer, B and C the wires communicating with an electrophone. When the needle is deflected to the right, it falls on the points B and C, and sounds the electrophone through B, A, C. The signals are produced by long and short contacts, as in the code of Morse. The

FIG. 1.

The signals are produced by long and short contacts, as in the code of Morse. The

second set of signals is produced by the reversal of the line-current, which throws the needle on the points of the arrangement D connected with a second electrophone of different tone. The electrophone has been employed as a lecture-table instrument to report to a large audience results of processes which can only be rendered sensible by the most delicate galvanometric apparatus. Fig. 2 shows the adaptation of the electrophone to the galvanometer. AB represents the needle of the galvanometer suspended by a silk

FIG. 2.

fiber, C; D is a small vessel of mercury communicating by a fine wire with the center of the needle; while a similar wire, attached to the end of the needle B, dips into the curved trough EF, containing distilled water. The wires inserted into D and F connect the coil with the electrophone, the current passing through F, E, B, D. When the needle is deflected, the tract of water between E and F is shortened, and the electrophone gives forth a gradually increasing sound. By a delicate system of levers attached to the wrist, as in the sphygmograph (q.v.), the rhythm and character of the human pulse, and its variation in disease, may be indicated to the class by the physician. Further, the electro-

phone may be adapted to the telephone by making the telephone membrane act the part of a make-and-break for the current circulating in the primary wire of induction-coil. This can easily be done by leading the current through the membrane, and through a spring carrying a platinum point, which presses lightly against a piece of platinum attached to the center of the membrane. If the sounds uttered into the telephone be sufficiently strong to make the membrane so to vibrate as to cause actual separation between the platinum surfaces, they will be reproduced with great loudness in the electrophone; but if, as in the case of speaking, they be merely able to cause variations of pressure at the surfaces, they will be but imperfectly heard. Hence the electrophone succeeds best with singing (see TELEPHONE), and a song gently sung in one place may be repeated in trumpet-tones in another hundreds of yards distant.

ELECTROPHORUS. This generally consists of a tin mold filled with shellac, and a movable metal cover, with a glass handle. The shellac is poured in when melted, and it is mixed with some other substance, to make it less brittle. Five parts of shellac, one of wax, and one of Venice turpentine, is given as a good mixture. When used, the surface of the cake of shellac is smartly beaten with a cat's fur or foxtail. The cover is then put on, and touched with the finger, which receives a slight spark of - electricity, just before contact takes place; and after the finger is removed, the cover, when lifted by its insulating handle, gives a brisk spark of + electricity to anything presented to it. This can be repeated for several minutes without any apparent exhaustion of the source of electricity; and in dry weather, sparks can be got in this way hours, and frequently days after the cake has been beaten.

The action of the electricity may be thus accounted for. When the surface of the cake of shellac is beaten, the friction excites - electricity on it. This acts inductively all round, but the tin mold being the nearest conductor, and shellac a good dielectric, the induction becomes concentrated on it, + electricity becoming fixed on the side next the shellac, and - electricity being sent to the ground. The - electricity of the upper surface of the shellac is thus fixed by the + electricity of the mold. When the cover is put on the cake, the contact between the two is not sufficient to allow the latter to communicate its charge to the former. The cover is thus acted on inductively, not conductively. The - electricity of the cake, then, has the choice of two channels for its induction, either through the cake to the mold, or through a very thin film of air to the cover. The latter, from its offering so short a passage through the dielectric, has the preference, and the inductive action of the charge is diverted from the mold to the cover, and the + electricity on the other side of the cake is thus liberated and lost in the ground. The cover being strongly polarized, + electricity is induced and fixed on its lower surface, and - electricity on its upper, this last being transmitted to the ground by the finger. When the finger is withdrawn, and then the cover, the + electricity of the latter is free to discharge itself by spark, and inductive action again takes the direction of the mold, once more attracting + electricity to it. The induced polarity of the cover is attended with no loss to the charge of the shellac, which can thus continue to act with the same efficiency. The loss of electricity that all charged bodies experience in air, and especially when moist, at length discharges the cake, but this takes place all the less readily, that when the electricity is not needed to act on the cover, it is kept bound by the + electricity induced by it in the mold. In order that the + electricity of the mold should have liberty, so to speak, to come and go, the electricity must not be insulated; and when it is so, the action on the cover is feeble, if at all perceptible.

ELECTRO-PLATING. The decomposition of salts by the battery has received a most important application in electro-plating, or galvano-plastics, by which is meant

the art of precipitating certain metals from their solutions by the slow action of a galvanic current, by which means the salts of certain metals are decomposed, the metal being deposited on the negative pole, while the acid is liberated at the positive. The art was discovered independently by Spencer in England, and by Jacobi in Petersburg.

In order to obtain a galvano-plastic reproduction of a medal or any other object, a mold must first be made in which the layer of metal is deposited by the electric current.

For this purpose several substances are in use, and one or the other is preferred, according to circumstances. For medals and similar objects which can be submitted to pressure, gutta-percha may be used with advantage. The gutta-percha is softened in hot water, pressed against the object to be copied, and allowed to cool, when it can be detached without difficulty. For the reproduction of engraved wood blocks or type, wax molds are now commonly used. They are prepared by pouring into a narrow flat pan a suitable mixture of wax, tallow, and Venice turpentine, which is allowed to set, and is then carefully brushed over with very finely powdered graphite. While this composition is still somewhat soft, the wood block or type is pressed upon it either by a screw press or, still better, by hydraulic pressure. If plaster of Paris molds are to be made use of, it is essential that they be first thoroughly saturated with wax or tallow, so as to become impervious to water.

In all cases, whether the molds be of gutta-percha, of wax, or any non-conducting substance, it is of the highest importance that the surface be brushed over very carefully with graphite, and so made a good conductor. The conducting surface thus prepared must also be in metallic contact with a wire or a strip of copper by which it is connected with the negative electrode. Sometimes the molds are made of a fusible alloy, which may consist of 5 parts of lead, 8 of bismuth, and 3 of tin. Some of the melted alloy is poured into a shallow box, and just as it begins to solidify, the medal is placed horizontally on it in a fixed position. When the alloy has become cool, a slight shock is sufficient to detach the medal. A copper wire is then bound round the edge of the mold, by which it can be connected with the negative electrode of the battery, and then the edge and the back are covered with a thin non-conducting layer of wax, so that the deposit is only formed on the mold itself.

The most suitable arrangement for producing an electro-deposit of copper consists of a trough of glass, slate, or of wood, lined with india-rubber or coated with marine glue.

The figure shows one of glass. This contains an acid solution of copper sulphate, and across it are stretched copper rods, *a* and *e*, connected respectively with the negative and positive poles of a battery. By their copper conductors, the molds *B B B* are suspended in the liquid from the negative rod, while sheets of copper, *a a a*, presenting a surface about equal to that of the molds to be covered, are suspended from the positive rod at the distance of about 2 in., directly opposite to them.

The battery employed for the electric deposition of metals ought to be one of great constancy, and Daniell's and Smee's are mostly in use. The currents of electricity furnished by magneto-electrical machines of a special construction are also used in large establishments.

The copper plate suspended from the positive pole serves a double purpose: it not only closes the circuit, but it keeps the solution in a state of concentration, for the acid liberated at the positive pole dissolves the copper and reproduces a quantity of copper sulphate equal to that decomposed by the current.

Another and very simple process for producing the electric deposit of copper consists in making use of what is in effect a Daniell's cell. A porous pot or a glass cylinder covered at the bottom with bladder or with vegetable parchment is immersed in a vessel of larger capacity containing a concentrated solution of copper sulphate. The porous vessel contains acidulated water, and in it is suspended a piece of amalgamated zinc, of suitable form and having a surface about equal to that of the mold. The latter is attached to an insulated wire connected with the zinc, and is immersed in the solution of copper sulphate in such a position that it is directly opposite to the diaphragm. The action commences by the mold becoming covered with copper, commencing at the point of contact with the conductor, and gradually increasing in thickness in proportion to the action of the Daniell's element thus formed. It is, of course, essential in the process, to keep the solution of copper sulphate at a uniform strength, which is done by suspending in it muslin bags filled with crystals of this salt.

The extreme delicacy which such electric deposits can attain appears from the fact that galvano-plastic copies of the greatest accuracy can be made of daguerreotypes.

A novel process of electro-plating animals, flowers, tissues, and other natural objects, has been brought out in France. Slugs or snails are washed in water to clean them and then placed in distilled water until they give off their albuminous matter. This liquid is filtered and boiled for an hour; then distilled water is added to make up for that lost by boiling, and in addition about 3 per cent. of nitrate of silver. The solution is kept

in a dark place, in hermetically sealed bottles until required for use, when about 30 grammes of the liquid are mixed with about 100 grammes of distilled water. The objects to be electro-plated are then immersed for a few moments in the liquid, are next placed in a bath consisting of about 20 per cent. of nitrate of silver dissolved in distilled water, and are finally submitted to the action of sulphuretted hydrogen gas by which the nitrate of silver on the albumen-coated object is reduced. The organic object is thus fitted to receive the electro-deposited metal, and the layer obtained is of superior fineness and delicacy.

ELECTRO-POSITIVE ORDER OF THE ELEMENTS. As a voltaic current is produced whenever two metals are placed in metallic contact in a liquid which acts more powerfully upon one than upon the other, there is a great choice in the mode of producing such currents. In reference to their electrical deportment, the metals have been arranged in what is called an electro-motive series, in which the most electro-positive are at one end, and the most electro-negative at the other. Hence when any two of these are placed in contact in dilute acid, the current in the connecting wire proceeds from the one lower in the list to the one higher. The principal metals are as follows :

| | | |
|------------|-------------|--------------|
| 1 Zinc. | 6 Nickel. | 11 Gold. |
| 2 Cadmium. | 7 Bismuth. | 12 Platinum. |
| 3 Tin. | 8 Antimony. | 13 Graphite. |
| 4 Lead. | 9 Copper. | |
| 5 Iron | 10 Silver. | |

It will be seen that the electrical deportment of any metal depends on the metal with which it is associated. Iron, for example, in dilute sulphuric acid is electro-negative towards zinc, but is electro-positive towards copper ; copper, in turn, is electro-negative towards iron and zinc, but is electro-positive towards silver, platinum, or graphite.

The relative positions in this scale of the substances depend, somewhat upon the nature of the liquid in which they are placed.

ELECTROSCOPE is any instrument for the detection of the presence of electricity. It depends for its action on the principle that bodies charged with like electricity repel, while those charged with unlike electricity attract each other. The ordinary pith-ball is the simplest form of the instrument. The most perfect form is Bennet's gold leaf electroscope, but Cavallo's, Volta's condensing, and Bohnenberger's electroscopes are also used.

ELECTROTYPE, PHOTOGRAPHIC. Much thought and labor have been expended in producing a relief-plate to take the place of wood-engraving, and various methods of etching on metal by the aid of photography have been brought to light. The earlier of these never were successful, because after the acid has eaten or etched below the surface protected by the asphaltum, there is nothing to prevent it from undermining the lines, as the acid will eat in one direction as well as another, thus weakening them to such an extent that they often break down in printing. With the gelatine process, the gelatine must be of a thickness compatible with the depth desired. A gelatine of this thickness will become nearly, if not quite insoluble before it is dry, through the action of bichromate alone. Also the color of the gelatine, after the bichromate has been added, is such as to prevent the action of light from penetrating to the proper depth in the time during which it can be exposed. These are the almost insurmountable reasons why a relief-plate in gelatine has not been obtained till the advent of a new process called photo-electrotype. W. H. Mumler, of Boston, Mass., has now succeeded in overcoming these obstacles. After printing upon his gelatine, through a negative, the necessary time to secure all the details, the parts unaffected are dissolved away to a slight depth. The interstices are then filled with a black paste, when it is again exposed to light ; the soluble parts that were protected by the opacity of the negative in the first printing are now protected from the action of light by the black paste that covers them. The second exposure may be continued for a length of time sufficient to allow the light to penetrate its entire depth ; and the action of light being to render the gelatine insoluble, it can readily be seen that the protected parts can be dissolved away to the depth to which the light has penetrated. The gelatine relief is then placed in a drying closet for a few hours, when it becomes as hard as horn. From this an electrotype is taken in precisely the same manner as from a wood-cut. It is then mounted on mahogany blocks, type high, when it is ready for the press. The result is an electrotype plate with a surface as smooth as polished plate-glass, and a depth far exceeding that of ordinary wood-cuts. See PHOTOGRAPHY.

ELECTROTYPING. The process of forming exact reproductions of type, wood-cuts, and so forth by means of the process of electro-plating (q.v.). See also **ELECTRO-METALLURGY** ; **ELECTRO-CHEMISTRY**. Electrotypes are very much used in printing on account of their furnishing inexpensive and perfectly accurate reproduction of the original. By their use many complete sets of type for printing are quickly obtained, and the original type is saved from the great wear which would result from the direct printing from them of many thousands of copies.

ELECTRUM is a term used to designate native gold as it is associated with silver. It is also applied to amber.

ELECTUARY (Lat. *eligere, electum*, I make choice), a form of medicinal preparation in which the remedy is enveloped or suspended in honey or syrup, so as to make a mixture of thick semi-fluid consistence.

ELEGIT, ESTATE BY, the right in lands which is enjoyed by one who has acquired the land under writ of elegit (q.v.)

ELEGIT, WRIT OF, a writ whereby a creditor in England can seize the lands of his debtor in satisfaction of his claim. By 1 and 2 Vict., c. 110, the whole of the lands, including copyhold and customary lands, are made subject to the debt. A creditor who has seized the lands is not entitled to take the person of his debtor; for, as imprisonment for debt is practically abolished, except where fraud was used, this and *fieri facias* (q.v.) are the only remedy of creditors.

ELEGY (Gr. *elegeia*), according to its derivation, signifies, exclusively, a song of lamentation, but the term was employed at an early period by the Greeks to designate any poem written in distiches. The alternation, peculiar to this measure, of the hexameter, or strictly narrative verse, with the more fiery pentameter, gives to this whole species of poetry its individual character, which consists in the connection of subjective feelings and emotions with external incidents or objects. The E., therefore, can often be chiefly, but never altogether narrative. The effect of the measure is further shown in the circumstance, that earnest, long-sustained feelings, rarely violent passions, are expressed in the elegy. Of the numerous elegies of the Greeks, few have come down to us. Those still extant consist partly of encouragements to patriotism, as in Callinus and Tyrtaeus, and partly of lessons of practical wisdom, as in Solon and Theognis. Sometimes also it expressed yearning desire or mild sorrow, or amorous complaints. This was especially the case at Alexandria. Among the Romans, Catullus was the first good elegiac writer; after him came Propertius, Tibullus, and Ovid. Tibullus, in particular, brought the erotic E. to its highest perfection. All are marked by the absence of political or moral feeling. They lived at a time when it was dangerous to express the one, and unfashionable to express the other—viz., the Augustan age. In modern times, the term E. is applied in England to any serious piece where a tone of melancholy pervades the sentiments, whether grief is actually expressed or not; as, for example, Gray's "*Elegy*, written in a country church-yard."

ELEGY, in music, is a composition depicting feelings of mourning, sadness, longing or ardent desire, and love.

ELEMENTAL SPIRITS, beings who, according to the popular belief of the middle ages, presided over the four "elements," living in and ruling them. The E. S. of fire were called salamanders; those of water, undines; those of the air, sylphs; and those of the earth, gnomes. These imaginary beings play a part in Pope's mock-heroic poem, *The Rape of the Lock*.

ELEMENTS, in astronomy, are those numerical quantities, and those principles deduced from astronomical observations and calculations, which are employed in the construction of tables exhibiting the planetary motions. They include the greatest, least, and mean distances of the planets from the sun, the eccentricities of their orbits, their mean motions, daily and annual, with the motions of their aphelia, and the inclinations of their orbits to the ecliptic; their masses and densities, etc. The E. of the different planets and of their satellites will be found under their names. The reader will find tables of the E. of all bodies in our system in most books on astronomy. See in particular Herschel's *Elements of Astronomy*.

ELEMENTS, CHEMICAL. The word elements has a very different signification in modern science from what it once had. The earliest of the Greek philosophers assumed either a single element, or several, the modifications and combinations of which they held to give rise to all the things that we see. The most common assumption was that of four elements—fire, air, water, and earth. This corresponds to the four forms under which modern science considers matter as existing—viz., imponderable, gaseous, liquid, and solid; while by elements are understood the simple component ingredients of bodies under whatever form they exist. Neither air, water, nor earth are elements in this sense, for they can be decomposed into simpler ingredients, and fire is a combination of light and heat. It is not pretended that any of the substances called elements are absolutely simple, that is, contain only one kind of matter; but only that hitherto they have not been decomposed. The number of so-called simple bodies, or elements, recognized by chemists is 65, of which some have been known from ancient times, such as the metals gold, silver, lead, copper, tin, and mercury; others are of more recent date; whilst quite lately two new metallic elements have been added to the list—viz., cæsium and rubidium, both of which were discovered by prof. Bunsen of Heidelberg, by the aid of the new branch of practical chemistry named *spectrum analysis*. The elements are divided into two great classes—the *non-metals* and *metals*. The latter are the more numerous class, there being altogether 50, whilst the non-metals number only 15. The following table gives the names of the elements at present known:

TABLE OF THE ELEMENTARY SUBSTANCES.

| <i>Non-metallic.</i> | | | |
|------------------------|-------------------|--------------------|----------------------|
| Hydrogen. | Oxygen. | Nitrogen. | Carbon. |
| Chlorine. | Sulphur. | Phosphorus. | Boron. |
| Bromine. | <i>Selenium.</i> | Arsenic. | Silicon. |
| Iodine. | <i>Tellurium.</i> | | |
| Fluorine. | | | |
| <i>Metallic.</i> | | | |
| Potassium. | Copper. | Nickel. | <i>Tantalum (Co-</i> |
| Sodium. | Silver. | Cobalt. | <i>lumbium).</i> |
| <i>Lithium.</i> | Mercury. | Chromium. | <i>Niobium.</i> |
| <i>Cæsium.</i> | <i>Yttrium.</i> | <i>Molybdenum.</i> | Gold. |
| <i>Rubidium.</i> | <i>Cerium.</i> | <i>Tungsten.</i> | Platinum. |
| Calcium. | <i>Lanthanum.</i> | <i>Uranium.</i> | <i>Iridium.</i> |
| Barium. | <i>Didymium.</i> | Tin. | <i>Osmium.</i> |
| Strontium. | <i>Erbium.</i> | <i>Titanium.</i> | <i>Ruthenium.</i> |
| <i>Beryllium (Glu-</i> | <i>Terbium.</i> | <i>Zirconium.</i> | <i>Rhodium.</i> |
| <i>cinium).</i> | Aluminum. | <i>Thorium.</i> | <i>Palladium.</i> |
| Magnesium. | <i>Indium.</i> | <i>Vanadium.</i> | |
| Zinc. | <i>Gallium.</i> | Antimony. | |
| <i>Cadmium.</i> | Manganese. | Bismuth. | |
| Lead. | Iron. | | |
| <i>Thallium.</i> | | | |

The more rare elements are printed in *italics*. Although the classification adopted above is a convenient one for the study of the elements, yet there is no decided line of demarkation between the metallic and non-metallic (otherwise called metalloïd) series. The metals are generally recognized (1) by their power of reflecting light, as exhibited in the luster of burnished gold, and even in ordinary mirrors, which owe their power of reflecting light to the amalgam of the metals mercury and tin, present on the glass; (2) by their power of conducting heat; and (3) by their ready transmission of electricity. The non-metals or metalloïds are regarded as not possessing all these three attributes. The non-metals carbon and silicon, however, in certain forms conduct electricity, whilst the metals arsenic and tellurium resemble the metalloïds in many of their properties, and are classed with them. In the combinations of the various elements with each other, the non-metals constitute the electro-negative ingredient, and, as a rule, are insulators in the galvanic current; whilst the metals form the electro-positive element of the combination, and are conductors of the electric fluid. Again, in their combination with oxygen, the non-metals form more or less powerful acids, whilst the metals produce more or less powerful bases. At ordinary temperatures, five of the E. are gaseous—viz., oxygen, hydrogen, nitrogen, chlorine, and fluorine; two are liquid—viz., bromine and mercury; whilst the remaining 58 are solid.

Steady progress in chemical science presents the names of several substances which claim admission to the list of elements, with varying degrees of confidence. All are constituents of rare minerals, and none of them are likely to acquire much importance in practical affairs. The small quantities yet found have made the discussion of their oxygen compounds very difficult, and leave their appropriate atomic weights liable to different determinations.

The following list gives their status as known in Aug., 1884:

| Name. | Symbol. | At. w't. | Discoverer and Remarks. |
|-----------------|---------|------------|---|
| Thulium..... | | 171 | Cleve, 1880. |
| Gallium..... | Ga. | { 69.9 } | Lecoq de Boisbaudran, 1875. White, sp. gr. 5.93, melts at 30.16°. |
| Decipium..... | Dp. | Doubtful. | M. Delafontaine. 106=DpO, 159=Dp ² O ³ . |
| Phillipium..... | Pp. | " | M. Delafontaine in 1880 gave 123 or 125. |
| Ytterbium..... | Yt. | 173.1 | M. Marignac. |
| Scandium..... | Sc. | 43.97 | L. F. Nilson, 1880, in a Scandinavian mineral. |
| Norwegium..... | Ng. | { Doubt- } | Teleff Dahll, in copper-nickel, color white, melts at 254°. |
| | | { ful. } | Sp. gr. 9.441. 145.95=RO, 218.93=R ² O ³ . |

F. W. Clarke (*Chemical News*, 1884), gives the following as imperfectly determined: Titanium, Tellurium; badly determined, Palladium, Rhodium, Ruthenium; very badly determined, Silicon; doubtful, Yttrium, Zirconium; very doubtful, Osmium. Prof. Robinson (Cambridge, Eng.) thinks Bührig's atomic weight for Cerium too high. Samarium needs confirmation. Phillipium may be Holmium. See L. Meyer and K. Seubert's *Atomgewichte der Elemente* (Leipzig, 1883). See CHEMICAL NOMENCLATURE; CHEMISTRY.

ELEMENTS, SACRAMENTAL. The materials used in the communion service are usually recognized as bread and wine, but some ancient sects used bread and water, and the Syrian Christians mix oil and salt with the bread. See LORD'S SUPPER.

E'LEMI, a fragrant resinous substance, obtained from different species of the natural order *amyridaceæ*. It was formerly brought chiefly from Egypt or Ethiopia, and was referred to a tree called *amyris elemifera*. Part of the E. of commerce is now brought from America, and is obtained from trees of other genera, but of the same natural order, particularly *icica icicariba*, which grows in Brazil and other warm parts of America. In dry weather, incisions are made in the bark, from which the resinous juice flows abundantly, and hardens in the sun. It is collected once a day, and put into casks. It is at first soft and unctuous, but becomes hard and brittle by age. *Elaphrium elemiferum* is believed to yield the greater part of the E. of Mexico. E. is usually in large, pale-yellow, semi-transparent masses, fragile, softening by the heat of the hand, with a smell somewhat resembling that of fennel. It is soluble in alcohol, except a white crystallizable residue, which is very light, inodorous, and tasteless, and which is called *elemine*. The properties of E., however, chiefly depend on a volatile oil, which may be obtained from it by distillation. E. is used in the preparation of stimulant plasters and ointments.

ELEPHANT, a geographical term of obvious origin, indicates various localities in Asia and Africa.—1. Elephant point, a promontory of Pegu, in Further India, marks the w. extremity of the mouth of the Rangoon, the most easterly arm of the Irrawaddy. It is in lat. 16° 28' n., and long. 96° 25' east.—2. Elephant bay, an inlet of the Atlantic, on the coast of Benguela, s.w. Africa, in lat. 18° 14' s., and long. 12° 33' e., has excellent anchorage, but no fresh water.—3. Elephant island, in Senegambia, is about 100 m. up the Gambia.—4. Elephant river, in the Cape Colony of South Africa, enters the Atlantic after a course of 140 m., about lat. 31½° s., and long. 18° east.

ELEPHANT (Gr. *elephas*), a genus of quadrupeds, of the order *pachydermata* (q. v.), and of the section *proboscidea*. Elephants are the largest existing land animals. The ordinary height at the shoulder is about 8 ft., but sometimes exceeds 10 feet. The weight of a large E. is about five tons, the body being very bulky in proportion to its height. To sustain this weight, it is furnished with limbs of colossal thickness and strength, which are also remarkably straight, each bone resting vertically on that beneath it. From the appearance of inflexibility presented by the limbs, arose the notion prevalent among the ancients, and throughout the middle ages, that the limbs are destitute of joints, and that consequently an E. cannot lie down to rest like another quadruped, and if it were to lie down, could not rise again, but always sleeps standing, or leaning against a tree. It is indeed true that the E. often sleeps standing, and when fatigued, falls asleep leaning against a rock or tree, against which it may have been rubbing itself. The flexibility of the limbs is, however, sufficient to permit elephants to run with speed nearly equal to that of a horse, to indulge in playful gambols, and to ascend and descend steep mountains. Elephants are more sure-footed and serviceable than either horses or mules, in difficult mountain roads. On the very steepest declivities, an E. works his way down pretty rapidly, even with a *howdah* and its occupants upon his back, his chest and belly on the ground, and each forefoot employed in making a hole for itself, into which the hind-foot afterwards follows it, and to which the weight may be trusted, that another step may be ventured with safety. In lying down, the E. does not bring his hind-legs under him, like the horse and other quadrupeds, but extends them backwards (as man does when he assumes the kneeling position), an arrangement which, "by enabling him to draw the hind-feet gradually under him, assists him to rise almost without a perceptible effort." The E.'s pace, when exceeding a walk, is neither a trot nor a gallop, which would be too violent a motion for its conformation and huge body, but a sort of shuffle, the speed of which is increased or diminished without other alteration. The E. is incapable of springing like the deer, horse, and other animals which have the bones of their shoulders and hocks set at an angle.

The head in elephants is large; the neck is short and thick, the long flexible proboscis compensating both for the shortness of the neck, and for the inflexibility caused by the largely developed processes of its vertebræ, and enabling the animal readily to reach objects on the ground, or to a height of several feet above its head, or on either side. A great extent of bony surface in the head affords attachment for muscles destined to move and give power to the proboscis or trunk. This extent of bony surface is provided in a remarkable manner, which at the same time makes the head, heavy as it is, lighter in proportion to its bulk than is usual in quadrupeds; a great space separating the internal and external tables of all the bones of the skull, except the occipital bones, so that the space occupied by the brain is but a small part of the whole head. The space between the tables of the bones is occupied by cells, some of which are 4 or 5 in. in length; others are small, irregular, and honeycomb-like; "these all communicate with each other, and through the frontal sinuses with the cavity of the nose, and also with the tympanum or drum of each ear; consequently, as in some birds, these cells are filled with air." The huge and extraordinary bones of the skull, besides affording attachment for muscles, afford mechanical support to the tusks.

The nasal bones of the E. are scarcely more than rudimentary; but the tapering proboscis, to the very extremity of which the nostrils are prolonged, is nearly 8 ft. in length. Besides the great muscles connected with it at its base, it is composed of a vast multitude of small muscles variously interlaced, but chiefly either longitudinal, and divided into successive arcs, of which the convexity is outwards, or transverse, and

radiating from the internal to the external membrane. Cuvier states the number of muscles having the power of distinct action as not far short of 40,000. The trunk can be coiled around a tree, and employed to tear it from its roots; it is a formidable weapon of offense or defense, and is far more employed in this way than the tusks, even by those elephants which have tusks of great size; its extremity can be wound around a small handful of grass or a slender branch; it is even capable of plucking the smallest leaf, or of lifting a pin from the ground. To fit it for such actions as those last mentioned, and for many such as might be performed by a hand, it is furnished at the extremity with what may be likened to a finger and thumb; on the upper side, an elongated process—strong, soft, and flexible, like the rest of the trunk, and endowed with the most delicate sense of touch—on the under side, a kind of tubercle against which this process may be pressed. All the food of the E. is gathered and conveyed to the mouth by the trunk: by means of the trunk, also, it drinks, sucking up into it a quantity of water sufficient to fill it, and then discharging the contents into the mouth. Valves at the base of the trunk prevent the water from going too far up the nostrils. The trunk is constantly employed by elephants in providing in many ways for their comfort or enjoyment, as in throwing dust over their backs, or in fanning themselves and switching away flies with a leafy branch, two practices to which they are greatly addicted. Their mutual caresses are also managed by means of the trunk, and through it they make a loud shrill sound, indicative of rage, which is described by Aristotle as resembling the hoarse sound of a trumpet, and from which this organ received its French name *trompe*, corrupted in English into trunk. With the trunk, also, they sometimes, when angry, beat violently on the ground.

The sense of smell is very acute in the E., as is also that of hearing. The ears are large and pendulous; the eyes are small.

Elephants have no canine teeth, nor have they any incisors in the lower jaw. The upper jaw is furnished with two incisors, which assume the peculiar character of tusks, and attain an enormous size, a single tusk sometimes weighing 150 or even 300 pounds. The tusks are, however, often imperfectly developed, 10 or 12 in. in length, and 1 or 2 in diameter. These stunted tusks are often used for such purposes as snapping off small branches and tearing climbing plants from trees. Those elephants which possess great tusks employ them also for such other uses as loosening the roots of trees which they cannot otherwise tear from the ground; or in a state of domestication, for such labors as moving great stones, and piling or carrying timber. A powerful E. will raise and carry on his tusks a log of half a ton weight or more. The tusks of the E. surpass in size all other teeth of existing animals, and are the largest of all teeth in proportion to the size of the body. They consist chiefly of that variety of *dentine* called ivory (q. v.), and continue to grow—like the incisors of the rodents, to which they are in some respects analogous—even when the animal has attained a great age, if not to the very end of its life. The young E. is at first furnished with deciduous incisors, which are shed between the first and second year, and are succeeded by the permanent tusks.—The molar teeth of the E. are developed in succession; and at least in the Indian E., never more than two are to be seen in the same side of a jaw at one time. The first molars cut the gum in about two weeks after birth, and are shed about the end of its second year. The sixth molars, which are also believed to be the last, are supposed to appear about the fiftieth year of the E.'s life. The molar teeth of the E. are remarkable for their great size, and for the extreme complexity of their structure, to which the nearest resemblance is found in some of the small rodents. They are composed of vertical plates of bony substance, separately enveloped in enamel, and cemented together by a third substance, called *crusta petrosa*, *cortical*, or *cement*, more resembling bone than enamel. Each succeeding tooth is not only more complex, but occupies a greater space in the jaw than its predecessor. Although formed from a single pulp, the molar tooth of an E. resembles an aggregation of teeth; and in the earlier stages of its growth, when the cement is not yet deposited, it seems as if many separate teeth were soldered together. As the surface of the tooth is worn down by mastication, the harder enamel is exposed in elevated ridges. The whole of a tooth is not in employment at once. From the peculiar manner of its growth, the anterior part begins to be employed, and to be worn away, whilst the latter part is still in process of formation.

The digestive apparatus of the E. is similar to that of the other pachydermata; but the stomach, which is of a very lengthened and narrow form, exhibits a peculiarity which assimilates it to that of the camel; the internal membrane, at the extremity beyond the cardiac orifice, forming thick wrinkles and folds, the broadest of which, and nearest to the gullet, seems to act as a valve, making that end of the stomach a reservoir for water, capable of containing about ten gallons; whilst a peculiar muscle, connecting the windpipe and gullet, enables the animal to open this reservoir at pleasure, for the regurgitation of the fluid, which is then sometimes received into the trunk, and squirted over the body, to free it from the nuisance of flies or the heat of a tropical sun.

The female E. has only two teats, situated between the fore-legs. The young suck with the mouth, and not with the trunk. They are suckled for about two years. The period of gestation is also nearly two years, and a single young one is produced at a birth.

The skin of the E. is very thick, of a dark-brown color, and in the existing species has scarcely any covering of hair. The tail does not reach to the ground, and has a tuft of coarse bristles at the end. The feet have in the skeleton five distinct toes, but these are so surrounded with a firm horny skin that only the nails are visible externally, as on the margin of a kind of hoof. The foot of the E. is admirably adapted for steep and rough ground, the protective skin which covers the toes allowing them considerable freedom of motion.

Only two existing species of E. are certainly known, the Indian (*E. Indicus*) and the African (*E. Africanus*), although differences have recently been observed in the E. of Sumatra, which may perhaps entitle it to be ranked as a distinct species. Elephants are found in all parts of Africa, from the Sahara southwards, where wood and water are sufficiently abundant; also throughout India and the south-eastern parts of Asia, and in some of the tropical Asiatic islands. They extend northwards to the Himalaya; and Chittagong and Tiperah vie with Ceylon in the superior excellence of the elephants which they produce. The Indian E. is distinguished by a comparatively high oblong head, with a concave forehead; whilst the African has a round head and convex forehead. The ears of the African E. are much larger than those of the Indian, covering the whole shoulder, and descending on the legs. A marked distinction of the two species is also found in the molar teeth; those of the Indian E. exhibiting *wavy parallel transverse ridges*; whilst those of the African species have the divisions of the crown of the tooth fewer, broader, and *lozenge-shaped*.

Elephants live in herds, not generally numerous, but several herds often congregate together in the same forest or at the same place of drinking. Each herd has a leader, generally the largest and most powerful animal. The leader seems to exercise much control over the movements of the herd, gives the alarm in case of danger, and seems to examine and decide for the whole herd as to the safety of proceeding in any particular direction. On account of his tusks, the leader is very often the animal against which the efforts of the hunter are directed; but the rest of the herd do their utmost to protect him, and when driven to extremity, they place him in the center, and crowd so eagerly to the front of him that some of them must often be shot ere he can be reached. A family resemblance is usually very visible among the elephants of the same herd; some herds are distinguished by greater stature, and others by more bulky form and stronger limbs; some by particularly large tusks, some by slight peculiarities of the trunk, etc. In the East Indies, distinctions of this kind have long been carefully noticed, and particular names are given to elephants according to them, some being considered as *high-caste*, and others as *low-caste* elephants. An E. which by any cause has been separated from its herd, seems never to be admitted into another, and these solitary elephants are particularly troublesome, in their depredations exhibiting an audacity which the herds never exhibit; they are also savage and much dreaded, whilst from a herd of elephants danger is scarcely apprehended. The E. is generally one of the most inoffensive of animals, although in a state of domestication, it shows, as is well known, a power both of remembering and resenting an injury.

The favorite haunts of wild elephants are in the depths of forests—particularly in mountainous regions—where they browse on branches, and from which they issue chiefly in the cool of the night to pasture in the more open grounds. They are ready to plunder rice or other grain-fields, if not deterred by fences, of which, fortunately, they have, in general, an unaccountable dread, even although rather imaginary than real. A fence of mere reeds will keep them out of fields, where, as soon as the grain is removed, they enter by the gaps of the fence, and may be seen gleaning among the stubble.

When the E. eats grass, "nothing can be more graceful than the ease with which, before conveying it to his mouth, he beats the earth from its roots by striking it on his fore-leg." A cocoa-nut is first rolled under foot, to detach the outer bark, then stripped of the fibrous husk, and finally crushed between the grinders, when the fresh milk is swallowed with evident relish. The fruit of the palmyra palm is another favorite food of elephants, and they seem to have an instinctive knowledge of the time of its ripening. Sugar-canes are also a favorite food; indeed, elephants are very fond of sweet things. Those which are brought to Britain are generally fed on hay and carrots. The amount of daily food necessary for the E. in a state of domestication may be stated, on an average, at about 200 lbs. in weight.

Elephants delight in abundance of water, and enter it very freely, often remaining in it for a considerable time and with great evident enjoyment. They sometimes swim with not only the body but the head under water, the only part elevated above it being the extremity of the trunk.

The habits of the African E. appear in no important respect to differ from those of the Indian elephant. It is the latter only that is at the present day domesticated; but it is certain that the African species was anciently domesticated, and the figures on many Roman medals attest it.

Elephants rarely breed in a state of domestication, although, a few years ago, the birth of an E. took place in the zoological gardens of London, an occasion of much interest not only to the scientific but to the general public. They are generally tamed within a few months after they are captured; some degree of severity being employed

at first, which, however, as soon as the animal has begun to respect the power of man, is exchanged for kindness and gentleness of treatment. Elephants intended for domestication are captured in various ways. It was formerly common to take them in pitfalls, but in this way they were often much injured. Another method frequently practised is by the aid of tame elephants. Male elephants chiefly are captured in this way, the decoy elephants employed being females, trained for the purpose. With these the hunters very cautiously approach the animal they mean to capture, and he generally permits them to come up to him, and is so pleased to make the acquaintance of the female, that he takes no notice of their riders and other human attendants. Two of the females take their places, one on each side of him, and whilst he is occupied with them, men, the profession of whose lives it is, and who display a wonderful expertness in the work, contrive to get beneath their bodies, and to pass ropes round the legs of the intended captive. His two hind-legs are fastened together by 6 or 8 ropes in the form of the figure 8, another rope keeping them tight at the intersections, and a strong cable with a running-noose is attached to each hind-leg. About twenty minutes are usually spent in fixing the necessary ropes, profound silence being maintained if the process goes on unobserved, or some of the other hunters distracting the attention of the E. from those who are engaged in this work; and when at last, becoming sensible of his danger, he tries to retreat, an opportunity is soon found of tying him, by means of the long cables which trail behind him, to some tree strong enough for the purpose. His fury then becomes ungovernable, and he makes violent and prodigious efforts to get free, throwing himself on the ground, and twisting himself into the most extraordinary positions. It is not until he has thoroughly exhausted himself, and begins to suffer severely from fatigue, thirst, and hunger, that the next steps are taken towards taming him and making him a willing servant of man.

Still more wonderful is the capture of a wild E., sometimes by not more than two hunters, who for this purpose will go into the woods, without aid or attendants, their only weapon a flexible rope of hide. With this they secure one of the E.'s hind-legs, following his footsteps when in motion, or stealing close up to him when at rest, or sometimes spreading the noose on the ground, partially concealed by roots and leaves, beneath a tree on which one of the party is stationed, whose business it is to lift it suddenly by means of a cord. When arrested by the rope being coiled around a tree, the E. naturally turns upon the man who is engaged in making it fast, but his companion interferes on his behalf, by provoking the animal; and thus not only is the first rope made fast, but noose after noose is passed over the legs, until all are at last tied to trees, and the capture is complete; upon which the hunters build a booth for themselves in front of their prisoner, kindle their fires for cooking, and remain day and night till the E. is sufficiently tamed to be led away.

But these huge animals are not always captured singly; whole herds are often taken at once. This is accomplished by means of an inclosure, towards which the elephants are driven by great numbers of men encircling a considerable space, and contracting the circle by slow degrees. Weeks, or even months, are spent in this operation, and at last the elephants, hemmed in on every side except the mouth of the inclosure, enter it, and the gate is immediately closed. The modes of constructing the inclosure are different in different parts of the east. Tame elephants are sometimes sent into it, and the captives are in succession made fast to trees there, in a way somewhat similar to that practiced in capturing single elephants.

The E. first became known in Europe from its employment in the wars of the east: "in India, from the remotest antiquity, it formed one of the most picturesque, if not of the most effective, features in the armies of the native princes." Elephants have been taught to cut and thrust with a kind of scimitar carried in the trunk, and it was formerly usual for them to be sent into battle, covered with armor, and bearing towers on their backs, which contained warriors. But the principal use of the E. in war is for carrying baggage, and for dragging guns. An E. will apply his forehead to a cannon, and urge it through a bog, through which it would be almost impossible for men and cattle to drag it; or he will wind his trunk round it, and lift it up, whilst horses or cattle drag it forwards. Elephants are used in the east for carrying persons on their backs, a number being seated together in a *howdah*, whilst the driver (*mahout*) sits on the E.'s neck, directing it by his voice and by a small goad. Elephants have always a conspicuous place in the great processions and state displays of eastern princes, and white elephants—albinos—are peculiarly valued. Elephants are also employed in many kinds of labor, and display great sagacity in comprehending the nature of their task and adapting themselves to it. In piling timber, the E. "manifests an intelligence and dexterity which is surprising to a stranger, because the sameness of the operation enables the animal to go on for hours disposing of log after log, almost without a hint or direction from his attendant."

Of the sagacity of the E., many interesting anecdotes are on record, as every reader of books of travels and of natural history knows. But Cuvier refuses, and apparently with justice, to ascribe to it a degree of sagacity higher than that of the dog. In a state of domestication, the E. is a delicate animal, requiring much watchfulness and care, although naturally it has a very long life, and instances are on record of extreme longevity in domestication, extending not only to more than one hundred, but almost to two hundred years.

The numbers of wild elephants, in some parts both of the East Indies and of Africa,

are being gradually reduced as cultivation extends, and many are shot for no other reason than a desire to reduce their numbers, and put an end to their ravages on cultivated grounds. A reward of a few shillings per head was claimed for 3,500 destroyed in part of the northern province alone of Ceylon, in less than three years prior to 1848. It is for the sake of ivory that the greatest slaughter of elephants takes place. A ball of hard metal, skillfully planted in the eye, base of the trunk, or behind the ear, generally ends an E.'s life in an instant; and expert *sportsmen* have been known to kill right and left one with each barrel.

Fossil Elephants.—The E. makes its appearance in the pleistocene strata. Its nearly ally, the mastodon, whose remains are found associated with it, began life earlier; it has left its traces in miocene deposits. Ten species of fossil elephants have been described, the remains of three of which are found in Europe. The best known of these is the *elephas primigenius*, or mammoth, the tusks of which are so little altered as to supply an ivory which, though inferior to that of the living species, is still used in the arts, especially in Russia. Its tusks are, on this account, regularly searched for by "ivory hunters" in Siberia, where, in the superficial deposits of sand, gravel, and loam, the remains occur in enormous abundance. They are also found in similar strata all over Europe. In Britain, the localities that have supplied these remains are very numerous. They are especially abundant in the pleistocene deposits of the e. and s.e. of England. Woodward, in his *Geology of Norfolk*, calculates that upwards of 2,000 grinders of this animal had been dredged up by the fishermen off Happisburgh in thirteen years. The bone-caves also yield remains of this gigantic animal.

The mammoth truly belongs to the geological history of the world; it died out at the close of the period represented by the pleistocene beds. It is the only fossil animal that has been preserved in a perfect condition for the examination of man. In all other remains we have to deal with the hard portions only—the bones, teeth, scales, etc., and frequently only with fragmentary portions, requiring the skill of a Cuvier or an Owen to make from them an approximation to the perfect animal. But the mammoth has been preserved so that its flesh has been eaten by dogs, bears, and wolves. In 1799, a Tungusian, named Schumachoff, while searching along the shores of lake Oncoul for mammoth tusks, observed among the blocks of ice a shapeless mass, but did not at the time discover what it was. The heat of succeeding summers gradually melted the ice around it, and, in 1803, the mammoth fell on a bank of sand. In Mar. of the following year, the hunter visited it, cut off, and carried away the tusks, which he sold for fifty rubles. In 1806, Mr. Adams visited the locality, and examined the animal, which still remained on the sand-bank where it had fallen, but in a greatly mutilated condition. The Jakutski of the neighborhood had cut off the flesh to feed their dogs, and the wild beasts had almost entirely cleared the bones. The skeleton was, however, entire, excepting one of the forelegs, and some of the bones of the tail. Many of the bones were still held together by the ligaments and by parts of the skin. The head was covered with dry skin; one of the ears was well preserved; it was furnished with a tuft of hairs. Three fourths of the whole skin were procured, which was so heavy that ten persons found great difficulty in transporting it to the shore, a distance of 150 ft.; it was of a dark-gray color, and was covered with a reddish wool, and long black hairs or bristles. The wool was short, and curled in locks; the bristles were of different lengths, varying from 1 to 18 inches. Some of this covering still remained attached to the skin, but the great mass was entirely separated from it. Mr. Adams collected 36 lbs., although much of it had been destroyed from the dampness of the place where it had lain so long. The animal was a male, and had a long mane on the neck. The entire carcass was removed to St. Petersburg, where it is now preserved. The tusks were repurchased, and added to the animal. It measures from the fore part of the skull to the end of the mutilated tail 16 ft. 4 in.; the height to the top of the dorsal spines is 9 ft. 4 in.; the length of the tusks along the curve is 9 ft. 6 inches. Portions of the hairy covering have been brought to this country, and may be seen in the British museum.

Taking the teeth as exhibiting clearly a marked difference in the recent species, the mammoth is easily separated from both by its broader grinders, which have narrower, and more numerous, and close-set plates and ridges. The existence of the E. and other genera, whose representatives are now found only in the warmer regions of the earth, in the n. of Europe and Asia, led to the belief, that at the recent period in the world's history when they were its living inhabitants, a tropical temperature existed in the temperate zone, and stretched further n. towards the pole; but the discovery of this perfect animal showed that these huge elephants were adapted by their clothing to endure a cold climate, and by the structure of their teeth were able to employ as food the branches and foliage of the northern pines, birches, willows, etc. There are few generalizations more plausible at first sight than to predicate of an unknown species of a genus what is ascertained regarding the known members of the same genus. It required a striking case, such as that supplied by the discovery of the mammoth, to show clearly the fallacy of deductions which were almost universally received by scientific men not many years ago, which still occasionally mislead, and which may even now be met with in some popular hand-books of science.

ELEPHANT. An order of the E. was instituted in Denmark, by king Frederick II. The badge was a collar of elephants towered, supporting the king's arms, and having at the end the picture of the Virgin Mary.

ELEPHANT, SEA, *Macrorhinus proboscideus*, also known as the **ELEPHANT SEAL**, the **PROBOSCIS SEAL**, etc., is the largest of the seal family (*phocidae*), an inhabitant of the seas of the southern hemisphere. It is more than twice as large as an elephant, being sometimes 30 ft. in length, with a circumference of about 18 ft. at the thickest part, which is at the chest, immediately behind the fore-flippers or swimming paws; the body tapering towards the tail. The color is grayish, bluish gray, or more rarely blackish brown. The whole body is covered with very short hair, distributed in patches, giving it a spotted appearance somewhat like watered silk. The swimming paws are large and powerful; the fore-paws have five nails, the thumb-nail easily distinguishable from the others; the hind-paws have not even the rudiments of nails, but are beautifully constructed like the webbed foot of a bird, so as to expand, and increase the power of swimming. The true nail is very short, not more than 6 in. long. The head is larger in proportion than in many seals; the eyes are very large and prominent, with eyebrows of coarse hair; the whiskers are composed of very long and coarse spirally twisted hairs; there are no external ears; the canine teeth are remarkably large and massive, somewhat assuming the character of tusks. The nose of the males is very remarkable, being prolonged into a kind of proboscis of about a foot long, which, however, is not at all an organ of prehension, and, indeed, seems to serve no purpose whatever analogous to those which are served by the proboscis of the elephant, but in its ordinary state hangs flaccid on the face, becoming distended like the wattle of a turkey when the animal is roused to passion of any kind, and in particular presenting this distended appearance during the rutting season. At that season, also, the males have furious combats, the victor winning for himself a whole herd of females. When the proboscis is dilated, the voice of the sea-elephant, which usually is like the lowing of an ox, is completely changed, and becomes a loud and extraordinary gurgling.

Sea-elephants are found on Kerguelen's Land, Juan Fernandez, South Georgia, the States islands, South Shetland, the Falkland islands, etc. They migrate southwards at the beginning of summer, and northwards at the approach of winter, thus avoiding the extremes of heat and cold. A single individual sometimes yields 1400 or 1500 pounds or 70 gallons of excellent oil, on account of which these animals are pursued to an extent that seems to have already much reduced the numbers of the species. They are either shot or killed by means of long lances. Cuttle-fish and other cephalopods seem to be their principal food; but remains of marine plants have also been found in the stomach.

The skin of the sea-elephant is not at all valued on account of its fur, but its thickness and strength make it very useful for harness-making and similar purposes. The flesh is black, oily, and indigestible; the tongue (salted) alone being esteemed a delicacy. The principal product, however, is the oil, which burns slowly, with a clear flame, and without smoke or disagreeable odor. See illus., **MAMMALIA**, vol. IX.

ELEPHANTA, an island of 6 m. in circuit, stands in the harbor of Bombay (q.v.), about 7 m. to the e. of that city, and about 5 m. to the w. of the mainland. It takes this its European name from a huge figure of an elephant near its principal landing-place, which, however, appears to have gradually crumbled away. This colossal animal has been cut out of a detached rock, which is apparently of basaltic origin. Further towards the interior, three temples, dug out of the living mountain, present themselves—the roofs being supported by curiously wrought pillars of various forms and magnitudes, and the walls being thickly sculptured into all the varieties of Hindu mythology. The largest of the three excavations is nearly square, measuring 133 ft. by 130½ ft.; and immediately fronting its main entrance stands a bust or third-length of a three-headed deity, with a height of 18 ft., and a breadth of 23. These monuments of superstition, like the quadruped which guards, as it were, the approaches to them, are said to be rapidly decaying—a state of things which, besides in some measure accounting for the execution of such works, seems to be inconsistent with any very high antiquity. The island is in lat. 18° 57' n., and long. 73° east.

ELEPHANTIASIS is a term applied to two varieties of skin-disease, in which the limbs, from their enlargement, and from the changed condition of the skin, have a slight resemblance to those of the elephant. There is the *elephantiasis of the Greeks*, which is usually regarded as the same as the eastern leprosy, and as the *spedalskhed* of Norway; and the chief features of which are described in the article **LEPROSY**. In this affection, the size of the limbs and the state of the epidermis are comparatively slightly altered. In the *elephantiasis of the Arabs*, which seems to be identical with the *Barbadoes leg*, (q.v.), there is great enlargement of the affected parts, and the skin is much thickened.

ELEPHANTINÉ, a small island of the Nile, lying opposite to Assouan (q.v.), the ancient Syene, on the confines of Egypt and Nubia, in 24° 5' n. lat., and 32° 34' e. long. From this island, the Greek mercenaries were sent by Psammitichus I. to recall the Egyptian deserters, and it was garrisoned in the time of the Pharaohs, Persians, and Romans. The island was anciently called *Abu*, or the "ivory island," from its having been the entrepot of the trade in that precious material. The most important ruins are a gateway of the time of Alexander, and a small temple dedicated to Khnum, the god of the waters, and his contemplar deities, Anucis and Sate. This temple was founded by Amenophis III., and embellished by Rameses III. Another remarkable edifice is the ancient Nilometer, formerly mentioned by Strabo, and which appears to have been

built in the time of the Cæsars; and several remaining inscriptions record the heights of inundation from the time of Augustus to Severus. This island had the honor of giving a dynasty (the 5th) to Egypt, and was evidently an important place, the inscriptions on the rocks attesting the adoration paid by Sethos I., Psammitichus II., and other monarchs, to the local deities. Other interesting monuments have been found on this island: amongst which may be cited part of a calendar recording the rise of the dog-star in the reign of Thothmes III. (1445 B.C.), and numerous fragments of pottery—principally receipts in the Greek language—given by the farmers of the taxes in the reign of the Antonines. The island is at present inhabited by Nubians.—Wilkinson, *Topography of Thebes*, p. 460; Champollion, *Notice Descriptive*, p. 215; Champollion, *Lettres Érites*, pp. 111, 157, 171, 382.

ELEPHANT'S FOOT, or **HOTTENTOT'S BREAD** (*testudinaria elephantipes*), a plant of the natural order *dioscoreacea*, of which the root-stock forms a large fleshy mass, curiously truncate, or abruptly cut off at the end, so as somewhat to resemble an elephant's foot, and covered with a soft, corky, rough, and cracked bark. From this springs a climbing stem, which bears the leaves and flowers. The root-stock is used as food by the Hottentots. The plant is not unfrequently to be seen in hot-houses.

The name **ELEPHANT'S FOOT** (*elephantopus*) is also given, on account of the form of the root-leaves, to a genus of plants of the natural order *compositæ*, sub-order *corymbiferae*, one species of which (*E. scaber*) is common in elevated dry situations in all parts of India, and is used in Indian medicine in affections of the urinary organs.

ELETTA'RIA. See **CARDAMOMS**.

ELETZ. See **JELETZ**.

ELEUSINE, a genus of grasses, chiefly natives of India and other warm climates, several of which are cultivated as grains. This is especially the case with *E. corocana*, an Indian species, called natchnee and nagla ragee, also mand and murwa, which has aggregated digitate spikes finally incurved. The Thibetans make a weak sort of beer, much in use amongst them, from this grain. *E. stricta* is cultivated as a grain-crop in the same parts of the world, and is, like the former, extremely productive. The grain called tocusso in Abyssinia is also a species of this genus, *E. tocusso*.—A decoction of *E. Egyptiaca* is used in Egypt for cleansing ulcers; and a drink made from the seeds is regarded as useful in diseases of the kidneys and bladder. A decoction of *E. Indica* is also administered to infants in Demerara, to prevent or cure convulsions.

ELEUSINIAN MYSTERIES, the sacred rites with which the annual festival of Ceres was celebrated at Eleusis. Many traditions were afloat in ancient times as to the origin of this festival. Of these, the most generally accepted was to the effect that Ceres, wandering over the earth in quest of her daughter Proserpine, arrived at Eleusis, where she took rest on the *sorrowful stone* beside the well Callichorus. In return for some small acts of kindness, and to commemorate her visit, she taught Triptolemus the use of corn on the Rharian plain near the city, and instituted the mystic rites peculiarly known as hers. The outward method of the celebration of these mysteries is known with considerable accuracy of detail. Their esoteric significance is very variously interpreted. The ancients themselves generally believed that the doctrines revealed to the initiated gave them better hopes than other men enjoyed, both as to the present life and as to a future state of existence. Modern speculation has run wild in the attempt satisfactorily to explain these mysteries. As reasonable a solution as any other seems to be that of bishop Thirlwall, who finds in them "the remains of a worship which preceded the rise of the Hellenic mythology and its attendant rites, grounded on a view of nature, less fanciful, more earnest, and better fitted to awaken both philosophical thought and religious feeling." The festival itself consisted of two parts, the greater and the lesser mysteries. The less important feast, serving as a sort of preparation for the greater, was held at Agræ, on the Ilissus. The celebration of the great mysteries began at Eleusis on the 15th day of Boëdromion, the third month of the Attic year, and lasted over nine days. On the first day (called *agurmos*, the assembling), the neophytes, already initiated at the preparatory festival, met, and were instructed in their sacred duties. On the second day (called Haladé, *mystæ*, *To the sea, ye initiated!*), they purified themselves by washing in the sea. On the third day, sacrifices, comprising, among other things, the mullet-fish, and cakes made of barley from the Rharian plain, were offered with special rites. The fourth day was devoted to the procession of the sacred basket of Ceres (the Kalathion). This basket, containing pomegranates, salt, poppy-seeds, etc., and followed by bands of women carrying smaller baskets similarly filled, was drawn in a consecrated cart through the streets, amid shouts of "Hail, Ceres!" from the onlookers. The fifth day was known as the "day of the torches," and was thought to symbolize the wanderings of Ceres in quest of her daughter. On the *mystæ*, led by the "daduchus," the *torch-bearer*, walked two by two to the temple of the goddess, and seem to have spent the night there. The sixth day, called Iacchus, in honor of the son of Ceres, was the great day of the feast. On that day the statue of Iacchus was borne in pomp along the sacred way from the Ceramicus at Athens to Eleusis, where the votaries spent the night, and were initiated in the last mysteries. Till this stage of the proceedings, they had been only *mystæ*; but on the night of the sixth day they were admitted into the innermost sanctuary of the temple, and, from being allowed to behold the sacred things, became

entitled to be called "epoptæ," or "ephorî," i.e., *spectators*, or *contemplators*. They were once more purified, and repeated their original oath of secrecy with an imposing and awful ceremonial, somewhat resembling, it is believed, the forms of modern freemasonry. On the seventh day, the votaries returned to Athens with mirth and music, halting for a while on the bridge over the Cephissus, and exercising their wit and satire against the spectators. The eighth day was called *Epidauria*, and was believed to have been added to the original number of the days for the convenience of those who had been unable to attend the grand ceremonial of the sixth day. It was named in honor of *Æsculapius*, who arrived on one occasion from his native city of *Epidaurus* too late for the solemn rites, and the Athenians, unwilling to disappoint so distinguished a benefactor of mankind, added a supplementary day. On the ninth day took place the ceremony of the "*Plemochœ*," in which two earthen vessels filled with wine were turned one towards the e., and the other towards the west. The attendant priests, uttering some mystic words, then upset both vessels, and the wine so spilt was offered as a libation.

Initiation into the Eleusinian mysteries was compulsory on every freeborn Athenian; but slaves, prostitutes, and persons who had forfeited their citizenship were excluded from the rites. During the period of the festival, none of those taking part in it could be seized or arrested for any offense. *Lycurgus*, with a view to destroying distinctions of class, forbade any woman to ride to the Eleusinia in a chariot, under a penalty of 6,000 drachmæ. The mysteries were celebrated with the most scrupulous secrecy. No initiated person might reveal what he had seen under pain of death, and no uninitiated person could take part in the ceremonies under the same penalty. The priests were chosen from the sacred family of the *Eumolpidæ*, whose ancestor, *Eumolpus*, had been the special favorite of *Ceres*. The chief priest was called the "*Hierophant*," or "*Mystagogue*;" next in rank to him was the *Daduchus*, or *Torch-bearer*; after them came the "*Hiero-Ceryx*," or sacred herald, and the priest at the altar. Besides these leading ministers, there was a multitude of inferior priests and servants.

ELEUSIS, a celebrated t. in ancient Attica, stood near the northern shore of the gulf of *Salamis*, and not far from the confines of *Megaris*. It was famous as the chief seat of the worship of *Ceres*, whose mystic rites were here performed with great pomp and solemnity from the earliest authentic times till the era of *Alaric*. See **ELEUSINIAN MYSTERIES**. The temple of the goddess, designed by *Ictinus*, the architect of the *Parthenon*, was the largest sacred edifice in Greece. The site of the old Eleusis is now occupied by the little village of *Lefsina* or *Lepsina*.

ELEUTHERA, one of the Bahamas (q.v.), is, next to *New Providence*, the most populous island in the whole chain. Including its dependent *cayos* or *keys*, E. has a pop. of about 3000. It is more fertile than most of its neighbors, more especially surpassing all of them in the growth of fruit, such as the pine-apple, the orange, and the lemon.

ELEUTHERIA, was a festival of the Greeks, to commemorate their deliverance from the invader *Xerxes*, instituted after the battle of *Platæa*, 479 B.C. There was a semi-military parade, eulogies on the heroes who fell in the great battle, the sacrifice of a bull to *Jupiter* and *Mercury*, and the sprinkling of the ground with wine.

ELEUTHERIA BARK, a name not infrequently given to the bark of the *croton eleutheria*, also known as *cascarilla bark*. See **CASCARILLA**. It is called *eleutheria* (or *eleuthera*) bark, because it is chiefly gathered on the island of *Eleuthera*.

ELEVATED. Wings turned upwards are described in heraldry as *elevated*.

ELEVATION, in architectural drawing, is the representation of the flat side of a building, drawn with mathematical accuracy, but without the slightest attention to effect. In art, again, elevation is a raising of the subject beyond its ordinary character in real life. A very good instance of elevation in this sense is given by *Fairholt* in his *Dictionary of Terms in Art*, in *Rembrandt's* "*Adoration of the Shepherds*." The whole of the objects and surroundings of the infant Saviour are of the most homely description; and still the light which is represented as issuing from his person gives an elevation to the scene which takes off from it entirely the character of being commonplace or vulgar.

ELEVATION, in astronomy and geography, means generally the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator, and is always equal to the latitude of the place. The elevation of a star, or any other point, is similarly its height above the horizon, and is a maximum when the star is on the meridian.

ELEVATION OF THE HOST (see *Host*). Members of the church of Rome worship the host under the assumption that the bread and wine in the Lord's supper are transubstantiated into the real body, blood, and divinity of Christ, who is, on each celebration of the sacrament, offered up anew as a victim (*hostia*) by the priests. The council of Trent, having determined that upon consecration the bread and wine of the sacrament are changed into the body of the Lord Jesus Christ, true God and true man, gave this decision: "There is, therefore, no room to doubt that all the faithful in Christ are bound to venerate this most holy sacrament, and to render thereto the worship of *latria*, which is due to the true God according to the constant usage of the Catholic

church." In conformity with this decision, the rubric of the missal says: "Having uttered the words of consecration, the priest immediately, falling on his knees, adores the consecrated host; he rises, shows it to the people, places it on the corporale, and again adores it." Rising up after he has adored it, he elevates it before the people, who, as soon as they see it (having notice also by the ringing of the bell), fall down in humble adoration to it as if it were God himself. They pray to it, and use the same acts of invocation as they use to Christ. The host is also elevated for worship when it is carried through the streets in solemn procession, on its way to the dwellings of the sick, or on the feast of Corpus Christi, or before the pope. The custom of thus elevating the host was introduced into the church of Rome in 1216, the year after transubstantiation was made an article of faith. Pope Honorius then ordered that the priests, at a certain point of the mass service, should lift up the host and cause the people to prostrate themselves in worshipping it.

ELEVATOR, a mechanical contrivance for raising goods or passengers from a lower story of a building to a higher. The most usual form of E. consists of a car or an open platform, the former being used for passengers and the latter for goods, which is moved up and down a vertical square well or shaft, called the elevator shaft, by mechanism set in motion either by steam or hydraulic power. Elevators of this kind are very frequent in hotels and warehouses. A grain elevator is a very different contrivance, used in grain mills and storehouses for discharging the grain from vessels and lifting it from one floor to another: it consists sometimes of a series of boxes or buckets attached to a belt traveling round two drums, one above and one below; sometimes of a rotating archimedeian screw which draws the grain along channels or pipes either vertical or inclined. In this country a grain elevator, by a misuse of words, has grown to mean a building in which grain is handled and stored.

With the increasing growth of high office buildings and stores, elevators are now in almost universal use in such buildings, which frequently rise to 20 or 25 stories. For such heights as these, high speed elevators have become necessary, and in some buildings as many as 15 or more passenger elevators are in constant use. The two most approved types of elevators are the hydraulic and the electric, which have almost entirely superseded the steam elevator, or those in which the steam engine acts directly upon the elevator cables. The chief advantages of the hydraulic and electric elevators is their safety and easy control by the operator when running at high speed. The hydraulic elevator is operated by a long water cylinder in which a piston or plunger is raised by water pumped into the cylinder. The piston rod is connected by means of multiplying sheaves to the car so that for one foot of motion of the piston the car moves several feet. The speed of the car is regulated by the rate at which the water is admitted or discharged from the cylinder.

Electric elevators are of several kinds. In the simplest kind the electric elevator turns a drum on which the elevator cable is wound. In a more recent, and perhaps the safest form of elevator, the sheaves are carried by a large nut, which travels back and forth on a long screw. The screw may be 20 or 30 feet long and is revolved by an electric motor directly connected to one end of it. The motor is started, stopped, and varied in speed by a switch placed in the elevator car.

Safety attachments of some kind are always provided to prevent the car from falling in case of a break in any part of the mechanism. These are very numerous in design, but in general consist of some kind of a governor which, when the cable breaks or the car descends faster than a determined speed, releases two catches on either side of the car, which take hold of toothed racks on either side of the shaft and prevent the car from falling.

ELEVENTH, in music, is the interval of the octave above the fourth.

ELF, a fairy, pl. **ELVES**. See **FAIRIES**.

ELF-ARROW-HEADS, **ELFIN-ARROWS**, **ELF-BOLTS**, **ELF-DARTS**, **ELF-SHOT**, and **ELF-STONES**, names popularly given in the British islands to the arrow-heads of flint which were in use at an early period among the barbarous tribes of this country and of Europe generally, as they are still in use among the American Indians, the Esquimaux of the Arctic regions, and the inhabitants of some of the islands in the Pacific ocean. It was believed that elves or fairies, hovering in the air, shot these barbs of flint at cattle, and occasionally even at men. Thus, Robert Gordon, of Straloch, an accomplished country gentleman of the n. of Scotland, writing in 1654, tells how one of his friends, traveling on horseback, found an elf-arrow-head in the top of his boot, and how a gentlewoman of his acquaintance, when out riding, discovered one in the breast of her habit. He remarks that, although they are got by chance in the fields and on the highways, one who goes to look for them on purpose will search in vain. He adds that they are most commonly met with after showers—a circumstance which probably helped them in Germany to their names of "thunder-bolts" and "thunder-stones," and is easily enough explained. The rain, by washing away the earth in which they have been imbedded, makes them more readily perceptible to the eye, especially if the sunshine happens to fall upon them. Cattle dying suddenly in the fields were believed to have been struck by elf-arrows—a belief which yet lingers in Ireland, and perhaps in some secluded parts of Scotland. "Thus, when cattle are sick," writes Mr. W. R. Wilde, in his *Catalogue of the Antiquities in the Museum of the Royal Irish Academy* (Dub. 1857), "and the cattle doctor, or fairy doctor, is sent for, he says the beast has been 'elf-shot,' or stricken

by fairy or elfin darts; and he forthwith proceeds to feel the animal all over; and, by some legerdemain, contrives to find in its skin one or more poisonous weapons, which, with some coins, are then placed in the water which is given it to drink; and so a cure is said to be effected." The elf-arrow-head was occasionally set in silver, so as to be worn on the person as a talisman, or had a hole drilled through it, so that it might be dipped in water, which, being thus endowed with healing virtue, was used sometimes as a wash, more commonly as a draught. See FLINT IMPLEMENTS AND WEAPONS.

EL-GHOR, "*the valley*," is, according to Robinson (*Phys. Geog.*, p. 73), the name now given to the northern part of the great depression which extends from the base of Mt. Hermon to the Red sea. The southern part retains the old Hebrew name, El-Arabah (q.v.), the boundary between the two being the range of chalk cliffs about 6 m. s. of the Dead sea. The length of El-Ghor, from the sea of Galilee to the Dead sea, is about 65 m., and between these points there is an average descent of over 10 ft. to a mile. The width of the valley varies from about 6 m. at the northern end to 10 or 12 in the neighborhood of Jericho. On the w. is a series of irregular and precipitous cliffs from 800 to 1200 ft. high, everywhere naked and desolate; on the e. the mountains are still higher. About 22 m. s. of the sea of Galilee the ridge Kum Surtabeh, crossing the valley obliquely, divides it into the upper and lower Ghor. At this point there is a sudden "breakdown" in the bed of the Jordan. Above it the valley is generally well watered and fertile; below, it becomes dry and desolate, being covered with a white nitrous crust. Within the general valley of El-Ghor there is a still lower depression, varying from a quarter to a half of a mile in width, through which the Jordan (q.v.) flows.

ELGIN, a co. in the province of Ontario, Canada, on lake Erie and Thames river; intersected by the London and Port Stanley railroad; 725 sq. m.; pop. '91, 42,109. The co. town is St. Thomas.

ELGIN, a city in Kane co., Ill., on Fox river, the Chicago, Milwaukee, and St. Paul, and the Chicago and Northwestern railroads; 36 m. w. of Chicago. The city is on both sides of the river, which affords abundance of water-power. The Elgin National Watch company is the most important manufacturing establishment. The city is the centre of a fine agricultural region, and has large sales of butter and cheese. E. has a high school, Elgin academy, St. Mary's academy, graded system of public schools, the Illinois Northern Hospital for the Insane, Sherman hospital, Gail Borden public library, Lord's, Highland, and Gifford parks, electric lights and street railroads, improved water works, several banks, numerous churches, and daily and weekly newspapers. Besides watches, butter, and cheese, the principal industries are the manufacture of sewing-machines, bicycles, shoes, silver-plated ware, and lumber. Pop. '90, 17,823; estimated in '97 to be 22,000.

ELGIN, a royal burgh, the co. t. of Elgin or Morayshire, and a station on the Inverness and Aberdeen Junction railway, situated on the right bank of the river Lossie, about 5 m. from the sea. Pop. '91, 7799. E. joins with Banff, Peterhead, Inverurie, Cullen, and Kintore, in returning a member to parliament. It was probably a royal burgh so early as the reign of King David I. (1124-53), and had its privileges confirmed by several of his successors. E. is chiefly remarkable for the beauty of its situation, lying placidly in a gentle curve of the Lossie, for the salubrity of its climate, and for its history as the see of the bishop of Moray. The old town was partially burned in 1390 by the notorious Wolf of Badenoch (Alexander Stewart, earl of Buchan); in 1402 by Alexander, the son of the lord of the Isles; and in 1452 by the earl of Huntly—this last calamity originating the proverb, "Half done, as Elgin was burned." Its once magnificent cathedral church, partly of early English and partly of middle-pointed architecture, dedicated to the Holy Trinity, was begun by bishop Andrew Moray in 1224, on the transference of the see from Spynie; was injured by fire in 1270; was nearly burned down by the Wolf of Badenoch in 1390; was restored under bishops Bur, Spynie, Innes, and Leighton (1390-1424); and from subsequent accident and dilapidation is now a mere ruin. The other religious buildings of the olden time were the church of St. Giles, a picturesque example of our old parish churches, replaced 1826-28 by the modern less interesting structure; the monastery of the Black Friars, long since demolished; the convent of the Gray Friars, the walls of whose church remain; the hospital of the Maison Dieu, on the site of which is Anderson's institution; the Leper house, still commemorated by the grounds called the Leper lands; and the chapel of St. Mary of the castle, which gave name to the Lady hill and Lady well on the w. of the town. The castle itself, styled of old the manor of Elgin, whose ruins, surmounted by an obelisk—erected to the memory of George, fifth and last duke of Gordon—crowned the Lady hill, was a residence of the earls of Moray, for some time superiors of the burgh.

ELGIN, THOMAS BRUCE, Earl of, 1766-1841; the seventh of the line, succeeding his brother in the earldoms of Elgin and Kincardine when but seven years old. He received his education at Harrow and Westminster, and, later, at the university of St. Andrews and at Paris where he studied international law and in Germany where he devoted his time to military studies. He then entered the army and rose to be general; was envoy at Brussels, at Berlin, and at Constantinople from 1799 to 1802. While at the latter place he secured and removed from Athens the sculptures known as the "Elgin marbles," now in the British museum. (See ELGIN MARBLES.) Lord Elgin was a representative peer of Scotland for more than 50 years.

ELGIN AND KINCARDINE, Earl of, Governor-General of India, James Bruce, eighth earl of E., was b. in Park Lane, London, in 1811. He was educated at his father's seat, in Fifeshire, and afterwards went to Christ Church, Oxford, where he was first-class in classics, 1832; became fellow of Merton, and graduated M.A., 1835. He

entered public life in 1841, when, as lord Bruce, he was returned at the general election on the conservative interest for Southampton. A petition was presented against the return, and the election was declared void. Before, however, a new writ could issue, lord Bruce had succeeded his father (who enriched the British museum by the invaluable collection of sculpture known as the "Elgin marbles," q. v.) as earl of Elgin. Those who remember his early parliamentary and pre-colonial career, state that he gave early promise of oratorical distinction, and assert that if he had thrown himself into the politics of the day, he would have taken a high position as a parliamentary debater. By succeeding to a Scotch peerage, however, he was, in his own words, "expelled from the house of commons without being admitted into the house of peers." Being offered the governorship of Jamaica, in Mar., 1842, by the earl of Derby—then lord Stanley—he went to Jamaica, where he administered the affairs of the island with so much ability and success, that in Aug., 1846, the governor-generalship of Canada was tendered to him by earl Grey, then secretary of state for the colonies in the administration of lord J. Russell. Lord E., still finding himself in the same position as a Scottish peer, accepted the office, and went to Canada. His administration of the government of Canada will ever be a bright spot in our colonial history, and a model to future governors of English dependencies. He found Canada governed by cliques, and torn by intestine feuds. With admirable tact and entire success, he inaugurated a system of self-government, which has rendered the provinces of British America a support to the British throne, in place of being a source of weakness. Under his government, Canada made such strides in importance and prosperity, that between 1847 (in the beginning of which year he entered upon his government) and 1855, when he returned to England, the revenue of that great British possession quadrupled itself. During his administration, he successfully negotiated a treaty for reciprocity of trade between British America and the United States, which admitted the whole produce of British North America to be brought into competition with the products of the United States in their own markets. This treaty, till it was renounced by the United States in 1866, put an end to the risk of collision as to the fisheries between this country and America, which lord E. described as the most serious risk which had presented itself during his public service. His popularity was great, not only in Canada but the adjacent states, the citizens of which offered him ovations. He was now a peer of the United Kingdom (having been summoned to the house of lords in 1849), and was appointed lord-lieutenant of Pifeshire. In 1857, the affair of the *lorcha Arrow*, and the bombardment of Canton, by sir John Bowring, led lord Palmerston to invite lord E. to go to China as plenipotentiary extraordinary. An army was equipped to carry out the policy prescribed by the British government, and he started on his mission. But before he could approach his destination, and when he had barely left England a month, the Indian mutiny broke out. Lord E. did not hesitate a moment in preferring the safety of India to the success of his Chinese negotiations. He dispatched the Chinese expedition to lord Canning's assistance, and the English in India were thus enabled to hold their ground until further reinforcements arrived. After thus consigning himself to an inaction of several months, lord E. proceeded to China, and in 1858, in conjunction with baron Gros, the French plenipotentiary, he negotiated the treaty of Tientsin, which promised to give Great Britain a freer access to China than she had ever enjoyed before. He found time, before his return, to negotiate a treaty with Japan, under which English manufactures are admitted at low rates of duty, and a British minister is permitted to reside at Jeddo. On his return home, he was appointed postmaster-general. He had scarcely time to become acquainted with his duties, before the treachery of the Chinese, in firing upon the British squadron from the Taku forts, led to the organization of another Chinese expedition, and to lord E.'s second mission to China. A combined English and French force penetrated to the capital, and enabled lord E. and baron Gros to dictate a peace under the walls of Peking. On the expiration of viscount Canning's term of service, the governor-generalship of India was offered by lord Palmerston to lord E. (1861), and accepted by him. He died in India, Nov., 1863. Lord E. (who was the representative in the male line of the great Scottish house of Bruce) was twice married: in 1841, to the daughter of Mr. Cumming Bruce, M.P. (she died 1843); and in 1846, to the daughter of the first earl of Durham, by whom he had a son, Victor Alexander, ninth earl, born 1849, and appointed viceroy of India in 1893. Lord E. was K. T. (1847), privy councilor (1857), G.C.B., civil, extra (1858).

ELGIN MARBLES, a celebrated collection of ancient sculptures, brought from Greece by Thomas, seventh earl of Elgin, and acquired from him for the British Museum in 1816, at the sum of £35,000.

These sculptures adorned certain buildings on the Acropolis of Athens; the chief portions, which are from the Parthenon or temple of Minerva, were designed by Phidias, and executed by him, or under his superintendence. They consist of—1. Portions of several of the statues that were placed in the e. and w. tympana or pediments, the most important of which are the Theseus or Hercules, Ilissus or river-god, upper portions of the torsos of Neptune and Minerva, Iris, torso of Cecrops, Ceres, and Proserpine, the Fates, heads of the horses of Hyperion, and one of the horses of Night. Of all these, the Theseus, and the head of the horse of Night, are the most perfect, the former wanting only the hands and feet and part of the nose, while even the surface of the latter is

very little injured. But however mutilated, the greatness in style of these magnificent works is clearly manifest, and from the merest fragment valuable instruction in art may be obtained. 2. Fifteen metopes, executed in high relief, representing the battle of the Centaurs and Lapithæ. A metope is the interval between the triglyphs on a Doric frieze—in the Parthenon there were 92, 14 on each front, and 32 on each flank of the temple—and on every metope, a Centaur engaged in conflict with one of the Lapithæ is represented in a style of the highest excellence in point of spirit and truthfulness. 3. A large portion of the frieze of the outer walls of the cella. This remarkable work represents the solemn procession to the temple of Minerva during the Panathenic festival, and has never been equalled for elegance of composition and the variety and gracefulness of the figures. It is executed in low relief, in order to adapt it to the light, for placed within the colonnade, it received its light between the columns, and by reflection, from the pavement below. This exquisite frieze occupied, slab after slab, a space of 524 ft. in length. The remains of it in the British museum on slabs and fragments of marble are to the extent of upwards of 249 ft., besides 76 ft. in plaster casts.

Although the Elgin marbles are now acknowledged to be the most precious collection existing of specimens of Greek art in its purest state, yet it was only after very considerable hesitation that government consented to purchase them, and then the sum awarded was not only far short of anything like a fair value, if indeed a value could be put on such treasures, but lord Elgin was left largely out of pocket after all his exertions. Again, from petty jealousy, some of the connoisseurs of the day, who had earned a sort of reputation from their collections—of whom Mr. Payne Knight may stand for the type—made strong efforts to underrate these great works; while others, like lord Byron, from feelings apparently generous, but quite mistaken, because not based on fact, heaped obloquy on lord Elgin, and opposed their acquisition. But it has been clearly proved that lord Elgin, so far from destroying, has saved these masterpieces from destruction. It was not to be expected but that foreigners would grudge this country such an acquisition, but certainly it is remarkable that such opinions should have been expressed in this country. The view adopted by a foreigner, who has devoted much attention to the subject, M. Viardot, author of *Les Musées d'Europe*, may be accepted as that generally taken abroad; and it is very different from that at one time so pertinaciously maintained by many in England. M. Viardot remarks: "It is said that, to justify the appropriation of the Lahore diamond, the English allege that if they have taken it, it was merely to prevent its appropriation by others. They may give the same excuse for their appropriation of the marbles of the Parthenon. No doubt, lord Elgin has carried them off; and the Greeks of the present day, seeing the old temple of their Acropolis despoiled of all its ornaments, have a good right to curse the spoiler. But when we think of the devastation these works have so often experienced, the total destruction of the principal statues, and the shameful mutilation of the others, and the risk these last ran of being entirely destroyed in their turn—when we consider that these precious relics of art are conserved in a place of surety, and placed in the center of artistic Europe, one loses the desire and almost the right to charge the English with piracy and robbery. For my part, if, in the course of my long devotion to the marbles of Phidias, a regret has come to trouble the ardent pleasure of my admiration, it was, that the robber of these marbles was not a Frenchman, and their resting-place the museum of Paris."—In 1891 an agitation was begun in London in favor of returning the Elgin marbles to Greece, but, though many newspaper and magazine articles advocated this restoration, the movement came to nothing. See *illus., SCULPTURE*, vol. XIII.

ELGINSHIRE, **MO'RAYSHIRE**, or **MURRAYSHIRE**, a maritime co. in the n.e. of Scotland, on the Moray firth. It contains 476 sq.m., and is 30 m. long and 20 m. broad. About a third part was formerly cut off on the s. by a detached part of Inverness-shire; but by an act of parliament, passed in 1870, this part was annexed to Inverness-shire, and a part of the intervening portion of Inverness-shire, of about the same extent, rental, and population, was annexed to Elginshire. In the s. are the high rugged Monadhliadh mountains of Inverness-shire, dividing the basins of the Spey and Findhorn, and forking in the n. to include the basin of the Lossie. In the s., gneiss predominates, with a little granite; and in the n., sandstone with fish and reptilian remains, and small patches of oolitic and Wealden strata. West of the Findhorn mouth are the sand-dunes of Culbin, 3 sq.m. in extent, some of them rising 118 feet. Great masses of peat and trunks of trees are often cast ashore near the mouth of the Findhorn. The climate is mild and dry, and the co. has been called the Devonshire of Scotland, the mountains of Aberdeenshire and Banffshire protecting it from the cold moist winds of the German ocean. The soil is open, sandy, and gravelly, and very fertile in the n., with some deep loams and clays. Pop. '81, 43,788; '91, 43,471.

ELI, the high-priest of Israel in the latter part of the period during which the ark of the covenant remained at Shiloh. That he was of the family of Ithamar, the youngest son of Aaron, is shown by comparing several passages of Scripture. He was probably the first high-priest in that branch of Aaron's family. His sons having died before him, the office passed to his grandson, Ahitub, and continued in his family until Solomon removed Abiathar and made Zadoc, a descendant of Eleazar, high-priest. Eli was also

judge over Israel for a period of 40 years, beginning, probably, soon after the death of Samson, and extending to his own death. If his languid reproofs of the wickedness of his sons were fair specimens of his general administration, he must have been a very inefficient magistrate. The divine judgment came at length on his house for the iniquity which he knew was practiced but did not strive to arrest. His sons made themselves vile, and he restrained them not. The sentence against them, pronounced first by a prophet and afterwards by the child Samuel, was executed in a battle with the Philistines, during which the ark of God was taken and the dissolute priests were slain. When Eli, then 98 years old, heard the news, he fell backward from his seat and died.

ELIA. See LAMB, CHARLES.

ELI'AS, ST., a lofty mountain which occupies a conspicuous position on the n.w. coast of America, in lat. 60° 18' n., and in long. 140° 30' west. Various authorities have estimated its height at from 12,661 to 19,500 feet, and it is estimated by the U. S. Coast and Geodetic survey to be 18,100. It is on the boundary between Alaska and the Dominion of Canada. Its ascent has been a matter of great difficulty, owing to the fact that the snow line descends to 2,000 or 3,000 feet above sea-level, but attempts to reach the summit have been made, among the most noteworthy of which was that of Prince Louis of Savoy, on July 31, 1897.

ELIAS LEVITA, 1472-1549; b. Bavaria; the most distinguished Hebraist of his time. Banished because he was a Jew, he went to Italy early in the 16th c., taught Hebrew at Venice and Padua, and lectured and wrote on Hebrew grammar. In 1512, he went to Rome, where he was so friendly with high dignitaries of the church, that he was accused of apostasy. His latest years were spent in Venice. He was the author of many works, of which the most valuable are those in Hebrew philology.

ÉLIE DE BEAUMONT, JEAN BAPTISTE ARMAND LOUIS LÉONCE; 1798-1874; b. France; professor of geology in the Paris school of mines; in 1833, engineer in chief of the mines of France; senator of France in 1852, and on the death of Arago chosen perpetual secretary of the academy of sciences. His best service to science was in connection with the geological map of France, on which he was employed for 18 years.

ELIGIUS, better known as **ST. ELOI**, or **ELOYSIUS**, one of the most illustrious names in the ecclesiastical history of France, was born near Limoges, about 588 A.D. He early manifested a taste for designing, and was placed by his parents with the master of the mint at Limoges, where he learned the goldsmith's trade, and became the most celebrated artist of his time. He was coiner to Clotaire II. of France, and later, to his son and successor, Dagobert I., who also made him his principal minister. Both kings employed him with important works, among which were two chairs of gold, adorned with jewels, which at that time were reckoned *chefs-d'œuvre*, also many ornaments for churches and tombs. But, although amassing great wealth, he acquired great distaste for it, and devoted much of it to deeds of piety, especially to the redemption of slaves, of whom it is said he sometimes emancipated a hundred at once. From his high position at court he was able to use much influence over the king in obtaining large donations for founding hospitals, churches, and monasteries. In 640 he was made bishop of Noyon, and held the office eighteen years. He died in 659. See Neander, *Light in Dark Places*.

ELIJAH (in the Greek form, occurring in the New Testament, Elias), the greatest of the prophets of Israel, was born at Tishbe, in Gilead, on the borders of the desert. He comes upon the scene in the time of Ahab, about 920 B.C. When that monarch, to please his Phœnician wife Jezebel, had introduced, on an extensive scale, the worship of Baal, E. pronounced a curse on the *land*. The prophet had to flee. He took refuge by the brook Cherith, probably one of the torrents that cleave the high table-land of his native region. Here he was miraculously fed by ravens. He then went to Zarephath, a town lying between Tyre and Sidon. Here he lodged with a widow woman, prolonged her oil and meal, and brought back her son to health from the brink of the grave. Subsequently, he made a temporary reconciliation with Ahab, and on Mt. Carmel executed dreadful vengeance on the prophets of Baal, slaying 400 with his own hand. Such a deed enraged Jezebel to the utmost. She swore to destroy the prophet, who once more took refuge in flight. He rested not till he reached Beersheba in the far south, on the edge of the desert that leads down to Sinai. The brief allusion in Scripture to his weary wanderings is very touching. At last he comes to Horeb, where he has an interview with Jehovah. The passage in which this is recorded is one of the grandest and most significant in the whole of the Old Testament. He then receives certain instructions from Jehovah, among others that he should select Elisha to be prophet in his room. E.'s next appearance is when Ahab rides forth to take possession of Naboth's vineyard: he denounces the murderous monarch, and utters an awful prophetic curse on him and his wife. After the death of Ahab, he rebukes the idolatries of his son Ahaziah in a solemn and bloody fashion; and after the death of Ahaziah, we find him interfering in the affairs of the king of Judah, who had married a daughter of Ahab, and had begun to "walk in the ways of the kings of Israel." He denounced his evil doings, and predicted his death. The closing scene of his life on earth is exquisitely narrated. A chariot of fire and horses of fire appeared after Elisha, and he had crossed the Jordan, and "Elijah went up by a whirlwind into heaven."

ELIMINATION is a process by which, where we have a number of statements concerning several quantities, we can obtain a separate statement concerning each. Thus, in algebra, elimination is the operation which consists in getting rid of a quantity or letter which is common, say, to two equations, by forming out of the two a new equation, in such a way as to make the quantity in question disappear. If three unknown quantities, for instance, are to be found from three independent equations, the first step is to form out of the three given equations two new equations, so as to eliminate one of the unknown quantities; from these two equations another of the quantities is eliminated in the same way, giving one equation with one unknown quantity, the value of which is then found. In complicated equations, elimination becomes difficult, and often impossible. Elimination is an important process in other sorts of reasoning besides the mathematical; in this larger acceptation, it means the setting aside of all extraneous considerations—of everything not essential to the result. In astronomical observations, the elimination of errors of observation is often effected by repeating the observations several times in such a way as to cause the errors to be of opposites kinds, then adding the observed values, and taking their average.—The word to “eliminate” is often erroneously used in the sense of to “elicit,” or bring to light.

ELIOT, CHARLES WILLIAM, LL.D., b. Boston, 1834; a graduate of Harvard, and tutor of mathematics in that institution. In 1858, he became interested in chemistry, and went to Europe to study that branch of science. In 1865, he was appointed professor of chemistry and metallurgy in the Massachusetts institute of technology; in 1869, he succeeded Thomas Hill as president of Harvard university. His father, **SAMUEL ATKINS ELIOT**, was the author of a history of Harvard, and for nearly a dozen years treasurer of the college. Dr. E. has led in the introduction of extensive changes in the course of study and the administration of his college, tending towards the style of the European universities.

ELIOT, GEORGE. See **EVANS, MARIAN.**

ELIOT, JARED, 1685–1763 ; b Conn.; grandson of the “apostle to the Indians,” preacher, agriculturist, and botanist; also eminent as a physician. He brought the white mulberry-tree to Connecticut. Among his works were *Agricultural Essays*, and *Religion Supported by Reason and Revelation*.

ELIOT, Sir JOHN, 1592–1632 ; an English statesman, b. at his father's seat on the river Tamar. He graduated at Oxford, studied law, and traveled on the continent, for part of the time with George Villiers, afterwards duke of Buckingham. At the age of 22, he entered parliament, and at 27, was made vice-admiral of Devon, in which office he captured the famous Nutt, a pirate whose depredations were a constant affliction upon the commerce on the southern coast. But by corrupt influences at court, Nutt was released to continue his depredations, while E. was imprisoned, on false charges, in the Marshalsea for about four months. Immediately upon his release, in 1624, he was returned to parliament, where, during the first three parliaments of Charles I., with Pym, Hampden, Selden, and Coke, E. was the foremost leader in resistance to the encroachments of the crown, surpassing all the great statesmen of his time in his symmetrical union of learning, genius, and lofty devotion, with absolute personal bravery and the fire of oratory. He spoke out boldly against the lawlessness and venality of the ministry, and the weak, ill-tempered foreign policy of Buckingham, and urged parliament to withhold supplies until an account was given of the money already voted. For comparing Buckingham to Sejanus, he was imprisoned in the Tower in 1626; but the commons compelled his release, and exonerated him by special vote. He suffered another short imprisonment for petitioning the king against forced loans, and later received sentence of outlawry. These persecutions only increased his popularity, and though earnestly opposed by the court, he was again returned to parliament in 1628. He took part in drawing up the petition of right, and, on the last day of that parliament, read a protest against tonnage and poundage and other taxes unauthorized by parliament; and against the king's illegal encouragement of Arminians and Roman Catholics. Being summoned before the council, with Holles, Selden, Valentine, and others, he refused to answer for his acts in parliament except to parliament itself. He was then rigorously confined in the Tower, with his fellow-members, for more than two months, until manifestations of popular indignation compelled the king to bring him to trial. During tedious delays his confinement was somewhat softened; he occupied himself in writing a personal defense, and other works; and in Feb., 1631, sentence was at last given. All the prisoners were condemned to a fine, the largest, of £2,000, being imposed upon E.; to imprisonment during the king's pleasure; and not to be released until they had given security for good behavior, submitted to the king, and acknowledged their offenses. The confinement of the others was gradually relaxed, until they were all released, but E. would make no submission. Dec. 21, 1631, more than a year after his arrest, the council resolved to force him to submission. They removed him to a cold, unwholesome room, and forbade any one except his sons to visit him. His health broke down, and with medical advice he petitioned the king, in simple, manly words, for such release as health demanded. His petition was refused as not sufficiently humble. In a second petition he declared himself “heartily sorry that he had displeased his majesty,” but added no words acknowledging wrong. He was denied an answer. He

had now been prisoner two years, and though only forty years old, was worn out with cruel confinement. He died two weeks after the king refused his last petition. Charles even refused permission to his sons to bury him in the family tomb, and ordered that he should be buried in the church of the parish where he died. During the commonwealth his sentence of conviction was reversed by act of parliament.

ELIOT, JOHN, 1604-90; "the apostle of the Indians;" b. at Nasing, Essex, Eng. He graduated at Cambridge in 1623, and entering the non-conformist ministry, emigrated in 1631 to Boston, Mass., where he officiated for a year in the church of Mr. Wilson, who was then in England, and, in 1632, he was settled over the church in Roxbury. He soon began preaching to the Indians, acquiring their language by the help of a young Pequot, taken prisoner in 1637. He translated the commandments, the Lord's prayer, and many texts, and first preached without an interpreter in 1646, at Nonantum, now Brighton, on the border of Newton. A settlement of Christian Indians was established, and a missionary society was organized in England, of which Robert Boyle was a leading member. This society sent Eliot £50 per annum to supplement his salary of £60 at Roxbury. In 1651, the settlement was removed to Natick, where an Indian church was formed in 1660. In 1653, E. published a catechism for their use, said to have been the first work published in the Indian language; no copy is known to exist. In the same year accounts of Eliot's labors were published by the corporation in London, and in 1655, a tract containing the doctrinal and experimental confession of these Indians who had been baptized and admitted to church fellowship. In 1660, E. published in London *The Christian Commonwealth, or the Civil Policy of the rising Kingdom of Jesus Christ*, which was criticised as containing seditious principles. The governor and council of Massachusetts required him to retract some of its utterances. About this time he completed his great work, the translation of the Bible into the Indian tongue. The New Testament was published at Cambridge, Mass., in 1661, the Old in 1663. A second edition of the New Testament was printed in 1680, and of the Old in 1685. Both of these editions are now very rare; the language in which it was written has ceased to be spoken, and only one or two persons in recent times are able to read it. E. was assisted in the translation by the Rev. John Cotton, of Plymouth, Mass. A new edition was printed at Boston, 1822. E. published many other works in the Indian and in the English tongue. His well-known *Indian Grammar Begun*, printed at Cambridge, Mass., 1666 (reprinted 1822), has at the end these memorable words: "Prayers and pains, through faith in Jesus Christ, will do anything." Of his *Indian Primer* (1669), the only complete copy known to exist is preserved in the library of the university of Edinburgh. It was reprinted, 1877. In 1671, E. printed in English, at Cambridge, *Indian Dialogues, etc.*; and in 1672, *The Logick Primer*. Of the former the only known copy is in a private library in New York; of the latter work there is a copy in the British museum, and another in the Bodleian library. Even in his old age the pen of E. was not idle. He died at Roxbury, Mass., at the age of 86, having won all hearts by his simplicity of life and manners, and his evangelical sweetness of temper, whether in the villages of the English colonists, or in the huts and wigwams of the Indians. His Indian publications are still of value for the light which they throw upon the structure and character of unwritten dialects.

ELIOT, SAMUEL, LL.D., b. Boston, 1821; graduated at Harvard, and traveled in Europe four years. He became professor of history and political science in Trinity college, Hartford, in 1856, and was president from 1860 to 1866; and in 1874, professor of political science and constitutional law in the same institution. He has published *Passages from the History of Liberty*, 1847, in which he traced the careers of Savonarola and other reformers, a work afterwards enlarged under the title *The Liberty of Rome*, 1849, and republished, with additional volumes, as *The History of Liberty*, 1853. He also published a *Manual of United States History*, 1856.

ELLIOTT, OR ELIOT, GEORGE AUGUSTUS. See **HEATHFIELD, LORD**.

ELIS, one of the ancient divisions of the Peloponnesus, bounded n. and n.e. by Achaia, e. and s. by Arcadia, and w. by the Ionian sea. It was originally divided into three districts—Cœle or Hollow Elis, Pisatis, and Triphylia. Of these, the first-named was by far the largest and most valuable, comprising as it did the broad and fertile plains watered by the Peneus and the Ladon, and producing excellent crops of corn, cotton, and flax; while the pastures by the river-banks reared cattle and horses of proverbial excellence. This district, from its fertility, was called "the milk-cow of the Morea." Pisatis is drained by the Alpheus, and is separated from Cœle Elis by Mt. Pholoë, a spur of Erymanthus. The low grounds of this division possess great natural fertility. Most of the surface of Triphylia is hilly, being occupied with offshoots from the great Arcadian ranges. It is separated from Pisatis by the Alpheus, on whose banks were the grove and temple of Olympic Jove, and the plain in which the great Olympic games were celebrated. Though E. had few facilities for preventing invasion, it yet suffered less from war than any other of the Greek states—an advantage chiefly due to the sacred character of the country, as the seat of the greatest of the national festivals. Their prerogative of holding the Olympic games gave the Eleans a prestige which they continued to enjoy in greater or less degree till the games themselves were suppressed by the emperor Theodosius in 394 A.D.—**ELIS**, now *Kaloskopi*, the capital of the fore-

going country, stood on the Peneus, and was long famous as one of the most splendid and populous cities of Greece. It was at one time strongly fortified, and contained many magnificent buildings, conspicuous among which was the gymnasium, in which it was necessary that all athletes intending to take part in the Olympic games should go through a month's training before they were allowed to compete. See Leake's *Morea*, and Curtius' *Peloponnesus*.

ELISHA, a prophet of Israel, the successor of Elijah, who found him at the plow, and consecrated him to the sacred office by throwing his mantle over his shoulders. He exercised his functions for a period of 55 years. When Elijah was carried up into heaven, E. returned to Jericho, where he dwelt for some time. He then proceeded to Bethel, where the perplexing miracle occurred of the destruction of the 42 children by the two she-bears. After this period, he seems, besides performing an extraordinary number of miracles, to have taken an active part in the religious politics of his country, but he exhibited nothing of the fiery and sanguinary zeal of his master. Mild, tolerant, conciliatory, we hardly ever, if at all, find him rebuking the Baal-worship that was still prevalent in Israel. Many of the incidents in his history recall the creations of eastern fancy, such, for example, as those of the horses and chariots of fire round about E. on the hillside, of the smiting of the Syrian host with blindness, so that the prophet led them all unconsciously into Samaria, captive, etc. With Elijah, it has been said (see Smith's *Dictionary of the Bible*: art. "Elisha"), the miracles are "introduced as means towards great ends, and are kept in the most complete subordination thereto. But with E., as he is pictured in the Hebrew narrative, the case is completely reversed; with him, the miracles are everything, the prophet's work nothing. The man who was for years the intimate companion of Elijah, on whom Elijah's mantle descended, and who was gifted with a double portion of his spirit, appears in the Old Testament chiefly as a worker of prodigies, a predictor of future events, a revealer of secrets, and things happening out of sight or at a distance." The difficulties that thus beset the literal acceptance of the narrative of E.'s miracles have been felt by most modern commentators, and to evade these difficulties various methods, more or less satisfactory, have been employed. For several years E. was the chief theocratical counselor of Jehoram. Under the reign of Jehu and his successors, he gradually withdrew from public affairs, and died in Samaria in the reign of Jehoash, grandson of Jehu (about 840 B.C.). It has been customary to draw a parallel between E. and Christ; and his mildness and gentleness—always excepting the story of the destruction of the children at Bethel, which has perplexed all humane readers of Scripture—seem to justify this. E. is canonized in the Greek church; his day is the 14th of June.

ELIXIR (Lat. *elicare*, to extract by boiling), a term in pharmacy, which has come down from the days of alchemy, and is applied to various preparations, consisting mostly of solutions of aromatic and bitter vegetable substances in spirits of wine. The term tincture is now more common. **ELIXIR OF VITRIOL**, or aromatic sulphuric acid, is prepared from $1\frac{1}{2}$ fluid ozs. of sulphuric acid (oil of vitriol), 10 fluid ozs. of rectified spirit, $\frac{1}{4}$ oz. cinnamon in powder, 1 oz. ginger in powder. The acid is gradually added to the spirit, and the mixture being placed in a closed vessel, is allowed to digest at a gentle heat for three days; the cinnamon and ginger are then added, and after being allowed to stand about six days, the whole is strained through cloth. The elixir of vitriol is useful for quenching thirst, sharpening the appetite, checking profuse perspiration, and often reducing the action of the pulse. The dose may range from 10 to 40 minims, and is administered in a wine-glassful of water, or some mild liquid, as infusion or conserve of roses.—**ELIXIR VITÆ OF MATHIOLUS** is composed of alcohol, and upwards of twenty aromatic and stimulating substances, and was at one time administered to patients suffering from epilepsy.

ELIZABETGRAD, a t. of South Russia, is situated in the midst of a delightful plain, on the banks of the Ingul and the Balta-Kremenchug railway, in lat. $48^{\circ} 27' N.$, long. $32^{\circ} 15' E.$, about 152 m. n. from Kherson. It consists of a town proper and four suburbs, is well built, its streets straight, wide, and adorned with avenues of trees. E. has a large arsenal within the walls. A considerable trade is carried on here in the produce of the surrounding districts and in leather goods. Manufactured goods are imported largely from Odessa. Great numbers of cavalry are always present in E., as it is the head-quarters of the military colonies e. of the river Bug. Pop. '92, 59,770.

ELIZABETH, a city and co. seat of Union co., N. J.; on Newark bay and Staten Island sound, 12 m. s.w. of New York, on slightly elevated ground on both sides of the Elizabeth river; reached by the New Jersey Central, the Pennsylvania, the Baltimore and Ohio, and the Philadelphia and Reading railroads. It was settled under the name of Elizabethtown in 1665, and was the capital of N. J. from 1755 to 1757. It is well laid out with broad and well-graded streets, and contains several small parks and many handsome residences. It is the home of a large number of men who do business in New York. The port is accessible for vessels of 300 tons, and receives large quantities of coal and iron brought by rail from the Pennsylvania mines for transshipment. A line

of steamboats plies daily between Elizabethport and New York; water is supplied from driven wells and the Elizabeth river; the streets are lighted with gas and electricity and paved. The property of the city was assessed in 1896 at over \$16,500,000. Among the public institutions are a general hospital, orphan asylum, home for aged women, Alexian Brothers hospital, public library, and several theatres. There are two collegiate schools for young women, a business college, several public and private schools, numerous churches, and daily and weekly newspapers. The principal manufactures are of sewing-machines, pottery, stoves and furnaces, engines, carpets, steam radiators, fertilizers, jewelry, chemicals, and ships. There are also several foundries, breweries, and tanneries. There are national and savings banks, several insurance companies and building loan associations and electric lights and street railroads. Among the points of special interest are the old tavern where Washington stopped when on his way to New York to be inaugurated president; Gen. Winfield Scott's house; the Boudinot house; and the old Livingston mansion. Pop. 1890, 37,764.

ELIZABETH, Queen of England, was the daughter of Henry VIII. and the unfortunate Anne Boleyn, and was b. 7th Sept., 1533. While she was yet in her third year, her mother was beheaded. After her mother's execution, she was sent to the country, where, in comparative poverty and seclusion, under the care of ladies who leaned to the "new learning," and sometimes, though seldom, with the companionship of her brother Edward, or her sister Mary, the greater part of her early youth was spent. When Catharine Parr became queen, E., who was a favorite with her, was more seen at court; but from some unknown cause, she incurred her father's displeasure, and was again sent to the country. Her father died when she was 13 years old. During the reign of her brother Edward, her life passed quietly and peacefully. She was then remarkable for a great demureness and sobriety of manner, discoursing with her elders with all the gravity of advanced years. Edward used to speak of her as his "sweet sister Temperance." During her sister's reign, this demureness was exaggerated into prudery, and the vanity which, in after years, with ampler means at its command, displayed itself in the utmost profusion of personal decoration, then sought for distinction by excess of plainness. Her Protestantism, and the way in which court was paid to her by the Protestant nobility, caused uneasiness to Mary and her council. On her sister's command, she conformed to papacy, but the insincerity of the conformity imposed upon no one. Upon the pretext of having been concerned in Wyatt's rebellion, she was sent in 1554 to the Tower. She entered it with all the gloomy forebodings which the fate of so many royal ladies who had been recently within its walls, could suggest. In daily fear for her life, many months passed. Indeed, the warrant for her execution was at one time prepared; and it is unquestionable that the stern bigotry of Mary and her counselors, Gardiner and Bonner, would have sacrificed E., but for the fear of popular commotion. The people, however, regarded E. with great favor, and many already looked forward to the time when the death of Mary should free the court from foreign influence, and give room for a milder government. Thus the life of E. was saved, but for some time longer she was kept a prisoner at Woodstock. During the remainder of Mary's reign, E., though occasionally at court, resided chiefly at her residence of Hatfield house, in Hertfordshire, where she occupied herself with feminine amusements, and the study of classical literature, under the learned Roger Ascham.

When Mary died (17th Nov., 1558), E. was 25 years of age. Her accession was welcomed alike by Catholic and Protestant. The former were, outwardly at least, the majority in Mary's reign; but among them were few who really cared for the peculiar doctrines of the Roman church, and there were many who were weary of priestly interference, foreign dictation, and cruel persecution. Like E. herself, there were many who had conformed merely to save themselves from trouble. They had obeyed the Six Articles in Henry's time; had agreed to the Protestant settlement of Edward; had turned with queen Mary, and were now ready to turn again with queen Elizabeth. The Protestants, of course, who had never believed the sincerity of E.'s conformity, welcomed her to the throne. E. then began, amidst dangers and difficulties, a reign which, contrary to the expectation of all, was of unexampled length and prosperity. It would be wrong not to attribute to her influence some effect in producing the great changes which, during the next 44 years, took place in England; but so far as these changes were not produced in the natural course of the development of the nation's powers, and so far as they bear the mark of an individual mind, they bear much more the impress of the bold yet cautious judgment and clear intellect of the great minister, Cecil, than of the sovereign's will. It is to the highest praise of E. that her first act on succeeding was to consult with such a man, and that to the very last she could bend her capricious temper to his control.

How the government influence was to be directed, was not long in being shown. Till parliament should meet, E. issued a proclamation that the English language should be used in the greater part of the church service, and that the host should not be elevated by the priest during mass. This sufficiently indicated into what hands power

had passed, and was enough to throw the mass of the indifferent to the side of the Protestants, and to cause a Protestant majority to be returned to E.'s first parliament. The acts of this parliament must be ever memorable in our history. It was then that England took its position as a Protestant power. The Book of Common Prayer, retaining, doubtless, some mixture of mediæval thought, but still vivid with new energy, was appointed to be used in all churches; the Thirty-nine Articles were settled as the national faith; the queen was declared to be head of the church. Thus all allegiance to Rome was thrown off. This revolution was soon accomplished and with little turmoil. The bishops, with one exception, refused to conform; but as a sign of the times, marking how thoroughly the priesthood must have become demoralized before their power was lost, it is noteworthy that of the 9,000 clergymen who held livings in England, there were fewer than 200 who resigned, rather than obey the new order of things.

The policy of E.'s ministers was one of peace and economy. They found the nation at war with France and Scotland, and one of their first acts was to secure peace upon favorable terms. Ever afterwards, they followed the same path. No war was undertaken in her reign for the sake of territorial conquest. To strengthen her own throne, E. secretly succored the Protestants in Scotland, in France, and in the Low Countries; but she had few open wars. To be at peace with a government, nay, apparently to be upon the most amicable terms with it (as E. was with the French court, while she sent assistance to the Huguenots at Rochelle), and at the same time to aid its rebellious subjects, was in those days thought only part of the politic dissimulation, without which, it was believed, no nation could be safely ruled. To maintain the security of her own throne, and to prevent foreign interference in English matters, was the mainspring of E.'s foreign policy; and she lost no opportunity of weakening and finding occupation abroad for any foreign power that unduly threatened her authority.

The one great blunder of England's policy was the treatment of Mary Queen of Scots. Had E. pursued a straightforward course, when her rival was thrown into her hands, much evil might have been spared. Some of the English ministers were prepared to take effectual measures to remove a life which might be turned into so dangerous a tool in the hands of Catholics. E. shrank from that course, but had not the courage and generosity to set queen Mary at liberty. Had this course been taken, Mary would have gone to France or Spain, would have made a foreign marriage, and as a foreigner would have lost the only sources of her real power—the sympathies of the Scotch and English Catholics. As it was, E. retained her a prisoner, and thus for years gave cause to conspiracy after conspiracy among the English Catholics. For a rebellion incited to set Mary free, the richest and most popular of the English nobility, Norfolk, was executed. The discovery of every new plot led to demands, on the part of parliament, for the execution of Mary. The plots then took a graver aspect. The assassination of E., and the placing of Mary on her throne, became the object. On the discovery of Babington's conspiracy for this purpose, the popular cry was irresistible, and was joined in by Cecil and Walsingham, and others of E.'s ministers, who had sinned too deeply against Mary to run the risk of her succession to the throne. With reluctance and hesitation, the sincerity of which need not be questioned, E. consented; and Mary, after long years of confinement, was condemned and executed.

This led to new evils. The participation of the Catholic party in the plots was retaliated by persecution. Many suffered under an act passed in 1585, making it treason for a Catholic priest to be in England, and felony to harbor one. These cruel measures were the ultimate means of bringing upon England the most menacing foreign attack which she had suffered. Philip of Spain had long meditated vengeance against England. The greatest state in Europe, enriched by splendid acquisitions in the new world, could ill brook that a power of the second rank should incite rebellion among her subjects in the Netherlands, should aid the Protestants in their desperate struggle against Alva, and allow its ships (little better than pirates, it must be confessed) to enter the Spanish harbors, and cut out the rich laden galleons. These were the real reasons: to restore the Catholic faith, and to revenge the death of a Catholic queen, furnished ostensible reasons. Years had been spent in preparation. In 1588, the "invincible armada" sailed from the Tagus, manned by 8,000 sailors, and carrying 20,000 soldiers. To aid these, a land-army of 100,000 men was to be transported from the Netherlands under the duke of Parma. The news roused all England, and every man who could carry arms—Protestant and Catholic from 18 years of age to 60—was enrolled in the forces. The old queen herself rode at Tilbury, energetically encouraging the army. A fleet of 200 vessels and 15,000 seamen gathered itself on the southern coasts, and waited the attack. Superior skill and courage gained the victory for the English; and what these had begun, the force of the elements completed. The splendid armada was broken and destroyed before it could join the land-army, not a soldier of which ever left foreign ground; while not a seaman of the fleet, save those whom shipwrecks sent, ever set foot on English ground.

E. died on 24th Mar., 1603, having lived nearly 70, and reigned nearly 45 years. If the life of her rival, Mary of Scotland, read somewhat like a tragedy, the private life of E. might afford abundant materials for comedy. Always parading her wish to live an unmarried life, E. coquetted with suitor after suitor till long after that period of life

when such proposals verge upon the ridiculous. Of her father's schemes to marry her to the Scotch earl of Arran or to Philip the son of Charles V.—afterwards husband of Mary—it is unnecessary to speak, for E. had personally little to say in regard to them. But she was scarcely more than a child when her flirtations with the handsome lord admiral Seymour—the brother of the protector Somerset—had passed the bounds of decorum. In Mary's reign, E. was flattered with the attentions of her kinsman, the earl of Courtenay, and she declined the hand of Philibert of Savoy, pressed on her by her sister's council. When queen, with some hesitation she refused the offer of Philip II., who was desirous of perpetuating his influence over England, and she began that connection with Leicester, which so seriously compromised her character. It is certain that she loaded him with honors as soon as she had them to bestow; allowed him to become a suitor for her hand within a few days after the sudden death of his wife, Amy Robsart, attributed by all England to his agency; and allowed him to remain a suitor long after his open profligacy had disgusted the nation, and had even opened her own eyes to his worthlessness. If we credit the scandal of the times, the intimacy was of the most discreditable kind. If we credit those sources of information, recently turned to more profit by Mr. Froude than by any of his predecessors, which are found in the dispatches of the bishop of Aquila, ambassador of Philip II. in London, preserved in the archives of Simancas, not only was the moral character of E. sullied with the darkest crimes, but even the quality for which she has ever been most honored, her English patriotism, was mere affectation. These dispatches represent her as accessory—at least, after the fact—to the murder of Amy Robsart, and as offering to Spain to become a Catholic, and to restore the Spanish ascendancy in England, if Philip would support her on the throne as the wife of Leicester; and they represent her as being restrained from giving way to the fatal consequences of her wild passion only by Cecil's control. That there is some basis of truth in this revelation, it is scarcely possible to deny; but the hatred with which Philip regarded E., after her refusal to marry him, has undoubtedly led the courtly bishop to gross exaggerations. It is undeniable, however, that had E. followed her own inclinations, she would have married Leicester. Her ministers, wisely for the nation, prevented this, but E. never seriously entertained another proposal. Cecil could prevent her marrying whom he would not, but he could not force her to marry whom he would. Among less distinguished suitors, the archduke Charles of Vienna, and prince Eric of Sweden, pressed their suit in vain. Petitions from parliament to the queen to marry, only excited her maidenly wrath, and produced dignified replies that she would attend to the matter when the time came. Years passed on, and she remained a spinster. Catharine of Medici, queen-mother of France, intrigued to marry her to one of her sons, Henry of Anjou (afterwards Henry III.), or the duke of Alençon, afterwards duke of Anjou. When the foreign envoys pressed the suit of the latter, E. was 38 years of age, and her suitor 19; but they ingeniously flattered her that she and he looked of the same age, for she, by her good preservation, looked nine years younger than she was; while the duke, by his wisdom, gravity, and mature intellect, looked nine years older. This flattery, with more plausible attractions, was without effect.

E.'s position gave too much scope for the development of the unamiable and ridiculous features of her character. The personal vanity displayed in her extravagant dress, her conversation, her "high and disposed" dancing, excites a smile, not lessened when we read of the irritable mistress boxing the ears of her councilors, cuffing her attendants, indulging in expressive masculine oaths, and amusing herself with rough masculine sports. The assertion that she was of a cruel disposition is false. That she could do cruel things when her vanity was concerned is sufficiently attested by her ordering the right hand of a barrister, named Stubbes, to be struck off for writing a remonstrance against her marriage with the duke of Alençon, which she thought unduly reflected on herself; but in her reign, the reckless waste of human life which marked the reigns of her predecessors was unknown. She was not, however, of fine feelings. Her brother could compliment her on the calm mind and elegant sentences with which she replied to the communication of the death of her father. On the news of her sister's death, she burst out with rhapsodical quotations from the Psalms; and when she heard of the execution of her lover Seymour, she turned away the subject with something like a jest. By her attendants, she was more feared than loved. The one quality which never failed her, was personal courage; and when she chose, her demeanor was stately and royal. Religion was with her, as with a great proportion of the nation at that time, a matter more of policy and convenience than of feeling or principle. She preferred Protestantism, from early associations, because it gave her the headship of the church, freed her from foreign interference, and was more acceptable to her ministers and to the nation. But she had conformed in Mary's time to Catholicism with little difficulty; and, had there been necessity for it, she would rather have reigned a Catholic than not have reigned at all. To the last, she retained in her private chapel much of the ritualism of the Roman church; and while refusing her Catholic subjects the exercise of their religion, she entertained the addresses of Catholic suitors. How thoroughly incapable she was of appreciating a matter of religious principle may be gathered from the fact, that she looked upon the great Puritan movement, destined soon afterwards to play so impor-

tant a part in the nation's development, as some frivolous controversy about the shape of clerical vestments. Of toleration, then well enough understood by Bacon and the more advanced spirits of the age, she had no conception.

What makes the name of E. so famous, was the splendor of her times. In her long reign, the true greatness of England began. Freed from the possession of those French provinces which rather harassed than enriched—with little domestic commotion—with no great foreign wars—with an almost complete immunity from religious persecution, the nation turned to the arts of peace. An unequaled literature arose. The age that produced Spenser, Shakespeare, and Bacon could not be other than famous. Under Frobisher and Drake, maritime adventure began, and the foundations of our naval force were laid. Commerce, from being a small matter in the hands of a few foreign merchants, developed itself largely. The exchange of London was opened in E.'s time; and in the charter which she granted to that company of merchant adventurers, which afterwards took the name of the East India company, may be seen one of the small beginnings of our vast colonial empire. The social condition of the people also greatly improved in her reign. The crowds of vagabonds which the monastic institutions had fostered, and who had pillaged the country in all ways on the secularization of the monastic property, died out, or were absorbed in industrious employments. The last traces of bondage disappeared. Simultaneously with the growth of greater comfort and intelligence in the people, parliament began to assert, with greater vigor, its constitutional rights. The right of the commons to free speech, and to initiate all money-bills, was steadily asserted, and the right of the crown to grant monopolies, or to issue proclamations having the force of law, vigorously assailed. In the later years of her reign, the attempts of E. to gain arbitrary power, and her caprices, had forfeited the popularity which she so anxiously cultivated. But after her death, her fame revived; and during the time of the Stuarts, amid the jealousy of the Scotch, the troubles of the civil wars, and the hatred of a Catholic sovereign, the nation looked back with fond regard to the long reign of the "Good Queen Bess," when peace had prevailed, and the government had been thoroughly English. See Church, *Elizabeth* (1889).

ELIZABETH, QUEEN OF ROUMANIA; b. 1843, a princess of Wied Neuwied, and married to King (then Prince) Charles of Roumania in 1869. Under the name of *CARMEN SYLVA*, she has written a number of books in verse and prose, among them *Stürme Leiden's Erdgang*, tr. into English by Helen Zimmern as *Pilgrim Sorrow*; *Jehovah*; *Pensées d'une Reine*, etc. In 1890 she visited England and Wales.

ELIZABETH, SAINT, daughter of Andreas II., king of Hungary, was b. at Presburg in 1207. At the age of four, she was affianced to the landgraf of Thuringia, Louis IV., called the pious, and brought to his court to be educated under the eyes of the parents of her future husband. She early displayed what may be called a passion for the severities of the Christian life, as it was conceived in those days. She despised pomp, avarice, ambition; cultivated humility, and exhibited the most self-denying benevolence. Her conduct, even as a girl, astonished the Thuringian court; but such was the grace and sweetness of her disposition, and the excellence of her beauty, that Louis—though her affections seemed to be given wholly to God—still wished to marry her. They were united when E. was only 14. Louis himself, far from blaming the devout girl whom he had made his wife for her long prayers and ceaseless almsgiving, was himself partially attracted to a similar mode of life. A boy and two girls were the fruit of their union; but the happiness of E., in so far as it depended on anything earthly, was shattered by the death of her husband in 1227, when absent on the crusade headed by Barbarossa. Her confessor, Conrad of Marburg, a narrow fanatical monk (to whose miserable teaching E. mainly owed her perverted idea of life and duty), had trained her to stifle the emotions of her nature as sinful, and the poor widow hardly dared to bewail her loss. Great misfortunes soon befell her. She was deprived of her regency by the brother of her deceased husband, and driven out of her dominions on the plea that she wasted the treasures of the state by her charities. The inhabitants of Marburg, whose miseries she had frequently relieved, refused her an asylum, for fear of the new regent. At last she found refuge in a church, where her first duty was to thank God that he had judged her worthy to suffer. Subsequently, after other severe privations, such as being forced to take up her abode in the stable of a hostelry, she was received into the monastery of Kitzingen by the abbess, who was her aunt. When the warriors who had attended her husband in the crusade returned from the east, she gathered them round her, and recounted her sufferings. Steps were taken to restore to the unfortunate princess her sovereign rights. She declined the regency, however, and would only accept the revenues which accrued to her as landgravine. The remainder of her days were devoted to incessant devotions, almsgivings, mortifications, etc. There is something mournfully sublime in her unnatural self-sacrifice. We shudder even in our sympathy when we read of this beautiful tender-hearted creature washing the head and the feet of the scrofulous and the leprous. Murillo has a painting (now in the museum at Madrid) of this act of evangelical devotion. The solemn tragedy of her brief life assumed towards its close a ghastly intensity through the conduct of her confessor, Conrad, who, under pretense of spiritual chastisement, used to strike and maltreat her with brutal severity. The alleged cause of this was Conrad's aversion to her "squandering" her money among the poor. Perhaps he thought it should have gone

to him. At last her health gave way; and on the 19th Nov., 1231, at the age of 24, E. died, the victim partly of ill-usage and partly of a mistaken theory of religious life, but as gentle and saintly a soul as figures in the history of the middle ages. She was canonized four years after her death. See Montalembert's *Histoire de Sainte Elisabeth de Hongrie* (Paris, 1836). The Rev. Charles Kingsley's dramatic poem, entitled *The Saint's Tragedy* (London, 1848), is founded on the story of E.'s life.

ELIZABETHAN ARCHITECTURE, a term applied to the mixed style which sprang up on the decline of Gothic architecture. By some it is called the Tudor style, but that name belongs more correctly to the perpendicular, or latest kind of Gothic. The Elizabethan is chiefly exemplified by mansions erected for the nobility in the reigns of Elizabeth and James I., and originated in the first attempt to revive classic architecture, influenced, no doubt, by Holbein, who was patronized by Henry VIII., and furnished several designs in this manner. John of Padua succeeded him, and built in the mixed style a palace for the protector Somerset (for which purpose the cloisters of St. Paul's were taken down), and the mansion of Longleat for his secretary, sir John Thynne. The vast dimensions of the apartments, the extreme length of the galleries, and enormous square windows, are the leading characteristics of this manner of building. The ornaments both within and without were cumbersome; nothing could exceed the heaviness of the cornices and ceilings wrought into compartments; in short, the architecture was just in keeping with the dress of the period, rich and gorgeous, rather than elegant, graceful, and comfortable. The following examples of mansions of the 17th c. may be still seen near London: Holland house, Campden house; and the following in Kent: Sir T. Willow's at Charlton, the marquis of Salisbury's at Hatfield, and Knowle, the property of the duke of Dorset. The most eminent architects of those times were John Thorpe, Gerard Christmas, Rodolph Symonds, and Thomas Holt.

ELIZABETH CITY, a co. in s.e. Virginia, on James river and Chesapeake bay; 50 sq.m.; pop. '90, 16,168, incl. colored. Corn and wheat are the staple products. Co. seat, Hampton.

ELIZABETH ISLANDS, a group s.w. of cape Cod, between Buzzard's bay and Vineyard sound, forming the town of Gosnold, Dukes co., Mass. There are 16 islands, the most important of which are Naushon, Cuttyhunk, Pasque, and Nashawena; pop. of the whole group (permanent residents) about 100. The islands have a fine climate, and afford excellent fishing. On Cuttyhunk island the foundations of the first English colony of New England were laid, in 1602, by Bartholomew Gosnold, but the place was abandoned a few weeks later. On another island, Penikese (area 100 acres), a school of natural history, connected with Harvard college, was established 1873, but discontinued in a few years.

ELIZABETH PETROVNA, empress of Russia, daughter of Peter the Great and Catherine I., was b. in the year 1709. On the death of Peter II., in 1730, she allowed Anna, duchess of Courland, to ascend the throne, she herself being apparently indifferent to anything but the indulgence of her passions. Anna died in 1740, and Ivan, the son of her niece (also called Anna), an infant of two months, was declared emperor, and his mother regent during his minority. Shortly after this, a plot was formed to place E. upon the throne; the two principal agents in it were Lestocq, a surgeon, and the marquis de la Chetardie, the French ambassador. The officers of the army were soon won over; and on the night of the 5th Dec., 1741, the regent and her husband were taken into custody, and the child Ivan conveyed to Schlüsselburg. The leading adherents of Anna were condemned to death, but pardoned on the scaffold, and exiled to Siberia. By eight o'clock in the morning, the revolution was completed, and in the afternoon all the troops did homage to the new empress. La Chetardie was handsomely rewarded; and Lestocq was created first physician to the empress, president of the college of medicine, and privy counselor. E., however, did not possess the qualities requisite in a ruler. She wanted energy, knowledge, and love of business, and allowed herself to be guided by favorites. In order to strengthen her position, E. took pains to win over her nephew, the young prince Peter, the son of her sister, the duchess of Holstein-Gottorp. She summoned him to Petersburg in the year 1742, and proclaimed him her successor. E. took part in the Austrian war of succession, and in spite of the opposition of France, dispatched an army of 37,000 men to the assistance of Maria Theresa, and thereby hastened the conclusion of the peace of Aix-la-Chapelle in 1748. E. showed herself less placable towards Frederick II., against whom she cherished a personal enmity, excited by some severe expressions he had employed respecting her. At the commencement of the seven years' war, she allied herself with Austria and France, and marched her troops into the Prussian states. Her troops gained the victory in the battles of Grossjägerndorf and Kunersdorf, and took possession of Berlin, but without any decisive result. E. died before the expiration of the war, 5th Jan., 1762. She founded the university of Moscow and the academy of art at St. Petersburg. Though no person was put to death during her reign, the most shocking punishments were inflicted, and thousands were exiled to Siberia and Kamtchatka. E. had several illegitimate children. Profligacy, espionage, and persecution reigned in her court, the administration of justice was restrained, and the finances neglected; but E. was nevertheless extremely strict in the observance of the public ordinances of religion.

ELIZABETH STUART, queen of Bohemia, remarkable not only as a heroine, but as forming the connecting link between the ancient royal families of England and Scotland and the present reigning dynasty, was b. in the palace of Falkland (q.v.) on the 19th of Aug., 1596. On the accession of her father, James VI. of Scotland, to the crown which fell to him by the demise of queen Elizabeth, in 1603, she accompanied the family to England, where she was educated. On the 14th of Feb., 1613, E. was married to Frederick, elector-palatine, whom she soon after accompanied to his residence, the castle of Heidelberg (q.v.); see also **PALATINATE**. When the Protestant princes of Germany sought for a fitting person to fill the throne of Bohemia, they made choice of Frederick, who accepted the perilous honor, partly, perhaps, from the ambition of his wife, who is alleged to have longed for the title of queen. The palatine removed with E. and three children to Prague, which they entered Oct. 21, 1619. Frederick and E. occupied the throne of Bohemia only about a year. By the forces of the Catholic league, the army of Frederick was routed at the battle of Prague, Nov. 8, 1620, and the royal family fled into exile, for already the palatinate was laid waste. With her husband and children, and a few faithful attendants, E. took up her residence at the Hague, and ever afterwards the family lived in a state of dependence. E. was the mother of 13 children, the eldest of whom was accidentally drowned in Holland, and 3 others died young. The next were Charles-Louis and Rupert, and, following in order, were Elizabeth, Maurice, Edward, Philip, Louisa, Henrietta-Maria, and Sophia. From this numerous offspring, E. derived little comfort in her misfortunes. Charles-Louis was a selfish, calculating person, with low, disreputable habits. Rupert (q.v.) the "mad cavalier," and his brother, Maurice, fought in England during the civil war, and, after the loss of the royalist cause at the battle of Naseby, they betook themselves to the sea, and for some time were little better than pirates. Edward, in 1645, abjured Protestantism, and was admitted into the Roman Catholic church. Philip committed an assassination at the Hague, fled from justice, became a soldier of fortune in France, and was slain in the civil wars. Elizabeth accepted the office of superior of the Lutheran abbey of Hervorden, Henrietta-Maria was espoused by Ragotzi, prince of Transylvania, but died shortly after her marriage. Louisa fled to France, and died as abbess of Maubisson. Previous to these events, E. became a widow by the death of Frederick, Feb. 17, 1629, when his right to the palatinate devolved on Charles-Louis, who, by the treaty of Westphalia, was restored to the family inheritance, Oct. 24, 1648. This favorable turn of affairs did not mend the fortunes of E., who was scandalously neglected by her son, the young elector-palatine; and all he would do for the family was to give a shelter to his youngest sister Sophia, until she was married to Ernest-Augustus, a scion of the house of Brunswick, who ultimately succeeded to the electorate of Hanover.

Deprived, in one way or other, of all her children, the queen of Bohemia—by which title she continued to be known—resolved to quit Holland. Relieved of her debts by the sale of jewels, and by aid of a pecuniary subsidy from the British parliament, she embraced an invitation from her nephew, Charles II., to come to England. She arrived May 17, 1661. From this time she was in a great measure indebted to the hospitality of lord Craven, in a mansion which he had purchased from sir Robert Drury, in Drury lane, London. Charles II. paid her little attention; but at her death, which occurred Feb. 13, 1662, he caused her remains to be interred in Westminster abbey. Charles-Louis, her son, died in 1680, leaving a son, who died without issue, and the palatinate then went to a distant branch of the family; he left also a daughter, Charlotte-Elizabeth, who, in 1671, had married Philip, duke of Orleans, only brother of Louis XIV. In 1674, she gave birth to a prince, who became the noted regent of France during the minority of Louis XV. She died at St. Cloud in 1722. The late Louis-Philippe, king of the French, was her lineal descendant. When, in 1708, the question of succession to the crown of Great Britain was debated, it was found that all the descendants of James I. were either dead or were Roman Catholics, except Sophia, electress of Hanover, and her family. By act of parliament, that year, the crown was accordingly secured to her and her descendants, "being Protestants;" and in virtue of this act of settlement, on the death of queen Anne, Sophia would have ascended the throne, but she predeceased the queen three months, and her son became sovereign of the realm as George I., Aug. 12, 1714. In this extraordinary and unforeseen manner did a grandson of the unfortunate queen of Bohemia become king of England, and originate the dynasty of the reigning monarch. The *Memoirs of Elizabeth Stuart, Queen of Bohemia*, by Miss Bengier, 2 vols., may be perused as an accurate and pleasing piece of biography.

ELIZABETO'POL, a government in Asiatic Russia bordering on Persia; 16,721 sq. m.; pop. 793,969. The principal city bears the same name.

ELIZABETO'POL, a t. of Russian Transcaucasia, is situated in lat. 40° 42' n., long. 46° 20' east. It was formerly an Armenian town, afterwards a Turkish fortress and in 1813 was annexed to Russia. Its principal buildings are its churches and mosques, of which there are many. The town is remarkable for its numerous fruit-gardens and vineyards. Pop. about 21,000.

ELK, a co. in s.e. Kansas; formed and organized, 1875; crossed by Elk river; surface nearly flat, soil fertile; 651 sq. m. Pop. '90, 12,216. Co. seat, Howard.

ELK, a co. in central n.w. Pennsylvania, on the head waters of Clarion river, intersected by the Buffalo, Rochester, and Pittsburg and the Pennsylvania railroads; 760 sq. m.; pop. '90, 22,239. The surface is rough; coal-mining and lumbering are the leading occupations. Co. seat, Ridgway.

ELK, IRISH, *Megaceros Hibernicus*, a large deer found in the pleistocene strata. There is a double error in its popular name, for it is a true deer, between the fallow and reindeer, and though abundant in Ireland, it is not peculiar to that country, being found also in England, Scotland, and on the continent of Europe. In Ireland, it occurs in the shell marl underlying the extensive turbaries. In England, lacustrine deposits and brick-clay contain its remains, and, associated with the mammoth and rhinoceros, they are found also in ossiferous caves. The most striking feature in this animal was its enormous antlers. A straight line drawn between their extreme tips in one specimen measured 10 ft. 10 inches. The form of the antler differs from that of any living species of deer. The beam enlarges and flattens into a palm; a brow snag exists as in the fallow-deer, but in adult specimens, this bifurcates and expands somewhat as in the reindeer—a peculiarity never observed in the fallow-deer group. The antler is also furnished with a back snag. Some idea of the enormous size and weight of the antlers may be formed from the fact that, in a specimen where the head weighed 5½ lbs., their weight was 81 lbs. To sustain this, the vertebræ of the neck and the limbs are very much larger and stronger than in any other deer. A fine and almost perfect specimen of this animal, from the Isle of Man, exists in the Edinburgh museum.

ELK, MOOSE, or MOOSE DEER, *Alces malchis*, or *cervus alces*, the largest existing species of the *cervidae*, or deer family, is a native of the northern parts of Europe, Asia, and America. When full grown, it is about 6 ft. in height at the shoulders, and sometimes weighs 1200 lbs. The body is round, compact, and short; the neck is short and thick, unlike that of deer in general, but thus adapted for sustaining the great weight of the head and horns. The head is very large, narrow, about 2 ft. long. The horns in males of the second year are unbranched, not flattened and about 1 foot long; as the animal becomes older, they begin to display a blade, with more numerous snags, and in mature elks the blade becomes very broad, the snags sometimes 14 on each horn; a single antler has been known to weigh about 60 lbs. The horns have no basal snag projecting forwards. The ears are long, and have been compared to those of the ass. The eyes are small. The limbs are long, and very graceful. The tail is only about 4 in. long. The body is covered with coarse angular hair, which breaks when it is bent. On the neck and withers there is a heavy mane, and the throat is covered with long hair. A large goitre-like swelling under the throat of the younger elks has a very curious appearance. The hoofs of the E., like those of the reindeer and of the buffalo, are so constructed as to part widely, and to afford a better footing on soft marshy ground or on snow; they make a clattering when it runs. In running, it carries its muzzle forward, with the horns thrown back upon the neck, so that they may not be caught by branches. Its shoulders being higher than the croup, its common gait is a shambling trot; but it can also gallop with great rapidity. The color of the elk is brownish black, darker in winter than in summer; the limbs, the sides of the head, and the mane are of a lighter color than the body. Elks are sometimes seen in small herds, but often singly; they are now very rare in Europe, and are no longer found in parts of North America in which they were once common. They formerly extended as far s. as the Ohio. They are sometimes seen even on the shores of the Arctic ocean. They delight in marshy districts and in forests. When compelled to eat grass, they must get down on their knees to reach it; their proper food consists of the branches and foliage of shrubs and trees. They are very timid and inoffensive, except during the rutting season. A single stroke of an elk's fore-foot is sufficient to kill the strongest dog. It is also an extremely wary animal, and is with the greatest difficulty approached by the hunter. Its sense of smell is very acute, and the slightest sound excites its alarm. It is, however, much sought after in North America. In Sweden, its destruction is prohibited; and in Norway is placed under legal restrictions. The flesh of the elk is esteemed a good kind of venison; the fat is remarkably soft; the nose and the tongue are reckoned delicacies. The skin is used for a variety of purposes.

The elk is easily domesticated, and was at one time employed in Sweden for conveying couriers, being capable of traveling more than 200 m. in a day when attached to a sledge. See illus., DEER, ETC., vol. IV.

ELK CREEK, a magisterial dist., Grayson co., Va.; containing the town of Independence. Pop. '90, 5486.

ELKESAITES, or **ELCESAITES**, Jewish Christians of the 2d c., who held as the highest authority a work known as the *Book of Elcai*. This book was known to Origen, who reports that it was believed to have fallen from heaven, and was revealed by an angel who was the son of God. Its contents were made known only upon a pledge to keep them secret. Apparently the object of the sect was to mingle Judaism and Christianity, so that the Hebrews of that day could embrace the new doctrines without entire repudiation of their old belief. The fullest account of the *Book of Elcai* is found in the *Philosophoumena* of Hippolytus.

EL-KHAR GEH, capital of the Great Oasis, Upper Egypt, is situated in lat. 25° 28' n., long. 30° 40' east. In the vicinity of the town are numerous ruins, among which are those of a temple; there is also a remarkable necropolis.

ELKHART, a co. in n. Indiana, on the Michigan border, intersected by the St. Joseph's river and the Lake Shore and Michigan Southern railroad; 470 sq. m.; pop. '90, 39,201. The surface is generally level, with extensive oak and maple forests. The soil is fertile, producing wheat, corn, etc. Co. seat, Goshen.

ELKHART, a city in Elkhart co., Ind., on St. Joseph's river, and Lake Shore and Michigan Southern and other railroads, 101 m. e. of Chicago. It has fine churches and schools, and abundant water-power, supplying a rolling-mill, railroad shops, carriage, paper, starch, chewing-gum, bicycle, printing press, and musical instrument factories; electric light and water-works, several banks, electric street railroads, business colleges, and daily, weekly, and monthly periodicals. Pop. '90, 11,360.

ELKINS, STEPHEN BENTON, b. O., 1841, graduated from the Mo. univ., 1860; was a member of the territorial legislative assembly of N. Mex.; and was atty.-gen. and U. S. dist. atty. in that territory. He was elected as a republican from N. Mex. to the XLIII and XLIV congresses. E. was one of the defendants in the "Star Route" trials, and was acquitted, 1882. He became secretary of war in 1891, and U. S. senator from West Virginia in 1894.

ELKO, a co. in n.e. Nevada, drained by the sources of the Humboldt and Owyhee rivers, and crossed by the Southern Pacific railroad; 17,652 sq. m.; pop. '90, 4794. The surface is rough, five or six mountain ranges running n. and s. There are valuable mines, especially of silver. Co. seat, Elko.

ELL (allied to elbow, Ger. *ellenbogen*, Lat. *ulna*, the fore-arm or arm in general) is a measure of length now little used. It was originally taken in some vague way from the arm, and hence has been used to denote very different lengths. The Latin *ulna* appears to have denoted sometimes the measure from the elbow to the tips of the fingers, sometimes that between the outstretched hands. The English ell, as a measure of cloth, is equal to five quarters of a yard (q.v.).

ELLAG'GIC ACID, a constituent of animal secretions such as the bezoar stones found in the antelope. It may be produced by the decomposition of gallic acid.

ELLENBOROUGH, EARL OF. Edward Law, first earl of E., son of the first baron (many years chief-justice of the king's bench), was b. 1790; educated at Eton and at St. John's college, Cambridge, where he graduated M.A., 1809; succeeded his father in the barony in 1818; was lord privy seal in the duke of Wellington's administration, 1828-29; president of the board of control during the short-lived Peel administration of 1834-35; and appointed, on the return of sir Robert Peel in Sept., 1841, to the same office, which he relinquished a month afterwards for the post of governor-general of India. He received the thanks of parliament in 1843 for his "ability and judgment" in supporting the military operations in Afghanistan. In many other respects, his Indian administration was open to censure. He was charged with reserving his favor for the military, and inflicting undeserved slights upon the civil servants of the company. He made showy progresses; addressed proclamations to the rulers and natives of India which appeared to sanction idolatry; and, finally, in his proclamation concerning the sandal-wood gates of the temple of Juggernaut, when brought back from Ghuznee, he reached the climax of a series of extravagances, which induced the directors of the East India company to exercise a power only used in extreme cases, and to recall him. The ministry, however, stood by him, and he was created by the crown an earl and a viscount; he also received the distinction of G.C.B. In 1846, sir R. Peel made him first lord of the admiralty, an office which he resigned in July of the same year, when the disruption of the Peel administration took place. In the Derby administration of 1858, he was again minister for India, and the author of an India bill, which failed to obtain the sanction of parliament. Having permitted a dispatch to see the light, in which he had administered a severe and caustic rebuke to viscount Canning, governor-general of India, an outcry was raised against him, which threatened the existence of the Derby government. To avert this result, lord E. resigned. He afterwards took a frequent and influential part in the debates of the upper house. He was styled, by no less a judge than M. Guizot, "the most brilliant of the tory orators." He was twice married—first to a daughter of the marquis of Londonderry, and second to the daughter of Admiral Digby. His divorce from the latter made some noise at the time. E. died without issue, Dec. 22, 1871, when the earldom and viscounty became extinct.

ELLENBOROUGH, EDWARD LAW, Lord, 1750-1818; chief-justice of the court of king's bench; educated at Cambridge, and a fellow of Trinity college; studied law, and was called to the bar in 1780, speedily gaining a large practice and a high reputation. He was principal counsel for Warren Hastings in the famous impeachment trial. He began political life as a whig, but the French revolution made him a supporter of Pitt. In 1801, he was appointed attorney-general; the next year he succeeded to the king's bench as chief-justice, and at the same time was made a peer. He was also a member of the Grenville cabinet. As a judge he showed profound legal knowledge, and was especially an authority on mercantile law; but he was harsh and overbearing to counsel, and generally against any prisoner tried for a political offense. In the trial of Hone for blasphemy he directed the jury to return a verdict of guilty, but they brought in one for acquittal—an event which is thought to have hastened the judge's death.

ELLENRIEDER, MARIE, a female painter of very high excellence, was b. at Constance in 1791, studied in Munich, and in 1820 went to Rome, to perfect her knowledge

of art. Her admiration of the old German masters gave a religious bent to her genius. On her return to Germany, she resided for some time at Carlsruhe, where she painted a "Martyrdom of St. Stephen" as an altar-piece for the Roman Catholic church. She was afterwards appointed court-painter at Munich, but she chose to fix her residence at Constance, and devoted herself exclusively to her profession. Among her principal pieces are the "Transfiguration of St. Barthelemy;" "Christ Blessing Little Children;" "Mary and the Infant Jesus;" "Joseph and the Infant Jesus;" "St. Cecilia;" "Faith, Hope and Charity;" and a Madonna. Marie E. is reckoned in Germany the greatest female artist of the present age. So full of ideal grace and beauty are the heads of her women and children, in particular, that it has been said that "she seems to paint in the presence of angels;" her coloring, however, is gray, dull, and somber, like that which prevails among the old masters of the German school. She died in June, 1863.

ELLERY, WILLIAM, 1727-1820; b. R. I.; graduated at Harvard, and went into trade in Newport; afterwards began the practice of law, and in 1776 was elected to the continental congress, where, with his fellow member from Rhode Island, Stephen Hopkins, he signed the declaration of independence. With the exception of the two years 1780 and 1782 he was in congress until 1786, and was one of the most influential members. In 1790, he was appointed collector of customs at Newport, and held the office during life.

ELLESMERE, a t. in the n.w. of Shropshire, near a beautiful lake or mere, 19 m. n.n.w. of Shrewsbury. The Ellesmere canal opens navigation between Chester and Ellesmere Port. On the present site of a bowling-green once stood an ancient castle, alternately held by the English and Welsh.

ELLESMERE, first EARL OF, politician, patron of the arts, and author. Francis Egerton, second son of the first duke of Sutherland, was b. 1800; graduated at Christ Church, Oxford, where he was second-class in classics, 1820; entered the house of commons, 1820, and represented successively Bletchingly, Sutherland co., and South Lancashire; filled the office of chief-secretary for Ireland from Jan., 1828, to July, 1830, and secretary at war from July to Nov., 1830; in 1833, assumed the name of lord Francis Egerton, in lieu of his patronymic Leveson-Gower. He achieved considerable literary distinction as a writer of graceful poems, translations from the German, etc. He also published a pamphlet on the defenseless state of the coasts and of the metropolis, which called forth some adverse criticism. He was a munificent patron of the arts, and made many valuable additions to the collection of pictures which he inherited with the large estates of the last duke of Bridgewater. He also built a noble gallery for their reception, which he liberally threw open to the public. After faithfully voting with the conservative party in parliament for a quarter of a century, he, on the retirement of the Peel administration in 1846, obtained a revival in his favor of the peerages of Ellesmere and Brackley. His last public appearance was in May, 1856, when he moved, in the house of lords, an address to the crown, approving of the treaty of peace after the war with Russia. He died in 1857 at his new mansion, Bridgewater house, London, and was succeeded in the earldom by his eldest son, viscount Brackley.

ELLET, CHARLES, JR., 1810-62; b. Penn.; an engineer, builder of the first wire suspension bridge in the United States (over the Schuylkill, at Fairmount, near Philadelphia); architect of the first suspension bridge over the Niagara river below the falls, and of the first one at Wheeling. During the war of the secession he built a number of steam rams for the western rivers, with which he took part in the battle in the Mississippi at Memphis, June 4, 1862, sinking or disabling a number of confederate vessels. He received a wound on that occasion, from the effects of which he died.

ELLET, ELIZABETH FRIES, 1818-77; b. N. Y.; wife of William H., and author of sketches, poems, etc. At 17 years of age she published a volume of poems, and about the same time wrote *Teresa Contarini*, a tragedy based on Venetian history. In 1841, she published *The Characters of Schiller*, following with *Women of the American Revolution*; *Evenings at Woodlawn*; *Family Pictures from the Bible*; *Domestic History of the American Revolution*; *Watching Spirits*; *Pioneer Women of the West*; *Novelettes of the Musicians*; *Summer Rambles in the West*; *Women Artists in All Ages and Countries*; *Queens of American Society*; and *Court Circles of the Republic*. She was also a frequent contributor to periodicals.

ELLET, WILLIAM HENRY, 1806-59; b. N. Y.; graduated from Columbia college, where he was professor of chemistry in 1832; in 1835, professor of chemistry, mineralogy, and geology in South Carolina college. The South Carolina legislature presented him with a testimonial for the discovery of a cheap method of manufacturing gun-cotton. His latest work was that of consulting chemist to one of the great gas manufacturing companies of New York.

ELLEZELLES, a large village of Belgium, in the province of Hainault. Linen-weaving is extensively carried on. There are several flour-mills, breweries, and a salt-refinery. Pop. about 5300.

ELLICOTT, ANDREW, 1754-1820; b. Penn. His scientific attainments caused his employment at various times for marking the boundaries of Virginia, New York, and Pennsylvania; and in 1789 he surveyed the country between Pennsylvania and

lake Erie, making the first accurate measurement of Niagara river. In 1790, he laid out the proposed city of Washington, now the federal capital, and in 1796 he was one of the commissioners to settle the southern boundary between the United States and Spanish territory. Later in life he was professor of mathematics at West Point. He was an active member of the American philosophical society, and a frequent contributor to the *Transactions* of that body.

ELLICOTT, CHARLES JOHN, D.D., b. 1819; bishop of Gloucester and Bristol. He graduated at Cambridge in 1841, and was ten years rector of Pilton, Rutlandshire, but in 1858 became professor of divinity in King's college, London, and in 1860, Hulsean professor of divinity at Cambridge. In 1861, he was made dean of Exeter, and in 1863 bishop. He is the author of a *Treatise on Analytical Statics*; *The History and Obligation of the Sabbath*; *Lectures on the Life of our Lord Jesus Christ*; and *Considerations on the Revision of the English Version of the New Testament*; but his most important works are *Commentaries* on a number of the New Testament Epistles, eminent for thoroughness of grammatical criticism. He was a member of the New Testament Revision Committee.

ELLICOTT CITY, city and co. seat of Howard co., Md., on the Patapsco River and the Baltimore and Ohio railroad, 10 m. w. of Baltimore. The water-power is abundant, and there are granite quarries, cooper shops, flour mills, Rock Hill and St. Charles's colleges, electric lights, national bank and weekly newspapers. Pop. '90, 1488.

ELLIOTT, a co. in n.e. Kentucky, drained by the head-waters of the Little Sandy river; area, 270 sq.m.; pop. '90, 9214, incl. colored. It is hilly, with much forest land. Productions, wheat, corn, etc. Iron ore and coal are found. Co. seat, Sandy Hook.

ELLIOTT, CHARLES, D.D., LL.D.; 1792-1869; b. Ireland, where he joined the Wesleyan Methodists, and prepared for the ministry. At the age of 23, he came to America, and in 1818 joined the Ohio conference; in 1822, he was superintendent of missions among the Wyandot Indians; afterwards for five years presiding elder of the Ohio district; then for four years professor of languages in Madison college (Uniontown, Penn.). He was a few years later presiding elder of the Pittsburg district, editor of the *Pittsburg Conference Journal*, and subsequently of the *Western Christian Advocate* (Cincinnati). In 1857, he became professor of Biblical literature and president of the Iowa Wesleyan university. About 1860, he became editor of the *Central Christian Advocate* at St. Louis. Among his works are *Treatise on Baptism*; *Delineation of Roman Catholicism*; *History of the Great Secession from the Methodist Episcopal Church*; *Political Romanism*; *Reminiscences of the Wyandot Mission*; *South-western Methodism*; works against slavery, biographies, etc.

ELLIOTT, CHARLES LORING, 1812-68; b. New York, the son of an architect. Having an inclination for painting, he became a pupil of Trumbull, and afterwards of Quidor. He was for some time in New York city, where his efforts began to attract attention. After working chiefly on portraits for several years in the w. part of the state, he returned to the city, where he soon became the chief of portrait painters, having at his easel many hundreds of the most eminent citizens.

ELLIOTT, CHARLES WYLLYS, b. Conn., 1817; a descendant of the "apostle to the Indians." He began business as a merchant in New York, took up the study of horticulture and landscape gardening with A. J. Downing, and practiced the business in Cincinnati. Returning to New York, he became one of the founders of the "Children's Aid Society," and was chosen a commissioner to lay out the Central Park. He d. 1883.

ELLIOTT, EBENEZER, the CORN-LAW RHYMER, was b. at Masborough, in Yorkshire, Mar. 7, 1781. His father was a man of strong character and narrow opinions, and as appears from Ebenezer's autobiography (published in the *Athenæum* in 1850), exercised no little influence on his son's modes of thinking and sympathies. When a boy at school, E. was not a quick pupil; and even after his father had sent him to work in the iron-foundry, where he himself held the situation of a clerk, the youth exhibited no fondness for reading. Before long, however, he entirely changed, and commenced to study Milton, Shakespeare, Ossian, Junius, and other authors. His first published poem was composed in his 17th year; it is entitled *The Vernal Walk*. This was succeeded by *Night*; *Wharnccliffe*; etc. In 1821, E. began business as an iron-founder on his own account at Sheffield. He was very successful; and in 1841 retired to an estate which he had purchased at Great Houghton, near Barnesley, where he died 1st Dec., 1849. E.'s principal productions are *Love*, accompanied with a letter to lord Byron; his famous *Corn-law Rhymes*; *The Ranter*; and *The Village Patriarch*, a work full of noble and earnest poetry, all of which appeared between 1823-31. In 1834, he issued a collected edition of his works, in 3 vols.; and in 1840, an edition in one volume. E. followed Crabbe, but with more depth and fire of feeling, in depicting the condition of the poor as miserable and oppressed, tracing most of the evils he deplores to the social and political institutions of the country. The laws relating to the importation of corn were denounced by E. as specially oppressive, and he inveighed against them with a fervor of manner and a harshness of phraseology which ordinary minds feel as repulsive, even while acknowledged as flowing from the offended benevolence of the poet. But the glow of earnestness kindles his verse, and hides a multitude of faults. More enduring, however, than his rhyming philippics, are his descriptions of English, and especially of Yorkshire scenery, and his delineations of humble virtue and affection. These are instinct with the purest spirit of poetry.

ELLIOTT, JESSE DUNCAN, 1782-1845; b. Philadelphia; midshipman in the U. S. navy in 1804, rising to capt. in 1818. He was in the *Essex* in the war with Tripoli, and on the lakes under Perry and Chauncey in the war of 1812, where he commanded a boat expedition which captured two English brigs. In Perry's great victory, Elliott commanded the *Niagara*. He succeeded Perry in command on the lakes; in 1815, he was in the Mediterranean squadron; was commissioner to select sites for dockyards, light-houses, and fortifications on the North Carolina coast; and later, commanded the *Constitution* in the Mediterranean. His conduct did not meet with approbation, and he was tried by court-martial and suspended for four years. A portion of the sentence was remitted, and he was made commandant of the Philadelphia navy-yard in 1844.

ELLIOTT, ROBERT WOODWARD BARNWELL, D.D., b. S. Car., 1840; son of Bp. Stephen; graduated from S. Car. coll., 1861; was ordained priest in the Prot. Epis. church, 1871. He had charge of mission stations in Ga.; was assistant minister of the church of the Incarnation, and of the chapel of the Reconciliation, New York; was rector of St. Philip's church, Atlanta, Ga.; was consecrated missionary bp. of Western Texas, 1874, and died Aug., 1887.

ELLIOTT, STEPHEN, LL.D., 1771-1830; b. S. C.; a botanist; graduate of Yale. He was instrumental in establishing the literary and philosophical societies of South Carolina, and was their president. He also assisted in establishing the state medical college, of which he was one of the faculty. He published *The Botany of South Carolina and Georgia*. He was for a time the editor of *The Southern Review*.

ELLIOTT, STEPHEN, D.D., 1806-66; son of the botanist; b. S. C.; graduate of Harvard; a lawyer until 1833; ordained in the Protestant Episcopal church, 1836. Soon afterwards he was appointed professor of sacred literature in South Carolina college. In 1840, he was chosen Protestant Episcopal bishop of Georgia.

ELLIOTT, WILLIAM, 1788-1863; b. S. C.; studied at Harvard; was in both branches of the legislature of his state, and in 1832 resigned rather than support nullification. He published *Fiesco*, a tragedy; *Carolina Sports by Land and Water*; and many political letters and essays.

ELLIPSE is the name of a figure in geometry, important from its being the approximate shape of the planetary orbits. It is a curve of the second order, and is a conic section, formed by cutting a right cone by a plane passing obliquely through its opposite sides. It may be defined as a curve, the sum of the distances of every point in which from two fixed points within the curve is always the same. These two fixed points are called the foci; and the diameter drawn through them is the major axis; the minor axis bisects the major at right angles. The distance of either focus from the middle of the major axis is the *eccentricity*. The less the eccentricity is compared with the axis, the nearer the figure approaches to a circle; and a circle may be considered as an E. whose foci coincide.

There are various contrivances for describing an E., called ellipsagraphs or *elliptic compasses*. The simplest method of description is to fix on a plane the two ends of a thread with pins in the foci, and make a pencil move on the plane, keeping the thread constantly stretched. The end of the pencil will trace an E., whose major axis is equal to the length of the thread.

The equation to an E. (see CO-ORDINATES), referred to its center as origin, and to its major and minor axes as rectangular axes, is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, where a and b are the semi-major and semi-minor axes respectively. From this equation, it may be shown, by the integral calculus, that the area of an E. is equal to πab ; or is got by multiplying the product of the semi-major and semi-minor axis by 3.1416. It may also be shown that the length of the circumference of an E. is got by multiplying the major axis by the quantity $\pi \left(1 - \frac{d^2}{2^2} - \frac{3d^2}{4^2} - \frac{3^2 \cdot 5d^2}{2^2 \cdot 4^2 \cdot 5^2} - \text{etc.}\right)$, where $d = \frac{1-4b^2}{4a^2}$.

ELLIP'SIS (Gr. omission) is a term used in grammar and rhetoric, to signify the omission of a word necessary to complete the expression or sentence in its usual form. The object of E. is shortness and impressiveness; accordingly, it prevails in proverbs. Ellipses are used in all languages, but the same forms of ellipses are not common to all. Thus, "the house we saw," instead of "the house *that* we saw," is a kind of E. peculiar, so far as we know, to English.

ELLIP'SOID is a surface of the second order, of which the spheroid (q.v.) is a species, and the most interesting, from the fact of the form of the earth being spheroidal. The equation to an E. referred to its center and rectangular co-ordinates is $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$.

ELLIPTICITY (of the earth). See EARTH.

ELLIS, a co. in w. Kansas, drained by Saline and Smoky rivers, and crossed by the Union Pacific railroad; 625 sq.m.; pop. '90, 7942. It is mostly prairie, and the soil is fertile. Co. seat, Hays.

ELLIS, a co. in n.e. Texas, on Trinity river, intersected by the Houston and Texas Central railroad; 969 sq. m.; pop. '90, 31,774, includ. colored. The surface is undulating, with plenty of timber; soil fertile, producing corn, cotton, wheat, etc. Co. seat, Waxahachie.

ELLIS, ALEXANDER JOHN, F.R.S., F.S.A., was b. at Hoxton in 1814, and educated at Shrewsbury, Eton, and Trinity college, Cambridge, taking his B.A. degree in 1837. His name by birth was Sharpe, which was changed by royal license in 1825. He was elected a fellow of the royal society in 1864, and of the society of antiquaries in 1870. He was president of the philological society during 1872-74, and was a member of the philosophical and mathematical societies of London. Among his numerous and valuable works may be noted: *Alphabet of Nature* (1845); *Essentials of Phonetics* (1848); *Universal Writing and Printing* (1856); *Early English Pronunciation* (1869-71); *Practical Hints on the Quantitative Pronunciation of Latin* (1874); translation of and several appendices to Helmholtz's *Sensations of Tones as a Physiological Basis for the Theory of Music* (1875). He d. in 1890.

ELLIS, GEORGE EDWARD, D.D.; b. Boston, 1814; graduate of Harvard and of Cambridge divinity school; in 1840, Unitarian pastor in Charlestown, Mass.; resigning in 1869; in 1857, professor of doctrinal theology in the Cambridge divinity school. In 1864 he delivered the Lowell lectures on the evidences of Christianity. He wrote lives of John Mason, Anne Hutchinson, and William Penn, for Sparks's *American Biography*; and published the *Half Century of the Unitarian Controversy*; *The Aims and Purposes of the Founders of Massachusetts*; and various memoirs and biographies. For several years he was editor of the *Christian Examiner*. He d. in 1894.

ELLIS, SIR HENRY, English antiquary, was born in London in 1777, was educated at Merchant Taylor's School, and at St. John's College, Oxford, of which he became a fellow. He held a sub-librarianship in the Bodleian at Oxford for a few months and was then (1800) appointed to a similar post in the British Museum. He was chief librarian from 1827 to 1856, when he retired. In 1833 he was knighted by William IV. He edited Brand's *Antiquities* (1813), and published *Original Letters Illustrative of English History* (1824-46); *Introduction to Domesday Book* (1833); and works on the Townley and Elgin marbles. He d. in 1869.

ELLIS, ROBINSON, Latinist, was born in Barming, England, in 1834. He was educated at Rugby, and at Balliol college, Oxford, winning a fellowship at Trinity in 1858. In 1866, he published tentatively a small edition of Catullus, and in 1867 the large edition, which is one of the monumental works of English classical scholarship. In 1871, he put forth a metrical translation of the same poet, which was favorably received. He was called to the chair of Latin in University College, London, in 1870, and was for a time university reader in Latin literature at Oxford. In 1881 he published an edition of Ovid, and 1889 a second edition of his Catullus. In 1893 he became Professor of Latin at Oxford.

ELLIS, WILLIAM, an eminent English missionary, was b. August 29, 1794. In Jan., 1816, he sailed with his wife for the South Sea islands, as a missionary of the London missionary society, and labored there for nearly ten years. He set up in Tahiti the first printing-press in the South Sea islands. In 1824, he returned to England, on account of the illness of his wife. He was for some years employed at home in the business of the London missionary society. In 1826, he published a *Narrative of a Tour through Owhyhee*; and in 1829, *Polynesian Researches*, 2 vols. In 1839, he published a *History of Madagascar*, 2 vols., compiled from government papers, and information received from missionaries. In 1835, his wife died, and two years afterwards he married Miss Sarah Stickney, who for many years conducted a school for girls at Hoddesdon, in Hertfordshire, and who is well known as the authoress of many popular works, among which are *The Women of England* (1838), *The Daughters of England* (1842), *The Wives of England* (1843), *Hearts and Homes* (1848-49), and *The Mothers of Great Men* (1859). Her works are all of an excellent moral and religious tendency, and have been very widely circulated both in Britain and America. She was educated among the Society of Friends, to which her parents belonged.—In 1853, Mr. E. was sent to Madagascar by the London missionary society, to inquire into the state of things in that island, and particularly into the condition and prospects of the Christians there. In 1859, he published an interesting and valuable work, entitled *Three Visits to Madagascar, during 1853-56, with Notices of the People, Natural History, etc.*, a work to which we are largely indebted for our present information concerning that island. In his *Polynesian Researches*, as well as in this work, Mr. E. gives much information concerning the inhabitants, scenery, and productions of the countries which he visited, and few works of greater general interest or higher value have come from the pens of modern missionaries. In 1867, he published another work, the nature of which appears from its title, *Madagascar Revisited, describing the Events of a New Reign, and the Revolution which followed, setting forth also the Persecutions endured by the Christians, and their Heroic Sufferings, with Notices of the Present State and Prospects of the People*. He died in 1872.

ELLISTON, ROBERT WILLIAM, a distinguished English actor, was born in London in April, 1774, and was the son of a watchmaker. He was educated at St. Paul's school at the expense of an uncle, but ran away from home in 1791, and joined a theatrical company at Bath, making his first appearance, in a minor part, in that same year. In 1793 he was highly successful as Romeo; in 1796 appeared in London at the

Haymarket and Drury Lane. From 1804 to 1809 he was a member of the Drury Lane company, but after the theatre was burned, opened the Surrey theatre, returning to Drury Lane in 1812, where he took leading parts, withdrawing in 1815 after some experience as a provincial manager. He became lessee and manager of Drury Lane in 1819, but retired a bankrupt in 1826. Subsequently he played at the Surrey theatre, but his dissipated habits of long standing prevented him from regaining his old prestige, and he died of apoplexy, July 7, 1831. Elliston ranked among the great tragedians of his time and was no less remarkable as a comedian. Charles Lamb praised him enthusiastically and Leigh Hunt considered him the best lover on the stage both in tragedy and comedy. Amusing stories are told of his versatility and his self-conceit. See *Life*, by Raymond (2 vols. 1849).

ELLO RA, a decayed t. in the dominions of the Nizam, not far from the city of Dowlatabad, in lat. $20^{\circ} 2' N.$, and long. $75^{\circ} 13' E.$ It is celebrated for its wonderful rock-cut temples. Their number has not been precisely ascertained, but Erskine reckoned 19 large ones, partly of Hindu and partly of Buddhist origin. Some are cave-temples proper—i.e., chambers cut out in the interior of the rock—but others are vast buildings hewn out of the solid granite of the hills, having an exterior as well as an interior architecture, and being, in fact, magnificent monoliths. In executing the latter, the process was, first to sink a great quadrangular trench or pit, leaving the central mass standing; and then to hew and excavate this mass into a temple. The most beautiful of these objects is the Hindu temple, Kailasa. At its entrance, the traveler passes into an antechamber 138 ft. wide by 88 deep, adorned by numerous rows of pillars. Thence he proceeds along a colonnade over a bridge into a great rectangular court, which is 247 ft. in length and 150 broad, in the center of which stands the temple itself, a vast mass of rock richly hewn and carved. It is supported by four rows of pilasters, with colossal elephants beneath, and seems suspended in the air. The interior is about 103 ft. long, 56 broad, and 17 high, but the entire exterior forms a pyramid 100 ft. high, and is overlaid with sculpture. In the great court are numerous ponds, obelisks, colonnades, sphinxes, and on the walls thousands of mythological figures of all kinds, from 10 to 12 ft. in height. Of the other temples, those of Indra and Dumarheyna are little inferior to that of Kailasa. Regarding their antiquity and religious significance, authorities are not agreed; but at all events they must be subsequent to the epic poems *Ramayana* or *Mahabharata*, because they contain representations taken from these poems, and also to the cave-temples at Elephanta, because they exhibit a richer and more advanced style of architecture.

ELLORE, a t. of the district of Godavari, in the province of Madras, stands in lat. $16^{\circ} 42' N.$, and long. $81^{\circ} 10' E.$ According to the census of 1891, the pop. of E. was 29,400. E. was formerly an important military station, and has at present carpet manufactures. The town occupies both banks of the Jummulair, a torrent of the eastern Ghauts, which, instead of reaching the bay of Bengal, loses itself 3 m. further down, in the landlocked Colair lake. In fact, for about 50 m. to the westward of the sea, the neighboring country is depressed below the level of the maritime belt, the stagnant pool above mentioned not only having independent feeders of its own, but also receiving supplies, in the season of high-water, from the Kistnah or Krishna, and the Godavery. Under such circumstances, the climate of E. is at once unpleasant and unhealthy. During the s.w. monsoon, bringing with it, of course, the accumulated heats of the whole breadth of the peninsula, the temperature is more particularly oppressive, having been known to rise, in the night, to $120^{\circ} F.$

ELLSWORTH, a co. in central Kansas, on Smoky River, crossed by the Union Pacific and the St. Louis and San Francisco railroads; 720 sq. m.; pop. '90, 9272. The surface is nearly all prairie and the soil fertile, producing corn, wheat, etc. Co. seat, Ellsworth.

ELLSWORTH, a city, port of entry, and co. seat of Hancock co., Me.; on both sides of the Union river, 30 miles southeast of Bangor. It has an extensive trade in lumber and ice, a large number of vessels engaged in the cod and mackerel fishery, and manufactures of lumber, furniture, blinds, shoes, carriages and sleighs, sails and iron and brass. Several bridges cross the river at this point. The principal public buildings are a court house, custom house, high school, and public library. There are national and savings banks, building and loan association, and weekly newspapers. Pop. '90, 4804.

ELLSWORTH, EPHRAIM ELMER, b. N. Y., 1837; killed May 24, 1861, at Alexandria, Va. Before the civil war he organized a company of zouaves, with which he traveled in different parts of the country, in the summer of 1860, winning great praise by the perfection of their drill. In April, 1861, he organized a zouave regiment from the volunteer firemen of New York city. His regiment took part in the first advance of the national forces from Washington into Virginia. Ellsworth, as they entered Alexandria, went into a hotel to take down a secession flag which was flying from its roof, and while coming out it was met and shot dead by the landlord, who the next moment was also dead—killed by Ellsworth's soldiers.

ELLSWORTH, OLIVER, LL.D., 1745-1807; b. Conn.; graduated at the college of New Jersey in 1766, and began the practice of law at Hartford. He was a member of

the Connecticut general assembly, and in 1777, a delegate to Congress. From 1780 to 1784, he was a member of the council of Connecticut, and in the latter year was appointed judge of the superior court. In 1787, he was sent as a delegate to the convention which framed the first constitution of the United States. He was one of the first U. S. senators from Connecticut, and at the end of his term was nominated by Washington chief-justice of the U. S. supreme court. After five years' service he resigned; but in the mean time he was sent to France as one of the commissioners to negotiate a treaty with that nation. Returning to Connecticut, he was chosen chief-justice of the supreme court, but declined to accept the place.

ELLSWORTH, WILLIAM WOLCOTT, LL.D.; 1791-1868; son of Oliver; b. Conn.; graduate of Yale, and professor of law in Trinity college. He was judge of the supreme court of the state from 1847 to 1861, a member of congress in 1829, and governor of Connecticut in 1838-42.

ELL'WANGEN, a t. in Württemberg, 55 m. n.e. of Stuttgart; a place of considerable importance in manufacturing; pop. '90, 4606. It is the seat of government of the circle of Jaxt.

ELLWOOD, THOMAS, 1639-1713; an English author noted for his intimacy with Milton, whom he met through an introduction by a Quaker family, and to whom he became reader of Latin. Ellwood had become a Quaker, to his father's great disgust, and with the result of bringing upon himself much persecution. Milton gave Ellwood the manuscript of *Paradise Lost* to read, and asked his opinion of it. In returning it, Ellwood suggested *Paradise Found* as a subject; and this, as Milton long afterward said, suggested to his mind the supplementary poem of *Paradise Regained*. It may be the general opinion that it would have been as well for the great poet if Ellwood had kept his idea to himself. Ellwood was the author of a number of polemical works, among them *Forgery no Christianity*; *The Foundation of Tithes Shaken*; and *Sacred Histories of the Old and New Testaments*, and an autobiography, 1714.

ELM, *Ulmus*, a genus of trees of the natural order *ulmaceæ*, natives of temperate climates, with serrated leaves unequal in their two sides, and small flowers growing in clusters appearing before the leaves, and containing 4 to 12 stamens and one germen. The fruit is a samara, or compressed one-seeded little nut, winged all around. One of the most important species is the COMMON SMALL-LEAVED or ENGLISH ELM (*U. campestris*), a tree of 60 to 80 ft. in height, with ovato-elliptic, doubly serrated leaves, and flowers almost destitute of stalks. The wood is compact, and very durable in water. The tree is diffused all over Europe; is found also in the w. of Asia and n. of Africa, and is used for a great variety of purposes by wheelwrights, machine-makers, ship and boat builders, etc.; it is also prized by joiners for its fine grain, and the mahogany color which it readily assumes on the application of an acid. It is reckoned superior to the wood of any other species of elm. The bark is used in dyeing and in sugar-refining, and, in times of scarcity, has been used in Norway for grinding into meal and mixing in bread, which has a less disagreeable taste than that made from meal mixed with fir-bark. The inner bark is used medicinally in cutaneous diseases; it is mucilaginous, and has a bitter astringent taste. The ELM BALSAM (*beaume d'orme*), which was formerly in great repute, is a brownish substance, which is found in dried galls of the leaves in the s. of Europe, Persia, etc. From these galls, in an earlier stage, flows a clear, viscid, sweetish liquid, called elm water (*eau d'orme*), which is used for washing wounds, contusions, and sore eyes.—The seeds of the E. are eagerly eaten by pigeons and common poultry. The E. is one of the principal timber trees of Britain, most extensively planted, and a chief ornament of English scenery.—The CORK-BARKED ELM (*U. suberosa*), by many regarded as a variety of *U. campestris*, is distinguished by the corky wings of the bark of the branches. It is a taller and more spreading tree, with much larger leaves. It is a European tree, common in plantations in Britain, but a doubtful native.—The DUTCH CORK-BARKED ELM (*U. major*) is also looked upon by many as a variety of *U. campestris*. It is still more corky in its bark, and has still larger leaves. It is of very quick growth, but the wood is very inferior.—The BROAD-LEAVED or WYCH ELM (*U. montana*) is the only species that can with certainty be regarded as indigenous to Scotland. It has rough and broad leaves, a stem less upright than the English E., and large spreading branches. The wood is used for all the purposes of the English elm. The tree is of very quick growth. Protuberances of gnarled wood are not unfrequently produced, which are finely knotted and richly veined; they are much esteemed for veneering, and are sometimes very valuable. Varieties of this species are known as the GIANT ELM and CHICHESTER ELM.—The SMOOTH-LEAVED ELM (*U. glabra*) is by some regarded as a variety of *U. montana*, but is distinguished, besides other characters, by smooth leaves, which are much smaller. It is a native of England. A variety called the HUNTINGDON ELM is much esteemed.—The CORNISH ELM (*U. stricta*), found in the s.w. of England, is remarkable for its rigid, erect, and compact branches.—Very different is the habit of *U. effusa*, a continental species with a large spreading head and smooth bark, distinguished also by the long stalks of its flowers and its ciliated fruit. See illustration, HAZEL, etc., vol. VII., fig. 12.—The AMERICAN or WHITE ELM (*U. Americana*), which attains its loftiest stature between lat. 42° and lat. 46°, is a magnificent tree, sometimes 100 ft. in height, the trunk reaching 60 or

70 feet before it separates into branches, and the widely diffused pendulous branches floating gracefully in the air; but the timber is not much esteemed.—The RED or SLIPPERY ELM (*U. fulva*) is also common in the basin of the Mississippi as far s. as lat. 30°, and in western Canada and New England. It attains a height of 50 or 60 feet. The wood is more valuable than that of the last species, but much more inferior to the English elm. The leaves and bark yield an abundant mucilage, which is bland and demulcent, and esteemed a valuable remedy in catarrh, dysentery, and other complaints.—The WAHOO or WINGED ELM (*U. alata*) is a small tree, found from lat. 37° to Florida, Louisiana, and Arkansas, remarkable for the branches being furnished on two opposite sides with wings of cork. The wood is fine-grained, compact, and heavy. The CORKY WHITE ELM (*U. racemosa*) ranges from western New England to Wisconsin and southwards. Another species (*U. floridiana*) is found in Western Florida.—*U. chinensis* is a Chinese species of E., the leaves of which bear galls used in tanning and dyeing.

The name SPANISH ELM is given in the West Indies to a tree also called Bois DE CHYPRE, *cordia gerascanthus*, of the natural order *cordiaceæ*, the timber of which is valuable; also to *hamelia ventricosa*, of the natural order *rubiaceæ*, the timber of which is known to cabinet makers as prince-wood.

EL MAHDI. See MAHDI, EL.

ELMET, a small kingdom in ancient Britain, situated between Leeds and York, which retained its independence till it was conquered by Edwin, and annexed to Northumbria, abt. 625.

ELMINA, a fortified t. and seaport of West Africa, formerly capital of the Dutch settlements on the Gold Coast, is situated in an undulating and thickly wooded district, in lat. 5° 10' n., and long. about 1° 40' west. A few miles to the e. is Cape Coast Castle. E. was established by the Portuguese in 1481, and was the first European settlement on the coast of Guinea. It was taken by the Dutch in 1637, and four years after was ceded to them by Portugal. It was ceded to the British in 1872, and destroyed by them in 1874, during the Ashantee war. Pop. estimated at 10,530.

ELMIRA, city and co. seat of Chemung co., N. Y., on Chemung river, near the mouth of Newtown creek, and 57 m. w. of Binghamton. It was settled about 1790 and was chartered as a city in 1864. During the civil war it was a recruiting station and a depot for Confederate prisoners. It is entered by the New York, Lake Erie and Western, the Northern Central, the Delaware, Lackawanna and Western, the Tioga, and the Lehigh Valley railroads. It is attractively situated in a fertile region, and has Grove, Wisner, and Eldridge parks, Elmira College, Elmira Free Academy, Steele memorial library, Arnot-Ogden memorial hospital, Elmira Industrial School, Southern Tier Orphan Home, Home for the Aged, Y. M. C. A. building, Masonic Temple, a state reformatory, over thirty churches, several banks and a savings institution, electric lights and street railways, water works, and daily, weekly, monthly and quarterly periodicals. There are extensive car works, iron and steel rolling mills, and manufactories of boilers, steam engines, edge tools, steam fire engines, leather, flour, shoes, cigars, beer, bridges, woolen goods, glass, knit goods, etc., valued in 1890 at \$8,844,936. Pop. '70, 15,683; '80, 20,541; '90, 30,893.

ELMIRA COLLEGE, at Elmira, N. Y.; was founded at Auburn in 1852 as the Auburn Female University; went to Elmira the next year. It was long the only college in New York that offered advanced education exclusively to women. Five of the principal religious denominations must be represented on the board of trustees. The main building was erected in 1855. The Gillett memorial building was given to the college for a music school. There are two courses, the classical and the scientific, with the same requirements for admission. President, Rev. A. C. Mackenzie, D.D. There were in 1896, 14 instructors and 158 students, including 60 students of music.

ELMORE, a co. in central Alabama, intersected by the Coosa and bounded by the Tallapoosa river; 652 sq. m.; pop. '90, 21,732, includ. colored. Co. seat, Wetumpka.

ELMORE, a co. in s. western Idaho, bounded on the south by Snake river; formed from part of Alturas; 3000 sq. m.; pop. '90, 1870. Co. seat, Mountain Home.

ELMO'S FIRE, St., is the popular name of an appearance sometimes seen, especially in southern climates during thunder-storms, of a brush or star of light at the tops of masts, spires, or other pointed objects. It is sometimes accompanied by a hissing noise, and is evidently of the same nature as the light caused by electricity streaming off from points connected with an electrical machine. See ELECTRICITY. The phenomenon, as seen at sea, was woven by the Greeks into the myth of Castor and Pollux; and even yet such lights at the mast-head are considered by sailors a sign that they have nothing to fear from the storm.

ELMSHORN, a t. in the Prussian province of Schleswig-Holstein, 20 m. n.w. of Hamburg, is situated on both banks of the Krückau, a navigable stream, and feeder of the Elbe. Large numbers of boots and shoes are made at E. Pop. '90, 9533.

EL OBEID. See IL OBEID.

ELOCUTION (Lat. speaking out), the art of effective speaking, more especially of public speaking. It regards solely the utterance or delivery; while the wider art of oratory, of which E. is a branch, takes account also of the matter spoken. The art of E. held a prominent place in ancient education, but has been greatly neglected in modern times. See READING AND SPEAKING.

ÉLOGE. When a member of the French *académie* dies, it is customary for his successor to deliver an oration, setting forth his merits and services. This is called an *éloge* (Lat. *elogium*, Gr. *eulogia*, praise), and a considerable branch of French literature goes by the name. Many of the French *éloges* are mere florid panegyrics; but others, particularly those written by Thomas, D'Alembert, Bailly, Condorcet, Cuvier, and other eminent savants, are interesting and valuable biographies. The proper epoch of the *éloge* began with Fontenelle (2 vols., Par. 1731), who was distinguished for clearness, ease, and elegance. His successors have tried to outshine him in pomp of language.

ELOHIM, Hebr., plural of *Eloah*, Arab. *Ilāh*, Chald. *Elāh*, Syr. *Alōh*, might, power; in plur., intensified, collective, highest power—great beings, kings, angels, gods, *Deity*. As a *pluralis excellentie* or *majestatis*, and joined to the singular verb, it denotes, with very rare exceptions, *the One*, true God. Joined to the plural verb, however, it usually means gods in general, whether including the *One* or not. It is mostly used (in the singular sense) for or together with *Jehovah* (the Everlasting One); but some portions of the Scriptures employ exclusively either the one term or the other. This circumstance has given rise to endless discussions, and has also suggested amongst others the notion of different authors of Genesis. On this, and on the relation of those two words to each other, see the article **JEHOVAH**. We shall only mention here the hitherto unnoticed opinion of the Talmudists, that *E.* denotes the Almighty under the aspect of a God of strict justice; *Jehovah*, of clemency and mercy. As important for the history of the word *E.*, we may add, in conclusion, that it was very probably Petrus Lombardus who first tried to prove the Trinity out of this plural form—an attempt which, although unanimously and scornfully rejected by all scholars, from Calvin, Mercerus, Calixtus, the younger Buxtorf, etc., to our times, has lately been revived by Rudolf Stier, who has gone so far as to invent a new grammatical term, "*Pluralis Trinitatis*," for this purpose. See also the articles **SHEMITIC PLURAL** and **PENTATEUCH**.

ELOHIST AND **JEHOVIST**, terms adopted by a school of scriptural criticism which regards the Pentateuch as gathered from two sets of documents, in one in which the Deity appears under the name of "*Elohim*" (a plural form of "*Eloah*," *i.e.*, "*the mighty one*"); the other in which the Deity is called "*Elohim-Jahvé*" (the Massorets and later Jews substituted the vowels of "*adonai*," *i.e.*, "*the Lord*," for the proper vowel pointing of the Hebrew word represented by "*Jahvé*," or "*Yahvé*," regarded by them as "*an unspeakable word, which is usually translated 'I am that am,' thus giving the form 'Jehovah'*"). According to this school, the author of the Pentateuch, while rejecting polytheism, though retaining for the Deity, wherever he found it, the word "*Elohim*," compiled his work from two parallel traditions current among the earliest Semitic tribes. The Jehovist tradition is supposed to be older than the Elohist. Gen. i, and Gen. ii, 1-3, are supposed to be Elohist, but the rest of Gen. ii, with iii, iv., Jehovist. The late François Lenormant, a believer in inspiration and revelation, between which, however, he distinguished, held to this theory, as do Prof. Robertson Smith and many other scholars. By some of equal eminence it is stoutly opposed.

ELON, a district, with village of same name, in Amherst co., Va. Pop. '90, 4499.

ELONGATION, **ANGLE OF**, is the angle measuring the distance between two stars, as seen from the earth. Usually it is employed only in speaking of the distance of planets from the sun; the word "*distance*" being used instead of the word *E.*, in regard to fixed stars and planets, as related to one another.

ELOQUENCE is the oral or written expression of thoughts and truths in a manner adapted to convince or persuade hearers or readers, and excite them to corresponding action. In its highest form it is inspired by an earnest love of truth and right, and a hearty scorn for whatever is base and false. See **RHETORIC**.

ELOQUENT DOCTOR, **THE**, Doctor Facundus, a title given to Peter Aureolus, archbishop of Aix, in the fourteenth century.

EL PASO, a co. in central Colorado on the head-waters of the Arkansas river, intersected by the Denver and Rio Grande, and other railroads; 2660 sq. m.; pop. '90, 21,239. the surface is rough and the soil fertile; productions, chiefly agricultural, but valuable gold fields have recently been opened up at Cripple Creek. Pike's Peak, so long known as a guide for travelers over the plains, is one of its features. Co. seat, Colorado Springs.

EL PASO, the extreme w. co. of Texas, on the Rio Grande, and the New Mexico border; 8460 sq. m.; pop. '90, 15,678, includ. colored. Nearly the whole of the co. is sandy and barren, but there is some moderately good soil along the valley of the Rio Grande. Co. seat, El Paso.

EL PASO (Sp. "*the passage*"), city, port of entry, and co. seat of El Paso co., Tex.; on the Rio Grande, a little below a gap in the mountain through which that river flows, and at the junction of the Southern Pacific, Texas and Pacific, Atchison, Topeka and Santa Fé and Mexican Central railroads. It is 712 miles from Austin and 1209 miles from New Orleans, and is the chief thoroughfare between New Mexico and Chihuahua. Long an unimportant village, with a population in 1880 of only 736, it developed rapidly

after that date, and in 1890 had a population of 10,338. It has churches, schools, a \$200,000 Federal Building, several banks, and newspapers, a brisk business in grain and wool, an ore-smelting establishment, and varied manufactures. In the calendar year 1896, the imports aggregated \$7,110,117; exports, \$4,833,885, mostly gold and silver bullion.

EL'PHIN, a bishop's see in Ireland, united to Kilmore in 1833.

ELPHINSTONE, The Honorable MOUNTSTUART, 1779-1859, an English statesman. He was sent when but 17 years old by the East India company to Calcutta, became assistant to the British resident at Poonah in 1801, and later to sir Arthur Wellesley, to whom he acted as aid on the outbreak of war, and after the war was appointed resident at Nagpore. In 1808, he was envoy to the Afghan capital, Cabul, and in 1811 resident at Poonah. On the renewal of hostilities in 1817, he assumed command of the English troops during the battle of Kirkee, and contributed largely to their success. He subsequently governed the conquered districts with remarkable force and considerateness, preserving the native customs and rights, so as to win the regard of his subjects, and strengthen British rule. In 1820-27, he was lieutenant-governor of Bombay, and drew up the Elphinstone code. He is regarded as the founder of state education in India. He was twice offered the governor-generalship of India, but declined. His last 30 years were devoted to study and authorship. He wrote *An Account of the Kingdom of Cabul and its Dependencies in Persia and India*, and a *History of India*. Both are standard authorities.

ELPHINSTONE, WILLIAM, a celebrated Scottish prelate, and founder of King's college, Aberdeen, was b. in the year 1430 or 1431. He was the son of William Elphinstone, rector of Kirkmichael, and archdeacon of Teviotdale, and, as the marriage of ecclesiastics was then prohibited, his birth was illegitimate. E. studied at the university of Glasgow, where he took his degree of M.A. at the age of 24, at the same time that he took priest's orders. He seems to have acted as his father's curate at Kirkmichael for four years, but being strongly attached to the study of law (he had practiced as an advocate in the church courts before this), he went to France in his 29th year, at the instigation of his uncle, Laurence Elphinstone, who supplied him with the means of studying at the most celebrated schools of the continent. E. so highly distinguished himself, that after three years he was appointed professor in the university of Paris, and afterwards at Orleans, which had then the highest reputation as a legal school. So greatly were his learning and talents appreciated, that the parliament of Paris used to ask his opinion on great questions. After a residence of nine years abroad, he returned to Scotland, and was made successively official-gen. of the diocese of Glasgow (1471-72), rector of the university (1474), and official of Lothian in 1478, "then probably," says Mr. Cosmo Innes (*Sketches of Early Scottish History*, Edin. 1861), "the second judicial office in the kingdom, which he filled for two years, sitting in parliament, and serving on the judicial committees, which formed the supreme civil jurisdiction in Scotland." His dignity, learning, and prudence now began to procure him universal respect. He was the principal member of a great embassy sent from Scotland to France, to settle certain disputes that had sprung up between the two countries, and threatened the stability of their ancient alliance. In this important affair, he was eminently successful. On his return, he was made bishop of Ross in 1481. In 1483, he was removed to the see of Aberdeen; and between this period and the death of James III. he was several times engaged in embassies to France, England, Burgundy, and Austria. For a few months before the death of that monarch, he held the office of chancellor of the kingdom. He lost this great office on the accession of James IV., but, says the authority already quoted, "he was speedily restored to favor, and to the royal councils, and seems to have been keeper of the privy seal from 1500 till his death." He did not suffer his office to withdraw him from the care of his diocese, where he applied himself to the faithful discharge of his episcopal functions, endeavoring to reform the clergy, the service, and the ritual of his church. He next concluded (while on a mission to the continent for another purpose) a treaty with Holland, which was beneficial to Scotland. E. seems to have had a genuine desire for the enlightenment and improvement of his countrymen. Whenever leisure permitted, we find him engaged in devising means to this end. It appears to have been chiefly through his influence that the first printing-press—that of Chepman and Miller—was established in Scotland. He superintended the preparation and printing of the *Breviary of Aberdeen*, and collected the materials for the lives of the Scottish saints contained in that work. He procured from the pope (Alexander VI.) a bull for erecting a university in Aberdeen. The bull was sent in 1494, but the college was not founded till 1500, when it was dedicated to St. Mary—a name afterwards changed to King's college. E. built also the great central tower and wooden spire of his cathedral church at Aberdeen, provided its great bells, covered the roofs of its nave, aisles, and transept with lead; and, at his own expense, built a stone bridge over the Dee for the benefit of his townsmen. The fatal battle of Flodden, 9th Sept., 1513, broke the spirit of E., who was never seen to smile after. He died 25th Oct., 1514, and was buried before the high altar of the chapel of the college which he founded. E. was a man of great vigor of mind and nobleness of nature—"one of those prelates," says a writer in the *Quarterly Review* (No. clxix., p. 141), "who in their munificent acts, and their laborious and saintly lives, showed to the Scottish church, in her

corruption and decay, the glorious image of her youth." "We know him," says Mr. Innes, "in the history of the time as the zealous churchman, the learned lawyer, the wise statesman; one who never sacrificed his diocesan duties to mere secular cares, but knew how to make his political eminence serve the interests of his church; who, with manners and temperance in his own person, befitting the primitive ages of Christianity, threw around his cathedral and palace the taste and splendor that may adorn religion, who found time, amidst the cares of state and the pressure of daily duties, to preserve the Christian antiquities of his diocese, and collect the memories of those old servants of truth who had run a course similar to his own; to renovate his cathedral service, and to support and foster all good letters, while his economy of a slender revenue rendered it sufficient for the erection and support of sumptuous buildings and the endowment of a famous university." Some volumes of notes made by E. when studying in the law schools, are preserved in the library of the university of Aberdeen. A transcript of Fordun's *Scotichronicon*, with some additions, in the Bodleian library at Oxford, was long erroneously ascribed to him. His *Breviarium Aberdonense*, printed in 1509-10, was reprinted in two vols. 4to at London in 1853.

EL ROSARIO, a small t. of the Mexican confederation in the state of Cinaloa, is situated about 35 m. e.s.e. of Mazatlan. It is important chiefly as being a commercial entrepôt between Mazatlan and the interior. Pop. 5,000.

ELSASS AND ELSASS-LOTHRINGEN. See **ALSACE**.

ELSBURG, LOUIS, M.D., 1836-85; b. in Iserlohn, Westphalen; d. New York. He was educated at the Philadelphia high school, and Jefferson med. coll., Philadelphia; was resident physician in Mt. Sinai hospital, New York. In 1859 he devoted himself exclusively to laryngology, and became prof. of throat diseases in the univ. of New York, which he relinquished for a similar position in Dartmouth coll. He was one of the founders of the Polyclinic institute, New York. Dr. E. was editor of *Archives of Laryngology*; and wrote *Throat and Voice*, and *Harmony, Sound, and Music*. He was the first to illustrate the character of undertones and the division of sound; and invented many instruments which are used almost exclusively in operations on the throat and ear.

ELSLINORE' (Dan. *Helsingör*), a t. and seaport of Denmark, on the island of Seeland, is situated on the western shore of the sound, and at its narrowest part, $3\frac{1}{2}$ m. w.s.w. of the town of Helsingborg in Sweden, and 24 m. n. of Copenhagen. Lat. $56^{\circ} 2' \text{ n.}$, long. $12^{\circ} 36' \text{ east.}$ The town, which has been in recent times considerably improved, is spacious, and consists of one long principal street, with several lateral branches. The cathedral, containing some fine tombs, many of them very old, may be considered as one of the most interesting edifices. At a short distance to the e. of E. are the castle and the fortress of Kronborg, the former a white stone building in the Gothic style, and the latter, a stronghold mounted with guns that command the sound in all directions. To the n.w. of E., and in its immediate vicinity, is the royal château of Marienlist, the pleasure-grounds of which, occupying the crest of a hill, are open to the public. From the grounds of Marienlist, magnificent views may be had of the sound, of Helsingborg, and of the plains of Sweden. The harbor of E., formed by a wooden pier, is accessible to ships of light draught. E. has a brisk foreign trade, and has, besides, manufactures of straw-hats, arms, sugar, brandy, etc., also cotton-printing and fisheries. The sound dues (q.v.) were collected here. Pop. '90, 11,082.

Saxo Grammaticus, a famous writer of the 12th c., was born here. Here Shakespeare laid the scene of his *Hamlet*, a perversion of history on the part of the great dramatist, as Jutland, not Seeland, was Hamlet's country. The vaults under the castle of Kronborg were supposed to be the residence of Holger Danske, the mythic hero of Denmark, who never appeared above ground save when the country was in danger, and was then supposed to march at the head of the Danish armies. In severe winters the sound is frozen over at E., so that one can walk over the ice from Denmark to Sweden.

ELSSLER, FANNY, a celebrated dancer, was b. at Vienna, June 23, 1810, and educated at Naples for the ballet, along with her elder sister Theresa. The first triumph of the sisters took place at Berlin, where they appeared in 1830. The reputation acquired by Fanny in Berlin preceded her to France, America, England, and St. Petersburg, where her beauty, amiability, and mastery in her art, charmed all classes of society. In 1841, the two sisters went to America, where they excited unwonted enthusiasm. After Fanny had earned laurels in St. Petersburg, she returned, in 1851, to Vienna, to take a final leave of the stage. She then retired to Hamburg, where she remained, till in 1854 she settled finally in Vienna. Theresa was less graceful in her motions than her sister, but exhibited great strength, boldness, and agility. On the 25th April, 1851, F. became the wife of Prince Adalbert of Prussia (who died in 1873), and was ennobled by the king of Prussia. She d. 1884.

ELSTER, the name of two rivers of Germany, the white and the black Elster. The white E. rises at the foot of the Elster mountains, on the n.w. boundary of Bohemia, flows in a northerly direction, and falls into the Saale 3 m. s. of the town of Halle,

in Prussia. Its chief affluent is the Pleisse, from the right. Length, about 120 miles. The black E. rises in the kingdom of Saxony, within 2 m. of Elstra, flows n.w., enters Prussia, and joins the Elbe 8 m. s.e. of Wittenberg. Length, 130 miles.

ELSTRACKE, REGINALD or RENOLD, an English engraver, who flourished about 1620. He worked chiefly for the booksellers, and his plates, which are executed with the graver, without etching, are almost entirely confined to portraits. Prints from his plates are much sought after, not only from their scarcity, and as illustrating English history, but as works of art, in which much character is expressed in a firm and forcible manner. When he did not sign his plates with his name, he marked them with his initials, R. E.

ELTON, a famous salt lake of Russia, is situated in the government of Saratov, 170 m. s.e. from the town of that name, the lat. of its center being 48° 56' n., and the long. 46° 40' east. Its longest diameter is 11 m., and its shortest about 9 miles. It has a superficial extent of 45,500 English acres, but at no place is it more than about 15 in. in depth. It is of an oval form, and can be easily reached from the s., but the northern bank rises so rapidly that access to it from that quarter is difficult. In the hottest season, so wonderful is the illusion produced by the crystallized salt, that the lake seems covered with snow and ice. Its annual yield of salt is estimated at over 1,000,000 cwt., in the collection of which large numbers of persons are employed.

ELUTRIATION (from the Latin word "to cleanse"), is an operation for preparing clay for porcelain manufacture, and for glazing earthenware, and for other purposes. Different forms of apparatus are used; some employ vats containing grinding wheels, others only wheels for stirring; but a simple deep vat or hogshead will answer the purpose on a small scale, the stirring being done by hand, with a rod or paddle. The earth or clay being mingled with sufficient water to make it quite thin, is stirred and allowed to stand, till the coarser particles are precipitated. The finer particles, suspended in the water, may then be drawn off (a siphon may be used with advantage), and after they have subsided, may be collected. The process for filtering water in reservoirs supplying cities by which it is made to pass over and under diaphragms, so that both light and heavy impurities are separated, is a process of filtration by elutriation. Elutriation on a grand scale is exhibited by nature in the deposit of fine earths. The immense beds of fine potter's clay and kaolin covering many square miles in area, are the result of the slow subsidence of fine particles suspended in water passing in a slow but steady current in estuaries. The streams from the land carry down the turbid products of rain, depositing at first coarse gravel, then finer gravel, then coarse and fine sand, all the particles pursuing an oblique descent, more and more approaching the horizontal, till at last the impalpable particles of fine clay are slowly deposited over vast areas.

EL VANS are veins of a granular crystalline mixture of felspar and quartz, probably proceeding from a granite mass, which are found in granite rocks and fossiliferous slates in Cornwall, Devon, and the s. of Ireland.

EL VAS, an episcopal city and fortress of Portugal, stands in a very fruitful district on the eastern frontier of the province of Alemtejo, 10 m. w. of Badajoz, and 40 m. n.e. of Evora. It is the strongest fortress in Portugal, and one of the strongest in Europe. It is built upon a precipitous hill; is surrounded by walls, and by a glacis and covered-way. Besides these, E. has other defenses in two formidable forts, fort Sta. Lucia, and fort Lippe, the former to the s., and the latter—almost entirely shell-proof—to the n. of the city. E. is an old town; many of its houses are badly built. Its most striking architectural feature is an enormous aqueduct, which conveys water to it from a distance of 3 miles. This aqueduct consists of four tiers of arches built upon one another, and rising to the height of about 250 feet. The chief manufactures of E. are arms and jewelry. Pop. 10,478.

E. has undergone many sieges. The Spaniards besieged it in 1385, and again in 1659, when a famous battle took place called the Lines of Elvas, in which the Portuguese, though greatly inferior in numbers, drove the Spaniards from their lines in front of the town. During the Peninsular War it was a place of great strategic importance and in 1808 was captured by the French under Marshal Junot. It was soon afterwards given up in accordance with the terms of the Convention of Cintra. E. was raised to the rank of a city by D. Manoel, king of Portugal, in 1513.

ELVES. See FAIRIES.

ELY, so called from a Saxon word, *clig*, an eel, or *helig*, a willow, may be called a cathedral town rather than a city, and is situated on an eminence in that part of the fen-country of Cambridgeshire called the *Isle of Ely*. Pop. '91, 8017. The Eastern Counties and the Great Northern railways have each stations, the former outside, the latter in the town.

Ely Cathedral.—About the year 673, Etheldreda, daughter of the king of East Anglia, and wife of Oswy, king of Northumberland, founded a monastery here, and took on herself the government of it. Two hundred years afterwards (870), the Danes ravaged the isle, and destroyed the monastery, which was rebuilt in 970 by St. Ethelwold, bishop

of Winchester; and this continued till 1081, when a new church was begun, which was converted into a cathedral, and the abbey erected into a see in 1109. The possessions of the abbey were divided between the bishop and the community. The cathedral contains some beautiful specimens of architecture, especially of early Norman. Its exterior dimensions are 535 ft. from w. to east. The great cross or main transept is 190 feet. The turrets of the w. tower are 215 ft. high, and the lantern over the central tower 170 feet. The w. front was built by Geoffry Ridel, the third bishop, who died in 1189, and is of Norman work. About 200 years after his time, an addition of 64 ft. was made to the tower, and over that a spire. This great superincumbent weight crushed the n.w. transept, and the s.w. one, which still remains, was considerably weakened. In front there is a w. portico or galilee (q.v.), of early Gothic, said to be the work of bishop Eustachius. The nave is of Norman work, and was completed about 1174. The columns are alternately round and octagonal. The roof was, in 1861, beautifully painted. The transepts, which are the most ancient parts of the church, were built in the reign of Henry I. They had originally a middle and two side aisles, but the latter are, in the s. transept, walled up, and the space used as a vestry and library. Originally there stood a square tower in the center of the building, opening into the nave and transepts; but this gave way in 1322, and fell eastwards, crushing three arches of the choir. The repair of this dilapidation was undertaken by the sacrist at that time, Alan de Walsingham. The design was original, an octagon tower with four longer and four shorter sides, surmounted by a lantern. The upper part of this, which is of timber, has recently been rebuilt.

The choir contains some rich varieties of decorated Gothic, and the fine shafts of Purbeck marble combine beautifully with the white stone-work. The whole has lately been restored and beautified. Originally, it was much shorter eastwards, and protruded into the nave, but in 1235 the semicircular end of the old church was taken down, and six arches added by Hugh de Northwold. At the dedication and removal of the relics, Henry III. and his court were present. The e. end is eminently beautiful: it consists of two tiers of high lancet-shaped windows. Perhaps the most interesting and yet beautiful part of the building is the Lady chapel—an incomparable work, irreparably spoiled by the barbarism of Puritan times. It was begun in 1321, and finished in 1349, simultaneously with the rebuilding of the central tower and ruined choir, a circumstance highly illustrative of the taste and munificence of the times. It has a stone roof, like King's college chapel in Cambridge, which it is supposed to have suggested, and the walls were once decorated from top to bottom with countless niches and images of saints and martyrs, not one of which remains undefaced. Its length is 100 ft.; width, 46; height, 60. Bishop Alcock's chapel, in which he lies buried, is at the e. end of the n. aisle—an overloaded specimen of the richest florid Gothic. Bishop West's chapel, at the e. end of the s. aisle, is a more pleasing example of the same style.

Amongst the celebrated names connected with E. are abbot Thurstan, who defended the isle against William the Conqueror for seven years; Longchamp, chancellor and regent under Richard I.; chancellor Morton, Simon Patrick, and bishop Andrews. The bishops of E., like the bishops of Durham, formerly enjoyed a palatine jurisdiction, and appointed their own chief-justice, etc.; but this privilege was taken from them by the 6th and 7th Will. IV. The bishop of E. is visitor to St. Peter's, St. John's, and Jesus colleges, Cambridge, of which last he also appoints the master. There is a grammar-school attached to the cathedral, founded by Henry VIII. There are some interesting remains of the old conventual buildings in the neighborhood of the cathedral.

ELY, ISLE OF, the s. part of the Bedford Level, or the part of Cambridgeshire n. of the Ouse. It includes above a half of this county, is 24 m. long from n. to s., with an average breadth of 14 m., and contains four hundreds.

ELY, RICHARD THEODORE, economist, b. Ripley, N. Y., in 1854; graduated at Columbia college in 1876; received degree of PH.D. at Heidelberg in 1879; professor of political economy at Johns Hopkins university in 1885-92; became director of the school of economics of the university of Wisconsin in 1892. In 1894 an unsuccessful attempt was made to depose him on a charge of having taught objectionable socialistic doctrines. His publications include *French and German Socialism* (1883); *Labor Movement in America* (1886); *Taxation in American States and Cities* (1888); *Political Economy* (1889); *Outlines of Economics* (1893); *Socialism: an Examination of Its Nature, Its Strength, and Its Weakness: with Suggestions for Social Reform* (1894), etc.

ELYMAIS, an ancient province on the Persian gulf, supposed to have been a district of Elam (q. v.), though the name is sometimes used as equivalent to Elam.

ELYRIA, village and co. seat of Lorain co., Ohio, on Black river, 7 m. s. of lake Erie, 25 m. w. of Cleveland, on the Lake Shore and Michigan Southern and the Cleveland, Lorain, and Wheeling railroads. There are churches, high school, public and law libraries, screw shears and other manufacturing, gas and electric lights, national bank, and weekly newspapers. Sandstone is exported. Pop. '90, 5611.

ELYSIUM (Gr. *elysion*), a place in the infernal regions of the ancient classical mythology, where the souls of the good dwell after death. In the *Odyssey*, Homer describes it as a place where the souls of the departed lived in ease and abundance among innocent pleasures, and enjoying a mild and wholesome air. In the *Iliad*, however, he gives a sombre view of the state of the departed souls. Achilles, though in E., is made to envy the life of the meanest hind on earth. By succeeding poets, the bliss of E. is drawn

in much more lively colors. Besides the amenity and various delights of the place, diverse employments are found for the inhabitants, according to the ruling passion of each while on earth. E. was supposed by some writers to be in mid-air, by others in the sun, by others in the center of the earth, next Tartarus, by others in the Islands of the Blest.

ELZEVIER', or ELZEVIR, the name of a celebrated family of printers at Amsterdam, Leyden, and other places in Holland, whose beautiful editions were chiefly published between the years 1583 and 1680. Louis, the first of them, is said to have been born at Louvain about the year 1540. He was induced by religious disturbances to leave his native city, and in 1580, he settled as a bookbinder and bookseller in Leyden, where he died about 1617. The first work edited by him bears the title *Drusii Ebraicorum Quæstionum ac Responsionum Libri Duo, videlicet Secundus ac Tertius, in Academia Lugdunensi MDLXXXIII. Veneunt Lugduni Batavorum apud Elsevirium e Regione Scholæ Novæ*. The second, a Eutropius by P. Merula, bears the date 1592, and was long erroneously believed to be the first that issued from E.'s press. Five out of Louis' seven sons continued to carry on their father's business. Their names were Matthew, Louis, Aegidius, Jodocus (Joost), and Bonaventura. The last, in conjunction with his nephew Abraham E. (a son of Matthew), prepared the smaller editions of the classics, in 12mo and 16mo, which are still valued for their beauty and correctness. It is mainly on these that their reputation is based. The house of E., in Amsterdam, was established by Louis, the son of Jodocus E., in 1638. Peter E., grandson of the last mentioned, carried on the bookselling business in Utrecht, and died in 1696. For more than a century, however, this family has ceased to have any connection with book-printing. It is believed that 1213 works in all proceeded from the E. presses. Amongst the most beautiful are the editions of Pliny, Virgil, Livy, Tacitus, and Cæsar; and, though for Greek and Hebrew texts the house of E. was surpassed by that of Stephens (q.v.), their Latin classics are unrivaled both for beauty and correctness. It is said that the Elzeviers generally employed women to correct the press, under the conviction that they would be less likely than men, on their own responsibility, to introduce alterations into the text. Compare Adry, *Notice sur les Imprimeurs de la Famille des Elzeviers* (Paris, 1806), and Pieter's *Annales de l'Imprimerie Elzévirienne* (1852); Willems, *Les Elzeviers* (Brussels, 1880).

EMACIATION (Lat. *macies*), leanness. See CONSUMPTION, TABES DORSALIS.

EMANATION means, in general, efflux or issue. In theology and philosophy, it indicates an ancient doctrine, which considered all things as emanating or flowing from a supreme principle. According to this doctrine, the origin of things is only an overflowing of the divine fullness—an outstreaming of the light from the necessity of its nature, and not any free action on the part of God. What is thus given off as a copy from original perfection, departs more and more from its source, and gradually degenerates, which was thought to account for the origin of evil. This doctrine came from the east, and pervades the Indian mythology, the system of Zoroaster, and the Neo-Platonic philosophy of Alexandria. In Christian theology, the idea of E. has been applied to explain the relation among the persons of the Trinity.

EMANCHÉ. See MANCH.

EMANCIPATION. See SLAVERY.

EMANCIPATION, in the Roman law, was the act by which the *patria potestas* (q.v.), or paternal authority, was dissolved in the life-time of the father. It took place in the form of a sale (*mancipatio*) by the father or the son to a third party, who manumitted him. The Twelve Tables required that this ceremony should be gone through three times, and it was only after the third sale that the son became *sui juris* under his own law. In general, the son was at last resold to the father, who manumitted him, and thus acquired the rights of a patron (q.v.), which would otherwise have belonged to the alien purchaser who finally manumitted him. In the case of daughters and grandchildren, one sale was sufficient. If the child died intestate, or if he required a tutor or curator, the father's rights as patron came into play; but if the father died intestate, the son took nothing, because he was out of his family. But this rigor of the old law was modified by the prætor's edict, which placed all the children on the same footing. In the law of Scotland, E. is called forisfiliation (q.v.). The only case in which the term is employed in England is with reference to poor-law settlements. See POOR; POOR-LAWS; REMOVAL OF PAUPERS; SETTLEMENT.

EMANCIPATION, CATHOLIC. See ROMAN CATHOLIC EMANCIPATION.

EMANCIPATION, PROCLAMATION OF. The document issued by Abraham Lincoln, president of the United States, Jan. 1, 1863, declaring the immediate freedom of the great majority of the slaves in the United States, and striking a death-blow at the whole system of American slavery in this country, for the purpose of putting an end to the civil war then existing in the slave states and restoring the union on the basis of equal liberty for all men. For a long time President Lincoln hesitated, on constitutional grounds, to take this step, which he held to be within the power of the executive only as a measure of war. At length, however, a crisis arrived when he felt it to be not only a right but a duty to destroy the institution in which the civil war had its roots, and

which had long been the great embarrassment and opprobrium of the republic. The document, in view of its purposes and effects, must ever hold an important place in the national annals.

PROCLAMATION.

Whereas, On the 22d day of Sept., in the year of our Lord 1862, a proclamation was issued by the president of the United States, containing among other things the following, to wit:

That, on 1st day of Jan., in the year of our Lord 1863, all persons held as slaves within any state, or any designated part of a state, the people whereof shall then be in rebellion against the United States, shall be thenceforward and forever free, and the executive government of the United States, including the military and naval authority thereof, will recognize and maintain the freedom of such persons, and will do no act or acts to repress such persons, or any of them, in any efforts they may make for their actual freedom:

That, the executive will, on the 1st day of Jan. aforesaid, by proclamation, designate the states and parts of states, if any, in which the people thereof respectively shall then be in rebellion against the United States, and the fact that any State, or the people thereof, shall on that day be in good faith represented in the congress of the United States by members chosen thereto at elections wherein a majority of the qualified voters of such state shall have participated, shall, in the absence of strong countervailing testimony, be deemed conclusive evidence that such state and the people thereof are not then in rebellion against the United States:

Now, therefore, I, Abraham Lincoln, president of the United States, by virtue of the power in me vested as commander-in-chief of the army and navy of the United States, in time of actual armed rebellion against the authority and government of the United States, and as a fit and necessary war-measure for repressing said rebellion, do, on this 1st day of Jan., in the year of our Lord 1863, and in accordance with my purpose so to do, publicly proclaim for the full period of 100 days from the day of the first above-mentioned order, and designate as the states and parts of states wherein the people thereof respectively are this day in rebellion against the United States, the following, to wit: Arkansas, Texas, Louisiana, except the parishes of St. Bernard, Plaquemines, Jefferson, St. John, St. Charles, St. James, Ascension, Assumption, Terre Bonne, Lafourche, St. Mary, St. Martin, and Orleans, including the city of New Orleans, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia, except the 48 counties designated as West Virginia, and also the counties of Berkeley, Accomac, Northampton, Elizabeth City, York, Princess Ann, and Norfolk, including the cities of Norfolk and Portsmouth, and which excepted parts are, for the present, left precisely as if this proclamation were not issued.

And by virtue of the power and for the purpose aforesaid, I do order and declare that all persons held as slaves within said designated states and parts of states are, and henceforward shall be, free; and that the executive government of the United States, including the military and naval authorities thereof, will recognize and maintain the freedom of said persons,

And I hereby enjoin upon the people so declared to be free, to abstain from all violence, unless in necessary self-defense, and I recommend to them, that in all cases, when allowed, they labor faithfully for reasonable wages.

And I further declare and make known that such persons of suitable condition will be received into the armed service of the United States to garrison forts, positions, stations, and other places, and to man vessels of all sorts in said service.

And upon this, sincerely believed to be an act of justice, warranted by the constitution, upon military necessity, I invoke the considerate judgment of mankind and the gracious favor of Almighty God.

In witness whereof, I have hereunto set my hand and caused the seal of the United States to be affixed.

Done at the city of Washington, this 1st day of Jan., in the year of our [L.s.] Lord 1863, and of the independence of the United States of America the 87th.

By the president:

ABRAHAM LINCOLN.

WILLIAM H. SEWARD, secretary of state.

The work of emancipation in the United States was completed at the adoption of article XIII. of the amendments to the constitution, and the reconstruction of the states in insurrection upon that basis. (See SLAVERY.)

EMANUEL, a co. in e. central Georgia, s.e. of Ogeechee river; 1028 sq. m.; pop. '90, 14,703, incl. colored. The surface is level and largely covered with pine forests; soil sandy, and not very productive. Cotton, corn, and pork are produced. Co. seat, Swainsboro.

EMANUEL I., King of Portugal, styled **THE GREAT**, and sometimes, likewise, **THE FORTUNATE**, was b. on the 3d May, 1469, and succeeded John H. in 1495. Before his accession to the throne, he bore the title of duke of Beja. On his accession, he prepared the code of laws which bears his name, and rendered himself remarkable by his zeal and exertions in the cause of education, by his active piety, and by his predilection for the society of artists and scholars. Through his exertions, Portugal became the

first naval power of Europe, and the center of the commerce of the world. He despatched Vasco da Gama to sail round the cape of Good Hope, and discover the passage to India. Cabral was commissioned by him to prosecute the discoveries of Vasco da Gama still further, and Corte Real to sail along the coasts of North America. The expeditions under Albuquerque put E. in possession of the s. coast of Africa and of the Indian archipelago. Not satisfied with this, he opened a communication with Persia, Ethiopia, and, in 1517, with China. At his death, 13th Dec., 1521, Portugal was in possession of a large fleet, strong fortresses, well-furnished arsenals, a warlike army, a flourishing trade and commerce, and extensive colonies. His reign has been termed the golden age of Portugal. E. was thrice married: first to Isabella, the daughter of Ferdinand; afterwards to Mary of Castile, her sister (by whom he had two children, John and Isabella, the former of whom succeeded him on the throne); and thirdly, to Eleanor of Austria, sister of Charles V.

EMARGINATE. See LEAVES.

EMBA, a river of Turkistan, in the Kirghiz territory, rises at the western base of the Muehajar or Mongol mountains, and flowing in a s.w. direction, enters the Caspian sea after a course of about 300 miles.

EMBALMING, the art of preserving the body after death, invented by the Egyptians, whose prepared bodies are known by the name of mummies, and are called in the hieroglyphs *sahu*, and by St. Augustine *gabbaroe*. This art seems to have derived its origin from the idea that the preservation of the body was necessary for the return of the soul to the human form after it had completed its cycle of existence of three or ten thousand years. Physical and sanitary reasons may also have induced the ancient Egyptians; and the legend of Osiris, whose body, destroyed by Typhon, was found by Isis, and embalmed by his son Anubis, gave a religious sanction to the rite, all deceased persons being supposed to be embalmed after the model of Osiris in the *abuton* of Philæ. The art appears as old as 4000 B.C., at least the bodies of Cheops, Mycerinus, and others of the age of the 4th dynasty having been embalmed. One of the earliest recorded embalmments on record is that of the patriarch Jacob; and the body of Joseph was thus prepared, and transported out of Egypt. The process has been described by Herodotus and Diodorus; but their accounts can only refer to their own age, and are only partially confirmed by an examination of the mummies. The following seems to have been the usual rule observed after death. The relations of the deceased went through the city chanting a wail for the dead. The corpse of a male was at once committed into the charge of the undertakers; if a female, it was retained at home till decomposition had begun. The *paraschistes*, or flank-inciser of the district, a person of low class, whose establishment was situated in the cemeteries or suburbs, conveyed the corpse home. A scribe marked with a reed-pen a line on the left side beneath the ribs, down which line the paraschistes made a deep incision with a rude knife or Ethiopian stone, probably flint. He was then pelted by those around with stones, and pursued with curses. Another kind of embalmer, the *taricheutes*, or preparer, then proceeded to remove the entrails and lungs, with the exception of the heart and kidneys. The brain was extracted by another taricheutes, by a crooked instrument, through the nose. All this having been effected, the body was ready for the salts and spices necessary for its preservation, and the future operations depended upon the sum to be expended on the task. When Herodotus visited Egypt, three methods prevailed: the first, accessible only to the wealthy, consisted in passing peculiar drugs through the nostrils into the cavities of the skull, rinsing the belly in palm-wine, and filling it with resins, cassia, and other substances, and stitching up the incision in the left flank. The mummy was then steeped in natron for seventy days, and wrapped up in linen, cemented by gums, and set upright in a wooden coffin against the walls of the house or tomb. This process cost a silver talent, which, considering the relative value of ancient money at one third of that at present, would amount to about \$3500. The second process consisted in removing the brain, as before, but only injecting the viscera with *kedrion*, or cedar oil, and soaking the corpse in a solution of natron for seventy days, which brought away or destroyed the viscera and soft portions, leaving only the skin and bones. The expense was a *mina*, relatively worth about \$1200. The third process, in use for the poorer classes, washed the corpse in myrrh, and salted it for seventy days. The expense was a trifle, not mentioned. When thus prepared, the bodies were ready for sepulture, but were often kept some time before being buried—often at home—and even produced at festive entertainments, to recall to the guests the transient lot of humanity. When buried, they were sent to the *cholchytæ*, a higher class than the *tarichsutæ*, who had charge of the tombs, the mummies, and the masses for the dead. All classes were embalmed, even malefactors; and those who were drowned in the Nile or killed by crocodiles received an embalmment from the city nearest to which the accident occurred. As the art, however, existed for many centuries, it may be easily conceived that mummies were preserved by very different means, and quite distinct from those described by classical authors, some having been found merely dried in the sand; others salted by natron, or boiled in resins and bitumen, with or without the flank incision, having the brains removed through the eyes or base of the cranium, with the viscera returned into the body, placed upon it, or deposited in jars in shapes of the genii of the dead, the skin

partially gilded, the flank incision covered with a tin plate, the fingers cased in silver, the eyes removed, and replaced. The mummies are generally wrapped in linen bandages, and placed in costly coffins. See *SARCOPHAGUS*. The sacred animals were also mummied, but by simpler processes than men. Mummies, it may be observed in passing, were used in the 15th and 16th centuries of the Christian era for drugs and other medical purposes, and nostrums against diseases, and a peculiar brown color, used at the background of pictures, was obtained from the bitumen. The Ethiopians used similar means to preserve the dead, and the successful nature of embalming may be judged from the numerous mummies in the different museums of Europe. Other less successful means were used by nations of antiquity to embalm. The Persians employed wax; the Assyrians, honey; the Jews embalmed their monarchs with spices, with which the body of our Lord was also anointed; Alexander the great was preserved in wax and honey, and some Roman bodies have been found thus embalmed. The Guanches, or ancient inhabitants of the Canary isles, used an elaborate process like the Egyptians; and desiccated bodies, preserved by atmospheric or other circumstances for centuries, have been found in France, Sicily, England, and America, especially in Central America and Peru. The art of embalming was probably never lost in Europe; and De Bils, Ruysch, Swammerdam, and Clauderus boast of great success in the art. There was a celebrated cabinet of M. De Rasière in 1727, containing prepared bodies; and the mode of embalming princes and others, by prepared balms and other substances, is detailed by Penicher, consisting in the removal and separate embalmment of the heart and viscera, and removing the brain, and introducing the preparations by incisions all over the body. Dr. Hunter injected essential oils through the principal arteries into the body. Boudet, during the French empire, embalmed the bodies of the senators with camphor, balsam of Peru, Jews' pitch, tan and salt; but the discovery of Chaussier of the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard, and grayish, introduced a new means of embalming by Beclard and Larrey; but owing to the desiccation the features do not retain their shape. The discovery of the preservative power of a mixture of equal parts of acetate and chloride of alumina, or of sulphate of alumina, by Bannal in 1834, and of that of arsenic by Tranchini, and of pyroxilic spirits by Babington and Rees in 1839, and of the antiseptic nature of chloride of zinc, have led to the application of these salts to the embalming or preparation of bodies required to be preserved for a limited time; but there is no reason to believe that bodies so preserved will last as long as Egyptian mummies. See Pettigrew, *History of Mummies* (4to, Lond. 1834); Gannal, *Traité d'Embaumement* (8vo, Paris, 1838), translated by Harlan (8vo, Philadelph. 1840). See *ill.*, *EGYPTIAN DEITIES*.

EMBANKMENT, EARTHWORK. Embankments, in engineering, are masses of earth, rock, or other materials artificially formed, and rising above the natural surface of the ground. They are chiefly formed either (1) to carry railways, common roads, canals, etc., over depressions of the country; or (2) for hydraulic purposes, such as the formation of reservoirs for storing water; or as defenses against the overflowing of rivers, the encroachments of the sea, of lakes, etc.

In the formation of canals, railways, and other roads, embankment and *excavation* go hand in hand, and, under the name of *EARTHWORK*, form—especially in modern times, and since the development of the railway system—a vast branch of industry, giving employment to many thousands of laborers, known in England as “navvies.”

In planning works of the kind alluded to, engineers follow, as much as possible, the principle of making the cuttings or excavations and the embankments balance; i.e., of making the earth, etc., taken from the cuttings be sufficient for the formation of the embankments. See *RAILWAYS (ENGINEERING)*. In proceeding to the actual construction of a railway embankment, e.g., a beginning is made at the points where the level of the formation meets the surface of the ground; and on each side of these points the cutting is taken out, and the embankment formed by men using pick, shovel, and barrow, so that a roadway is formed for a distance of from 50 to 100 yards. When the “lead,” or the distance between the face of the cutting and the “tip-head,” or end of the embankment, is greater than this, it is no longer economical to use the barrow. To continue the cutting and embankment, several methods may be employed; the most common are dobbin carts; small wagons run upon light rails at a narrow gauge, and drawn by men or horses; ordinary earth-wagons drawn by horses, and occasionally by a locomotive; and, lastly, ballast-wagons or trucks drawn by a locomotive. The cost of earthwork naturally varies greatly with the nature of the strata in which the cutting has to be made, the length of the “lead,” and other circumstances. When rocks have to be cut through, blasting (q.v.) is had recourse to. One of the points on which considerable doubt existed was as to the inclination of the side-slopes of embankments; but it has been found that nearly all kinds of earthwork will stand at an inclination of $1\frac{1}{2}$ horizontal to 1 vertical. When, however, it is necessary to use very wet substances, such as peat-moss or wet clays, or when the embankment is of great height, a flatter slope may be necessary. In many cases, it is advisable to substitute a viaduct (q.v.) for an embankment. All embankments put in as above mentioned subside more or less, the subsidence being much more distinctly perceptible in clay than in gravel. When

clay is thrown by the wagon over a considerable tip, the lower half of the embankment will be seen to consist of round bullets of clay of sufficient hardness to resist being squeezed into one mass by the weight of the embankment, until, in the course of time, from the effects of moisture, they become gradually disintegrated, and a settlement or sinking of the embankment takes place, sometimes to the extent of a twelfth, or even a tenth of the height. The greatest sinking usually occurs during the first wet weather after the formation of the embankment; but it sometimes goes on, though more and more slowly, for years. In the case of railway embankments, this subsidence is seldom of very material importance. If the permanent rails are laid, the labor and expense of restoring them to the level is not great, and the embankment should always be formed sufficiently wide at the top to allow of filling it up to its proper level without adding to the slopes. It is, however, practicable, though rather hazardous, to widen it at the top afterwards by cutting trenches in the slopes.

When the side-slope of the ground on which an embankment is to be formed is very steep, the whole work has a tendency to slip laterally; and to prevent this, trenches or steps are cut in the ground before putting in the embankment. When the material is very wet, it sometimes is impossible to prevent the slopes from bulging out, in which case it is generally sufficient to put in additional stuff until the work stands.

Embankments, when finished, have their side-slopes usually covered with soil and sown with grass-seed; this not only improves their appearance, but adds considerably to their stability, preventing rain and wind from doing the damage that might otherwise take place.

In regard to embankments to restrain or prevent the encroachment of water, it is necessary, in addition to forming them of sufficient height and strength, to cover the surface of the slopes in such a way that the action of the water will not affect it. Of course the method adopted must depend entirely on the nature of the case; where, for example, the water only occasionally touches the embankment, as in the case of river-floods, and does not run with great violence along it, good turf pinned to the slopes has been found effectual. Where, however, the slopes are subject to the action of waves or rapid water, more effectual and expensive measures must be adopted, such as stone-pitching, piling, etc. Embankments of this nature are used on a great scale in Holland. See DYKE.

Embankments for damming up water so as to form ponds or reservoirs, require, in addition to the other conditions, to be perfectly water-tight; and for this purpose a "puddle-wall" of clay is carried from top to bottom in the heart of the structure. The great difficulty lies in preventing the water from finding its way between the bottom of the puddle-wall and the foundation on which it rests, or even through the substances of which that foundation consists; and the wall must often be carried to a great depth below the surface of the ground until an impermeable stratum be found. A knowledge of the geology of the place is here essential to the engineer.

EMBARGO (from the Spanish *embargar*, to in-bar, to arrest), is a public order directing the detention in port of vessels, whether foreign or national. It may be for the purpose of using them for some naval operation, or in the event of some projected expedition to insure secrecy, or with a view to temporary non-intercourse with some foreign nation, or by way of reprisals. A hostile embargo by one nation prohibits the departure from its ports of vessels belonging to another with which it is at variance, for the purpose of securing a favorable settlement of the dispute, and in case of war of having an opportunity to make reprisals. While such a prohibition is held to be an established usage, the practice is generally disapproved. A civil embargo aims at non-intercourse, and is laid pursuant to plans of public policy, or for the protection of the merchant vessels of a neutral nation against the rules of belligerents. Of this sort was the famous embargo enacted in 1807, on the recommendation of President Jefferson, as a retaliatory measure to the Berlin and Milan decrees of Napoleon and the English orders in council. It ordered all vessels in the ports of the United States to be detained except those sailing under a public commission, or such as were already laden or should sail in ballast. American coasting vessels were required to give heavy bonds that their cargoes should be landed in the United States. This act was repealed in 1809, after causing the greatest distress among our own citizens. Other embargo acts were that of 1812, which was suspended upon declaration of war with England, and that of 1813, which was repealed after it had been in force for four months.

EMBASSY. In a popular sense, all diplomatic missions are spoken of as embassies; but such is not the technical meaning of the term. In its more limited acceptation, embassy is a mission presided over by an ambassador, as distinguished from a mission or legation intrusted to an envoy, or other inferior diplomatic minister. The United States sends no ambassador to any country, but the highest American diplomatic grade is that of minister plenipotentiary. The only difference between the powers and privileges of the ambassador and the envoy is, that the former represents the person of his sovereign, and in this capacity he can demand a private audience of the sovereign to whom he is accredited; whilst the latter must address himself to the minister for foreign affairs. A residence is provided for the ambassador, and an allowance for house-rent is made to inferior ministers, in addition to their salaries. See AMBASSADOR, ENVOY, CONSUL.

EMBATERION, a war-song of the Spartans, accompanied by flutes, which they sung marching in time, and rushing on the enemy. The origin of the E. is lost in antiquity.

EMBATTLED, or **IMBATTLED**, called also *crenellé*, one of the partition lines in heraldry, traced in the form of the battlements of a castle or tower. A bordure embattled is often given as a difference to any member of a family who is, or has been, a soldier.

EMBATTLEMENT. See **BATTLEMENT**.

EMBER or **EMBERING DAYS**. According to the *Book of Common Prayer* of the Church of England, three days are appointed four times in the year to be observed as days of fasting and abstinence; these days are the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the feast of Pentecost, after the 14th Sept., and after the 13th Dec. The term "embering" has been variously derived from the Greek *ημεραι*, and from the embers or ashes which in the earliest times were strewed over the head at times of fasting, in token of humility and self-condemnation. But the more correct derivation would appear to be from the Saxon *Ymbrine dagas*, from the Saxon *ymb*, about, and *ryne*, a course or running, the term applied to these fasts because they came round at certain set seasons in the year.—Somner, *Dictionarium Saxonici*. This phrase is used in the laws of Alfred the great, and also of Canute, and corresponds with the term used by the canonists, *jejunia quatuor temporum*, the fasts of the four seasons. Mr. Somner says that the embering days were "times of old chosen and set apart for fasting and prayer for obeyning the fruits of the earth, and to give thanks for the same, whereas at those times they are either sowen, sprung up, coming in their ripenesse, or gathered into the barne, as also to obtaine the grace of the Holy Ghost, when holy orders are given and ministers made." It is to this latter purpose that the Church of England in the present day particularly devotes the ember days, and a special prayer is appointed for use at those seasons.

EMBERIZA and **EMBERIZIDÆ**. See **BUNTING**.

EMBEZZLEMENT. The fraudulent appropriation of personal property held in some fiduciary capacity, as that of agent, clerk, or servant. It is a statutory offense. The crime of larceny, which was the common law wrong most nearly resembling it, is feloniously *taking* and carrying away the personal property of another. Larceny cannot be committed without a trespass, by which is meant, in this connection, an *unlawful taking*. It requires that the property stolen should have been, either actually or constructively, in the possession of the owner. When, therefore, a servant, clerk, or other fiduciary, wrongfully took for his own use articles belonging to his employer which had never come into the employer's actual or constructive possession, the common law did not recognize the act as a crime, but only as a breach of trust, for which a civil action could be brought. Thus, if a clerk employed to collect money placed it in his employer's drawer and subsequently abstracted it with intent to steal, the act was larceny, since the property had come constructively into the possession of the owner. But if, instead of depositing it in owner's drawer, he immediately upon receiving it wrongfully applied it to his own use, he could not be criminally punished for the act. Such infractions of right as these are recognized as wrongs by the civil law, and an action for reparation is provided. The defect in the common law led to the enactment of a statute in the year 1799 (39 Geo. III., ch. 85), declaring such an act in breach of trust to be a felony, and naming the offense embezzlement. This statute has been repealed; but it was substantially re-enacted by the act 8, Geo. IV., ch. 29, and subsequently by 24 and 25 Vict., ch. 96, § 68, which is the law now in force.

The American statutes upon this subject are based chiefly upon that of 8 Geo. IV. In addition to the provision that the article taken should not have been in the possession of the employer, that act required, in order to sustain a charge of embezzlement: 1. That the accused should be a clerk or servant, or a person acting in such a capacity. 2. That the property should have come into his possession "by virtue of his employment." 3. That he fraudulently converted, or appropriated, or secreted it for his own use, without the consent or concurrence of his employer, and with intent to steal it or to convert it to his own use. Although that act confined the crime to servants, clerks and persons employed in such capacity, yet the laws are now broad enough in scope, both in England and in many of the United States, to include wrongs of this nature committed by such persons as agents, attorneys, factors, brokers, public officers, trustees of charities, directors and officers of corporations, etc. If, however, the relation of debtor and creditor simply exist between the owner of the articles appropriated and the person who appropriates them, so that he who receives them may, if he choose, regard them as his own, and thus make himself liable to respond to his employer for their value, the act will not be an embezzlement. For example, if a person employed to procure applications for insurance, receives various sums as premiums, and wrongfully applies them to his own use, he is not indictable for embezzlement. If the property come into the possession of the wrongdoer in any other manner than "by virtue of his employment," his retention of it cannot constitute embezzlement. The essential element, in this respect, is that *some confidence shall be violated*. Thus, if a servant, believing himself authorized to receive money for his master, but not being in fact so authorized, receive it and convert it to his own use, he does not commit the

offense. But if he were in fact authorized by his master, it would be no defense for him that the latter was not entitled to receive the money. By the statutes of some American states, it is not necessary, in order to constitute this crime, that the property belong to the employer, so long as it does not belong to the servant or clerk, and is acquired by the wrongdoer by virtue of his employment. But in England it is requisite that the property belong to the employer.

If a person commit the *act* of embezzlement, the presumption is that he meant to embezzle. Still there must be a criminal intent; and if it be proved that the accused honestly believed himself entitled to the property entrusted to him, however much mistaken he may have been, he cannot be convicted of the crime.

In England, one indicted for larceny may now be convicted of embezzlement, if that crime only be proved, and *vice versa*. In some American states, as New York, larceny has been made broad enough to include embezzlement. The punishment prescribed for embezzlement is usually imprisonment for a term of years. Thus, in England, it is imprisonment at hard labor for not less than three nor more than fourteen years.

EMBLA, in Norse mythology, the first woman created. When the gods Odin, Hœnir, and Lodur left their home to wander on the earth, they found Ask and Embla (ash and elm) without power and without destiny; spirits they had not, nor sense, nor blood, nor power of motion, nor fair color. Odin gave them spirit, Hœnir sense, and Lodur blood and fair color. Some have it the gods were Odin, Veli, and Ve. The man they called Ask and the woman Embla. From this pair the human race descended; a dwelling was assigned to them in Midgard (the earth).

EMBLEM, a representation of an object intended to signify or indicate to the understanding something else than that which it directly represents to the eye. The meaning of the *E.* rests upon its secondary, not its primary signification. *E.* is often used in a sense synonymous with symbol, under which, as the wider word, it will be more convenient to treat it.

EMBLEMATA (Gr.), the works of art with which gold and silver vessels were decorated by the ancients. These sculptured figures were generally executed either in the precious metals or in amber. They were called *crustæ* by the Romans, though the Greek word was also used.

EMBLEMENTS (Fr. *emblaver*, to sow with *blé* or wheat), growing crops of cereal and vegetable productions raised by the labor of the cultivator. Fruits of trees growing on the land, and grass, are not emblements. The law has ever been mindful of the interests of the tenant who has expended his toil and capital in tilling the ground. By the feudal law, when a tenant for life died between Mar. and Aug., his heirs were entitled to the profits for the whole year. By the existing law of England, a tenant for life, or other tenant, whose term may be suddenly and unexpectedly brought to a close, is entitled to reap the crop which he has sown, and to enter the lands after expiry of the term to remove the emblements. By 14 and 15 Vict. c. 25, a tenant at rack-rent (q.v.) under tenant for life is entitled, where the tenancy determines by death of tenant for life, to hold the land till the expiry of the current year. But if a term be brought to an end by the act of the tenant, he is not entitled to emblements. Thus, a tenant for life, who commits forfeiture, or a widow entitled to dower—who, as regards dower-lands, is considered tenant for life—marrying again, are not entitled to emblements. On the death of a tenant, the executor, and not the heir, is entitled to the emblements. By 11 Geo. II., c. 19, *E.* may be distrained for rent, and by common law they may be taken in execution. The right of life-renters in Scotland to reap the growing crop is somewhat similar to the English right to emblements. See **LIFE-RENT**.

EMBLICA, a genus of plants of the natural order *euphorbiaceæ*, having a fleshy fruit. *E. officinalis* is a tree found in most parts of India, with a crooked stem, thinly scattered spreading branches, long narrow leaves, minute greenish flowers, and a globular fruit about the size of a gall-nut. The fruit is very acid, and somewhat astringent, which qualities it retains when dry and shriveled. It is used in India as a deobstruent and febrifuge, also for tanning leather, and making ink, and is generally called *emblic myrobalans*.

EMBOLISM (derived from the Greek word *embolon*, a plug) is the term employed by recent pathologists to designate the plugging-up of a vessel by a clot of coagulated blood-fibrin, by a detached shred of a morbid growth from a diseased cardiac valve, etc. It is in cases of ill-nourished, broken-down constitutions, or after a protracted or a debilitating illness, that the morbid tendency of the fibrin to coagulate spontaneously within the veins chiefly exists, and in such cases very trivial circumstances may call it forth, especially if they lead to any pressure on the vessel. Clots, or portions of a clot, may be transported by the blood-current from the venous system to the right side of the heart, and block up the pulmonary artery either entirely or in part; if the occlusion is entire, sudden death is produced; while, if it is only partial, gangrene, or inflammation of a part of the lung, commonly ensues. Many of the sudden deaths of women in child-bed (till recently quite inexplicable) are due to this cause, the plug being formed in the inflamed uterine veins, or possibly, in some cases, in the right side of the heart, and passing from thence to the spot where its arrest proves suddenly fatal. Several cases

of this kind are reported in Simpson's *Obstetric Memoirs*. Similar accidents may happen in the arterial system. A detached fragment of a diseased tricuspid or aortic valve of the heart, or a separated fragment of coagulated fibrin, may be driven onwards in the blood-current, and enter and occlude some of the cerebral arteries, causing softness of the brain, by cutting off the due supply of nourishment. For further details, the reader is referred to an exhaustive treatise on this subject published a few years ago by Cohn, entitled *Ueber embolischen Krankheiten*.

EMBOSSING, the art of producing raised figures upon various substances, such as paper, leather, wood, metals, etc. This is usually effected by pressing the substance into a die, the kind of die and mode of applying the pressure being modified according to the nature of the design and the properties of the substance to be embossed. Sheet-metal is embossed by stamping it between a pair of steel dies, one in relief, the other in intaglio. See **DIE-SINKING**. When the pattern is a deep one, several pair of dies are used, and several blows given with each, the metal being occasionally annealed. The first stamping produces a crude resemblance to the final design, of moderate depth; successive stampings bringing up more of the details, and giving increased depth. The upper die is usually raised by a rope attached over a pulley to a stirrup, in which the workman places his foot; he draws his foot down to raise the heavy die to the required height, and then suddenly releases the pressure of his foot from the stirrup, when the die descends by its own weight. While thus raising the die with his foot, he adjusts the work in its place with his hands. Smaller work is embossed with a screw-press, the lever of which is turned with one hand, while the work is placed under the dies and removed by the other. Paper and card are embossed in a similar manner, but the dies are frequently of brass, sometimes of copper electro-deposits, suitably backed. The counter-die is commonly made of soft metal, card or mill board, pressed into the metal intaglio die until a sharp impression is produced. The paper or card is well damped, and a fly-press is generally used. The leather or cloth for bookbinding is embossed in this manner, the counter-die being usually made by gluing several pieces of mill board together, and gluing them to the upper bed of the press, then stamping these into the lower die until a perfect impression is obtained. The embossing press designed and constructed by Mr. Edwin Hill, for impressing the medalion upon postage envelopes, is a very elaborate and beautiful machine, which inks the die itself, and with the aid of two boys, to place and remove the envelopes, embosses sixty envelopes in a minute. When large surfaces of textile fabrics, such as table-covers, etc., have to be embossed, the fabric is compressed between rollers, one being of metal, upon which the device is sunk like a die; the counter-roller or bed-cylinder is of paper covered with felt; this yields sufficiently to allow the fabric to be pressed into the die-cylinder. A third smooth metal roller is commonly used to press out again the impression made upon the bed-cylinder; this acts upon the bed-cylinder on the side from which the fabric emerges. Paper is sometimes embossed in this manner; and the flattening roller may be dispensed with if the cylinders are sufficiently accurate in their diameters for the pattern always to fall on the same place at each successive revolution. Leather embossed in high relief has been used for ornamental purposes in place of wood-carving, on picture-frames, cabinet-work, etc. The dies are of type-metal or electro-deposits, and the leather is softened or felled, i.e., worked with water till it contracts and thickens, then it is pressed into the dies by suitable round pointed tools, like modeling tools, made of wood, bone, or copper. When dry, the leather is removed from the molds, and by its elasticity and shrinking it will relieve from very deep and undercut designs.—Mr. Straker's mode of embossing wood differs from all the above, and is very curious and ingenious. When wood is pressed and rubbed with a blunt instrument, the surface yields, and a depression of some depth may be made in it; if the wood be now soaked in water, the depressed portion will rise again to its original level. Mr. Straker takes advantage of this property thus. He rubs down the surface in those parts that are to be finally in relief, he then planes or shaves away the uncompressed portions until the bottom of the depressions are reached and made level with the new surface; the wood is then soaked; the compressed parts rise to their original level, and, of course, in doing so, rise above the portions that have been planed away, and present the required device in relief.

EMBOUCHURE (Fr.), that part of a wind instrument to which the lips are applied to produce the sound, also the manner in which the lips are applied.—The term **EMBOUCHURE** is also applied to the mouth of a river.

EMBOWED, the heraldic term for anything which is bent like a bow. A sinister arm couped at the shoulder, is embowed. When the arm is turned the reverse way, it is said to be counter-embowed.

EMBRA'CERY is, in American law, the offense of influencing jurors by corrupt means to deliver a partial verdict. This offense is a species of maintenance (q.v.). The giving of money to be distributed amongst jurors is embracery, though the money be not actually distributed. Not only persons attempting to influence the jury, but jurors themselves attempting unduly to bias the minds of their fellows, are guilty of embracery. The using indirect means in order to be sworn on a jury, is also embracery. This offense

is punishable by various old statutes. The recognition of the crime of E. is universal in the U. S. The punishment differs in degree according to the various state statutes, but the fact is everywhere recognized that the offense is one which should meet with severe punishment. It is obvious that upon the honesty of the jury depends the just maintenance of law and the due administration of justice. It is not necessary that money be given to constitute E.; improperly influencing is sufficient. This applies to attempts improperly to influence referees as well as jurors.

EMBRA SURES, in fortification, are openings in the parapets, flanks of bastions, and other parts of the defense-works, through which cannon are pointed. The siege-batteries of the enemy have also embrasures. Their use is, to shield as much as possible the guns, gun-carriages, gunners, and interior of the place, and yet leave spaces for the free firing of the guns. Each opening slopes upwards, so as to give a greater sweep to the gun's action. See *illus.*, **FORTIFICATION**, vol. VI.

EMBROCA'TION (Gr. *em*, into, and *brechō*, I wet), the same as liniment (q. v.).

EMBROIDERY, the art of producing ornamental needlework-patterns upon fabrics of any kind. This art is coeval with the earliest and rudest manufacture of hair and woolen fabrics. It was one of the most important of the early arts in oriental countries, where it is still practiced with great skill and diligence. It is common among most savage tribes that wear any kind of clothing. The blanket-wrapper of the red Indian is commonly ornamented with E.; the Laplander embroiders upon the reindeer skin that forms his clothes patterns worked with needles of reindeer bone, and thread of reindeer sinews and strips of hide. It is practiced as a domestic art in our own country by all classes, from the princess down to the pauper school-girl, and is carried on in large manufactories by very elaborate machinery.

The Chinese are perhaps the most laborious and elaborate hand-embroiderers of modern times; their best work is upon silk. The figures are either in colored silk alone, or in silk combined with gold and silver thread; the figures of men, horses, dragons, etc., being outlined with gold cord, and filled up colored and shaded with silk. The Persians, Turks, and Hindus also still excel in E.; they use, besides silk and gold and silver thread, beads, spangles, pearls, and precious stones. The dress-slippers of Turkish women of all ranks are elaborately embroidered, usually with a precious stone or a glass bead in the middle of the toe-part of the slipper, and a radiating pattern in gold, silver, or brass wire and silk surrounding it. The Turkey carpet is a sort of embroidered fabric. See **CARPETS**.

Some of the oriental and Indian embroideries include in their work a great variety of materials besides those above mentioned; feathers are largely and very tastefully used; the skins of insects; the nails, claws, and teeth of various animals; nuts, pieces of fur, skins of serpents, etc., are among these. Coins, which are so commonly used as ornaments for the hair of unmarried women in the east, are sometimes also worked into their dresses with the embroidery. This is especially the case with the Turks and Georgians. The Indian women embroider with their own hair and that of animals.

Tapestry is a kind of E., formerly done with the needle, but now chiefly with the shuttle. This kind of work is, in fact, intermediate between E. and weaving, and it is somewhat difficult to determine under which it should be classed, but in accordance with the definition given above, we shall only include needlework under E., and tapestry will be separately treated.

For hand-embroidery, the fabric is usually stretched upon a frame, and the design to be worked is drawn upon it, or some other contrivance is used to guide the worker. If the fabric is sufficiently thin and open, a colored drawing or engraving may be placed behind the work, and followed with the needle. A sheet of thin transparent paper, with lines upon it corresponding to the threads of the canvas to be worked upon, is sometimes used; this is secured by gum or wax to the drawing; and the design is copied by observing the number of small squares occupied by each color, and filling in the corresponding meshes of the canvas. *Berlin-work*, which is a kind of E., is done in a similar manner, the pattern being an engraving on which the lines corresponding to the thread are printed, and the meshes filled up with the required colors, painted in by hand, by women and children, who copy it from the original design of the artist. The name has been given from the fact, that the best patterns have, since 1810, been published by Wittich, a printseller of Berlin.

In France, pricked patterns are sometimes used, one for each color, and colored powders are dusted through the holes upon the fabric to be worked.

All these devices render the art of E. a mere mechanical operation, requiring no further artistic skill or taste than is exercised in knitting stockings; but when the embroidress draws the design in outline upon the fabric, and works in the colors with her needle under the guidance of her own taste, E. becomes an art that might rank with water-color drawing or oil-painting; and it is to be regretted that so much time should be devoted by ladies to the mechanical, and so little effort made in the direction of truly artistic embroidery.

Machine-embroidery has been practiced with considerable success during the last quarter century. A machine was exhibited in the French industrial exhibition of 1854, by M. Heilmann of Mulhausen, by which one person could guide from 80 to 140 needles.

all working at the same time, and producing so many repetitions of the same design. Although the details of the construction of this machine are rather complex, the principle of its action may be easily understood. The needles have their eyes in the middle, and are pointed at each end, so that they may pass through from one side of the work to the other without being turned. Each needle is worked by two pair of artificial fingers or pincers, one on each side of the work; they grasp and push the needle through from one side to the other. A carriage or frame connected with each series of fingers does the work of the arm, by carrying the fingers to a distance corresponding to the whole length of the thread, as soon as the needle has passed completely through the work. The frame then returns to exactly its original place, and the needles are again passed through to the opposite set of fingers, which act in like manner. If the work were to remain stationary, the needles would thus pass merely backwards and forwards through the same hole, and make no stitch; but by moving the work as this action proceeds, stitches will be made, their length and direction varying with the velocity and the direction in which the work moves. If 140 needles were working, and the fabric were moved in a straight line, 140 rows of stitching would be made; if the work made a circular movement, 140 circles would be embroidered; and so on. In order, then, to produce repetitions of any given design, it is only necessary to move the fabric in directions corresponding to the lines of the design. This is done by connecting the frame on which the work is fixed to an apparatus similar to a common pantagraph, or instrument so constructed that one end repeats on a smaller scale exactly the movements which are given to the other. See PANTAGRAPH. The free end of this is moved over an enlarged copy of the design, the movement being a succession of steps, made after each set of needles has passed through; and thus the work is moved into the position required to receive the next stitch of the pattern.

This machine was subsequently patented in England, and many improvements have been made upon its details, but the principle of its construction remains the same.

Although it is possible to embroider any design with such machines, there are only certain designs that can be worked economically; for to do this, the patterns must be so designed as to consume each needleful of silk without waste. The length of silk required for each color can be calculated with extreme accuracy, and the designer is usually limited by this requirement. A greater range is, however, obtainable by dyeing the same thread of silk in different colors, the length of each color corresponding to what is required for producing the pattern; but a large demand for each pattern is required to render this profitable.

EMBRUN, a t. of France, in the department of Hautes Alpes, is situated on a platform of rock in the midst of a plain, on the right bank of the Durance, 20 m. e. of Gap. Seen from a distance, the town has an imposing appearance. The streets of E. are narrow, dirty, and irregular. It is surrounded by loop-holed ramparts and ditches, and strengthened by bastions. The principal buildings are the cathedral, a Gothic edifice, surmounted by a lofty Romanesque tower, and the barrack, formerly the archbishop's palace. E. manufactures broadcloth, counterpanes, hats, cotton-yarn, and leather. Pop. of commune, '91, 4017.

E. occupies the site of the ancient Ebrodunum, capital of the Caturiges, and an important Roman station. The line of its archbishops can, it is said, be traced to the time of Constantine. In modern times E. has been thrice destroyed by fire: by the Moors in 966, during the religious wars in 1573, and by the duke of Savoy in 1692.

EMBRYO (Gr.), an organized being in a rudimentary condition, or the rudiment from which, under favorable circumstances, an organized body is to be developed. In botany, the term E. is applied to the germ formed within the ovule on fertilization, and which increases to become the principal part of the seed. The albumen or perisperm of the seed, being regarded as a mere store of nourishment for the E., is not accounted part of the E.; the cotyledons, however—although a large store of nourishment is often laid up in them—are considered as essentially belonging to it, along with the *plumule*, the *radicle*, and the connecting parts. As to animals, the term E. is used as equivalent with *fœtus*, and as designating the rudimentary animal from the moment of impregnation until the egg is hatched; but although this takes place at very different stages of development in different kinds of animals, and consequent metamorphoses are undergone by some before they reach their perfect state, the term E. is not applied to the *larvæ* and *pupæ* of insects, or to the analogous states of other classes of animals. Eggs contain, along with the E., a store of nourishment for it in the earlier stages of its development. See REPRODUCTION, DEVELOPMENT OF THE EMBRYO, EGG, FŒTUS, OVULE, SEED, and SPORE.

EMBRYOLOGY. See DEVELOPMENT OF THE EMBRYO.

EMBRYOTOMY, a division of the fœtus into fragments, to extract it by piecemeal, when the narrowness of the pelvis or other faulty conformation opposes delivery.

EMBURY, EMMA CATHERINE, 1806-63; b. New York; daughter of Dr. James R. Manley. She published many poems and prose sketches and tales, among them *Guido and Other Poems*; *Constance Latimer, or the Blind Girl, and other Tales*; *Pictures of Early Life*; *Glimpses of Home Life*; *Nature's Gems, or American Wild Flowers*; *Love's Token Flowers*; *The Waldorf Family*, etc.

EMBURY, PHILIP, b. Ireland, 1729; d. Troy, N. Y., 1775; widely known as the "founder of American Methodism." He was of German descent, and came to America in 1760. In 1766 he organized a society in New York, and the next year began to preach in a rigging loft, which place became famous as the cradle of Methodism in this country. The next year a church was built, on the site of the present old John street church, partly by E.'s own hands. About a year later a company of missionaries sent out by Wesley arrived in New York, and Embury went as a missionary to the region around Albany and Troy. He died suddenly from an accident.

EMDEN, a t. in the province of Hanover, once in the principality of East Friesland, is situated a little below the embouchure of the Ems into Dollart bay, in lat. 53° 22' n., long. 7° 13' east, 40 miles west by south from Wilhelmshaven, and 14 miles southwest of Aurich, with which it is joined by a canal. It lies low, but is protected by strong dykes from any inroad of the waters of the bay. Nevertheless, occasional inundations have taken place; as in 1826, when the water stood up to the first floor of the houses for three months. E., which is the chief commercial town of Hanover, is surrounded by walls and towers, is well built, has spacious and well paved streets, and houses remarkable for their appearance of comfort, and for their extreme cleanliness. It is intersected by numerous canals, which are crossed by many bridges. Communication with the port from the river Ems is afforded by the Nesserland locks, which formerly admitted vessels of 17 ft. draft, but since 1893 great improvements have been made. There is telegraphic communication by cable between Emden and the town of Valentia, Ireland. The principal building, and one of the finest public edifices in the whole region, is the town hall, containing a library and a curious collection of ancient arms and armor. E. stands in a district of great fertility. It has a good deal of shipbuilding, besides various other manufactures. Many of its vessels are engaged in the herring-fishing off Scotland. E. was made a free port in 1751, came into the possession of Holland in 1808, and with the whole of East Friesland, was incorporated with the kingdom of Hanover in 1815. Pop. '90, 13,424.

EMERALD (Sp. *esmeralda*, Fr. *émeraude*, Ger. *smaragd*, Gr. *smaragdos*; the name is originally Semitic, or at least eastern, but the signification unknown), a mineral generally regarded by mineralogists as merely another variety of the same species with the beryl (q.v.), with which it essentially agrees in composition, crystallization, etc., differing in almost nothing but color. The E., which, as a gem, is very highly valued, owes its value chiefly to its extremely beautiful velvety green color. It is composed of about 67 to 68 per cent. of silica, 15 to 18 of alumina, 12 to 14 of glucina, and a very little peroxide of iron, lime, and oxide of chromium. Its color is ascribed chiefly to the oxide of chromium which it contains. Its specific gravity is 2.577 to 2.725. In hardness it is rather inferior to topaz. The localities in which E. is found are very few. The finest have long been brought from South America, where they are obtained from veins traversing clay-slate, hornblende slate, and granite, in a valley not far from Santa Fé de Bogota, Colombia, at a place called Muzo. One stone found at Muzo in 1884 weighed in the rough more than a pound, and is believed to be the largest ever discovered. In several localities in Alexander county, N. Carolina, emerald varieties of beryl are frequently found. Emeralds of inferior quality are found in Europe, imbedded in mica-slate in the Henbach Valley in Salzburg. They are also found in the Ural; and some old mines in Upper Egypt have also been discovered to yield them, from which, probably, the ancients obtained them. This gem, known from very early times, was highly prized by the ancients. Pliny states that when Lucullus landed at Alexandria, Ptolemy offered him an E. set in gold, with his portrait engraven on it. Many wrought emeralds have been found in the ruins of Thebes. Nero, who was near-sighted, looked at the combats of gladiators through an eye-glass of E., and concave eye-glasses of E. seem to have been particularly esteemed among the ancients. As a precious stone, the E. is rarely without flaw. Its value also depends much on its color. A very perfect E. of six carats has been sold for \$5000.

It appears not improbable that emeralds have been found in the east, in localities not at present known, but the name E. or ORIENTAL E. is often given to a very rare, beautiful, and precious green variety of sapphire (q.v.).

E. COPPER is a beautiful and very rare E. green crystallized mineral, also called DIOP-TASE, found only in the Kirghis Steppe, and composed of about 39 parts silica, 50 prot-oxide of copper, and 11 water.

EMERALD BIRD OF PARADISE, a native of New Guinea, and one of the most beautiful of its order. The skins and feathers are highly prized for ornament, and bring large prices.

EMERALD ISLE, a popular name for Ireland (q.v.).

EMERALD WEDDING. See WEDDING ANNIVERSARIES.

EMERITUS (Latin *emeriti*, to serve out, to complete one's term of service), a term originally applied to a Roman soldier who had *served out* his time, and had been honorably discharged, receiving an allowance corresponding somewhat to the modern half-pay, given to soldiers who retire after honorable service. The term *emeritus* is now employed to designate certain functionaries, such as professors and rectors, who have been honorably relieved from active labors by reason of age, infirmity, or long and faithful service.

EMERODS (Gk. *hæmorrhoids*, a pile). This is a corruption of the word hemorrhoids, and in the Bible text (see I. Sam. v. 12) refers to a disease similar to the modern disease called piles (q.v.).

EMER'SION, the reappearance of one heavenly body from behind another, after an eclipse or occultation. The immersions and emersions of Jupiter's first satellite are particularly useful for finding the longitude of places. Minutes or scruples of emersion are the arc of the moon's orbit passed over by her centre, from the time she begins to emerge from the earth's shadow to the end of the eclipse.

EMERSON, GEORGE BARRELL, LL.D., b. Maine, 1797; graduate of Harvard, where he was afterwards tutor in mathematics and natural philosophy. He was a popular teacher in Boston until his retirement from professional life in 1855. He published a second part to *School and Schoolmaster*; *A Manual of Architecture*; *Report on the Trees and Shrubs growing naturally in the forests of Massachusetts*, etc. He served as president of the Boston society of natural history, and as chairman for the commission for the zoological and botanical survey of the state. He d. in 1881.

EMERSON, RALPH WALDO, LL. D., an eminent American poet and essayist, was born in Boston, May 25, 1803. He was of clerical lineage, being the eighth in succession of a consecutive line of Puritan ministers. His father, who died when he was but seven years of age, was the Rev. William Emerson of the First church in Boston. He was fitted for college in the Boston public Latin school, entered Harvard in 1817, and graduated in 1821. His tastes were literary rather than scholastic. In the Latin school he wrote verses for exhibition days, and in college the library had for him more charms than the text-books. His rank as a student was not above that of some others in his class, though he took two prizes for dissertations and one for declamation, and was the class-day poet at the time of his graduation. For five years after leaving college he was engaged with his brother William in teaching a successful school for girls in Boston. During this time he must have given attention to theological studies, for he was "appropriated to preach" in 1826. After this, for the benefit of his health, he passed a winter in South Carolina and Florida. In Mar., 1829 he was ordained as colleague of the Rev. Henry Ware in the Second Unitarian church in Boston. His pastorate was short, for he soon found himself entertaining scruples concerning the ordinances of the church, and especially unwilling to administer that of the Lord's Supper. His resignation of his pulpit and of the ministry for such a reason made no little stir in the Unitarian denomination, and in the other Christian sects, being regarded as a very strange event. The parting between him and his congregation, in 1832, was most honorable and affectionate on both sides, for, as a preacher, he had won popularity and favor. He now went to Europe for a year, and on his return, in the winter of 1833-34, he began in Boston his eminent career as a lecturer, with a discourse upon "Water," before the Boston manufacturers' institute. Three other lectures, two upon "Italy," and one on "The Relation of Man to the Globe," were delivered during the same season. Shortly after this he delivered in Boston a course of biographical lectures on Michael Angelo, Milton, Luther, George Fox, and Edmund Burke; the first two of which appeared afterwards in the *North American Review*. After that day, and as long as he lived, Mr. Emerson was among the most conspicuous and popular of American lecturers, traveling extensively in the eastern, northern, and western states, and attracting large audiences, less by any oratorical gifts than by the solid value of his thoughts. In some places he remained a great favorite, speaking by invitation for the fortieth or fiftieth time in the same lyceum course, with undiminished interest. In 1835, Emerson took up his residence in Concord, Mass., where he was esteemed the foremost citizen in the place, sharing the love, honor, and reverence of all the people, without distinction of party or sect. In 1835, and the three or four following years, he delivered in Boston successive courses of lectures on English literature, the philosophy of history, human culture, human life, and the times. In 1834, he delivered a poem before the Phi Beta Kappa society of Harvard; in 1837, an oration before the same society upon "The American Scholar;" and in 1838, an address to the senior class of the Cambridge divinity school, which created no little stir in the literary and theological world. His first book, a thin volume entitled *Nature*, appeared in 1836, and was received by a few enthusiastic admirers as opening a new era in American thought, while in some quarters it was sharply criticised. In 1841, appeared *The Method of Nature*, which developed more fully the peculiar qualities of his mind and his ways of thinking, and by its freshness and beauty won him many admirers. For reasons which to many leaders of popular thought were incomprehensible, he was rapidly gaining a strong hold upon the affection and reverence of an increasing multitude of his countrymen, and winning the attention of thoughtful men on the other side of the Atlantic. The "transcendental" movement, so called, was coincident with the appearance of his earliest works, and received from them both impulse and direction. In 1840, appeared a quarterly magazine entitled *The Dial*, with Miss Margaret Fuller as editor, assisted by A. Bronson Alcott, William E. Channing, Emerson, Theodore Parker, George Ripley, and others. This periodical was continued four years, during the last two of which Emerson was the editor. Two volumes of *Essays* were Emerson's next issues, the first appearing in 1841, the second in 1844. His collected *Poems* were published in 1846. In 1847, he visited England to fulfill engagements as a

lecturer, and was warmly received by the lovers of his books, and by the public generally. In 1849, he collected into a volume of *Miscellanies* his "Nature," and nine lectures and college addresses, which had previously appeared in *The Dial*, or in pamphlet form. In 1850, appeared his *Essays on Representative Men*, a work of great interest and power. In 1852, he assisted in preparing the memoirs of Margaret Fuller Ossoli. In 1856, he published *English Traits*, a work which well illustrated his powers of accurate observation, and his clear understanding of the workings of human nature under various conditions. Next appeared, in 1860, *The Conduct of Life*, a work which brings clearly to view the exalted moral and ethical principles which underlie and pervade all that he has written. A subsequent volume embraced a portion of his contributions to the *Atlantic Monthly*. In 1867, appeared a volume of his poems, *May Day and Other Pieces*. In 1870, he published *Society and Solitude*, and in 1869, appeared his *Prose Works Complete*. In 1875, he published four series of *Essays*. In 1878, in the *North American Review*, appeared a paper, *Sovereignty of Ethics*, which fixed the public attention as the ripest fruit of his broad culture; and in 1880, the *Unitarian Review* published, under the title of "The Preacher," his address of 1879 in the divinity chapel at Cambridge. In 1878, he spoke on "The Fortune of the Republic," in the Old South Church; and, 1880 (for the hundredth time), in Concord, on "New England Life and Letters." In the midst of his literary labors Emerson always had time to manifest his interest in great public questions as they arose. Some of his letters upon passing events in the newspaper press have exerted a wide influence. While he was a pastor in Boston he opened his pulpit to an earnest protest against American slavery, and during the whole period of the antislavery agitation he constantly manifested his sympathy with those who sought to deliver the land from the curse of human bondage. In 1844, he gave emphatic expression to his views in an address delivered upon the 1st of Aug., the anniversary of emancipation in the British West Indies. Though not in the technical sense of the word a reformer, his habits and tastes being rather those of a scholar and man of letters, every earnest movement for the welfare of humanity secured his sympathy. He gave his name to the call issued in 1850 for the first convention ever held in Massachusetts to secure for women equal rights with men as citizens and voters. He was member of the American academy of arts and sciences, of the American philosophical society, of the Massachusetts historical society, and a vice-president of the free religious association. He was also a member of the board of overseers of Harvard university, from which he received the degree of doctor of laws in 1866. His writings, though marked by an ethical and spiritual vitality of the highest order, are utterly devoid of system, and pervaded by a certain mystical quality, charming to some but bewildering to others. His intellectual gems are profusely sown throughout his pages according to no visible or conscious method, and with settings that seem quite accidental; but they glow with a genuine luster wherever found. To the arts and processes of the logician he pays no regard, evidently thinking that they tend to belittle, rather than exalt, the truth. He simply affirms what he believes, making his appeal at every step to the moral intuitions of the reader, in the faith that the "spirit of man is the candle of the Lord," with a power of illumination adapted to every emergency. His position is clearly indicated in a simple sentence from his address at the divinity school in 1838: "The assumption that the age of inspiration is past, that the Bible is closed, the fear of degrading the character of Jesus by representing him as a man, indicate with sufficient clearness the falsehood of our theology." His earlier writings are supposed by some to show a drift towards pantheism, but others repel this interpretation as unjust. Certainly he had never called himself a pantheist, and there is unquestionable evidence that whatever may have been his former speculations, that name could never truly be applied to him. His friend A. Bronson Alcott reports him as saying: "I do not care to classify myself with any painstaking accuracy with this sect or with that; but if I am to have any appellation at all of a religious kind, I prefer to be called a Christian theist. You must not leave out the word Christian, for to leave out that is to leave out everything." Confirmation of this is to be found in his latest publication, *The Preacher*, in which he says: "Unlovely, nay, frightful, is the solitude of the soul which is without God in the world. To see men pursuing in faith their varied action, warm-hearted, providing for their children, loving their friends, performing their promises—what are they to this chill, houseless, fatherless, aimless Cain, the man who hears only the sound of his own footsteps in God's resplendent creation?" Emerson died at Concord, April 27, 1882. See Ireland, *Ralph Waldo Emerson, a Biographical Sketch* (Lond., 1882); Conway, *Emerson at Home and Abroad* (1882); Cooke, *Ralph Waldo Emerson; Life, Writings and Philosophy* (Boston, 1882); O. W. Holmes, *Ralph Waldo Emerson* (Boston, 1885); Cabot, *A Memoir of Ralph Waldo Emerson* (Boston and N. Y., 1887), the standard authority; Montégut, *Essais de Philosophie Américaine* (1851); the complete works edited by Cabot (11 vols., Boston), and the English edition with introductory essay by Morley (Lond., 1882).

EMERY (Fr. *éméril*, Ger. *schmergel*, Gr. *smiris*; allied to *smear*), a variety of corundum (q.v.), or of the same mineral species of which corundum and sapphire (with oriental ruby, etc.) are also varieties. It agrees with them very perfectly in composition, hardness, and specific gravity; but is dull, opaque, and not crystallized, sometimes of a grayish black, and sometimes of a blue color. It occurs both massive and disseminated. Its masses, although very compact, have a somewhat granular structure. It is found in several parts of Europe, in Asia Minor, Greenland, etc., generally in masses scattered

through aqueous deposits, but in one locality in Saxony in beds of steatite in a schistose rock. The E. of commerce is chiefly obtained from the island of Naxos. Being very hard, it is much used for grinding glass and polishing metals and other hard substances. It is found in lumps, having a granular structure. It is composed of alumina, oxide of iron, and silica, with a little lime, in proportions varying considerably with different specimens. The following may be taken as an average: alumina, 82; oxide of iron, 10; silica, 6; lime, 1½.

It is prepared for use by first breaking it into lumps about the size of a hen's egg, then crushing these to powder by stampers. It is then sifted to various degrees of fineness, which are numbered according to the meshes of the sieve. Plate-glass manufacturers and others separate E. powder into different degrees of fineness by the method of *elutriation* (q.v.). A number of copper cylinders of graduated capacities are placed in a row, and filled with water; the E., churned up with an abundance of water, is admitted by a pipe into the smallest, it then passes to the next in size, and finally flows from the largest; and thus, as a given quantity of water with E. suspended in it, passes in equal times through vessels of varying capacities, the amount of agitation will obviously be greatest in the smallest vessel, least in the largest, and in like proportion with the intermediate; the largest particles, therefore, sink in the smaller vessel, and so on till only the very finest will reach the largest vessel. In this manner, any number of gradations of fineness may be obtained, according to the number and sizes of the vessels. Elutriation in oil or gum-water is sometimes used on a smaller scale, the E. being stirred up in the liquid, and portions poured off at different intervals of time, the finest being, of course, the last to settle. The use of the oil or gum is to make the subsidence take place more slowly.

E. thus prepared is used for a great many important purposes in the arts. Being next in hardness to diamond-dust and crystalline corundum, the lapidary uses it for cutting and polishing many kinds of stone. Glass-stoppers of all kinds are ground into their fittings with it. Plate-glass is ground flat by its means; it is also used in glass-cutting, and in grinding some kinds of metallic fittings. When employed for the polishing of metals, it has to be spread on some kind of surface to form a sort of fine file. *E. paper*, *E. cloth*, *E. sticks*, *E. cake*, and *E. stone*, are various contrivances for such purposes.

E. paper is made by sifting E. over paper which has been covered with a coating of glue. It is used either by wrapping it round a fine file, or a stick, or in the hand, according to the form of the work. See POLISHING OF METALS.

E. cloth is made like E. paper, with coarse calico substituted for the paper. The E. does not adhere so well as to paper, and it is therefore not used by metal-workers, who work E. paper till smooth with wear, but is chiefly used for purposes where the hand alone is used, and paper would tear.

E. sticks are used for the same purposes as E. paper wrapped round files; they are made of deal sticks shaped like files, then glued over, and dipped once or twice in a heap of emery.

E. stone is a kind of earthenware mixed with E., formed by pressing a mixture of clay and E. into suitable molds, and then firing, like common earthenware. It is molded into wheels, laps, etc. Its hardness and cutting power are very considerable.

EMERY, a co. in Utah; formed 1880. 5723 sq. m.; pop. '90, 4866. Co. seat, Castledale.

EMESA. See HEMS, or HOMS.

EMETICS, medicines given for the purpose of producing vomiting (q.v.). They are given when it is desirable to relieve the stomach of some noxious or indigestible substance, as a narcotic poison, or excess of food, or some special article of diet which has disagreed. E. are also administered in cases of fever, where the copious secretion they produce from the glands of the stomach and intestines is supposed to have a directly curative effect, aided, perhaps, by the sedative action of E. upon the circulation and nervous system. There is a considerable amount of evidence to show, that E. have the power of cutting short typhus and other fevers in the earliest stage, and afterwards of making the attack of the disease less severe. In diseases of the respiratory organs, E. are given as the quickest and safest method of removing accumulated mucus from the air-passages; and in croup (q.v.), their action is especially favorable, being often followed by expectoration and a rapid improvement in the suffocative symptoms. E. are to be given with great caution, however, in all very depressed states of the system, as their primary action is to produce nausea (q.v.), which is attended always with more or less diminution of the vital power, and often with great depression of the heart's action, amounting to syncope or fainting. The principal E. are the preparations of antimony, zinc, and copper; ipecacuanha in powder or in wine; squill, lobelia, and, generally speaking, the whole class of expectorants and irritants; the latter of which, however, with the exception of sulphate of zinc, and perhaps mustard and water, form a dangerous kind of E., which should never be administered when the milder kinds can be procured.

EMETINE is the alkaloid which forms the active principle of ipecacuanha root. It is a yellowish-white powder, which is slightly soluble in cold water, but dissolves readily in alcohol. When taken internally, it exhibits violent emetic properties, ʒ of a grain being sufficient to cause vomiting. See IPECACUANHA.

EMIGRATION AND IMMIGRATION. Emigration is the passing out of any part of the world by one who means to settle permanently elsewhere. Immigration is the passing into the new country where he proposes to make his home. Thus every *emigrant* is at the same time an *immigrant*—an emigrant with respect to his old home; an immigrant with respect to his new.

Emigration is as old as history itself, and has exercised a most important influence upon the history of the human race. A great wave of emigration from the East populated Europe with tribes of the Aryan race. Emigration from Greece, prompted by the constant political struggles there, led to the planting of numerous Greek colonies in southern Italy and Asia Minor, and even as far west as Massilia (Marseilles), in what is now France.

The Romans, too, were great colonizers, but by conquest rather than by emigration. They disliked leaving Italy; and the military and civil officers necessary to rule a colony were generally the only Romans who abode in it. These, even, did not, in general, settle in the colonies with their families, but were recalled after a certain period of service, the whole arrangement much resembling that for the government of British India.

The migrations of the northern tribes who overran the Roman empire are well known in history; their wanderings may be said, indeed, to have continued down to the thirteenth century. Those who wandered from the north into France, where they acquired great territories, became known as Normans, and were remarkable for entirely throwing off the language and manners, and even all the traditions of their original homes, and becoming the most civilized and courtly portion of the French people. But though thus changed, they still continued to wander, spreading over Britain, Sicily, and the intervening portions of Europe.

The discovery of America opened a vast new field for E., which was taken immediate advantage of by the Spanish and Portuguese, and later by the British, the French, the Germans, and the Dutch. In the seventeenth century, many of the English Puritans, persecuted in, or discontented with, their own country, found it more congenial to their tastes to live together in a new country, where they would be free from the presence of those who did not sympathize with them, and they thus founded the New England colonies. It is singular that, in the nineteenth century, an attempt should be made to revive the plan of emigrating for the purpose of maintaining an exclusive church, as, for instance, in the English high-church colony of Canterbury, and the Scotch free-church colony of Otago.

The great fields for emigration to-day are the United States, Canada, Brazil, and the Argentine Republic; Australia, Cape Colony in South Africa; the newly established (1886) German colonies in East Africa; and also the Congo Free State (q.v.).

Emigration from Europe.—Since 1820, the stream of emigration from Europe to other parts of the world has been steadily increasing in volume. The hard conditions of life there, the keen competition in every sphere of industry, the over-population, and the crushing burdens imposed by the enormous military establishments, have proved the greatest stimulus to emigration. Great Britain for years led all other countries in the numbers that she has sent forth. In 1815 there left her shores 2081; in 1817, 20,634; in 1819, 34,787; in 1832, 103,140, this being a year of great financial depression. From 1832-45, the annual average was 75,000; in 1852 the number rose to 368,764. In 1890 it was 122,085. German emigration is next in importance to British, and grew steadily up to 1854. In 1830 it was about 22,000; in 1847, 110,434; in 1854, 251,931. It has never since reached so large a figure. In 1889 it was 96,032, and of late years has averaged about 100,000 per annum. Italy in the last decade has taken the second place in point of numbers. In 1876 there were 19,000 Italian emigrants; in 1879, 40,000; in 1887, 127,748, and in 1889, 218,412. Next comes Sweden with 75,561, in 1888; Austria and Hungary, with 48,567; Russia with 43,000; Norway with 21,452; and Denmark with 8659. In 1888 out of every 1000 inhabitants there migrated from Italy, 6.87; from Great Britain and Ireland, 7.46; from Germany, 2.10; from Sweden, 9.36; from Norway, 10.58. Hence proportionally to the population, the drain by emigration is greatest in the case of Norway. Emigration does not, however, threaten to deplete the population of Europe. Europe has never exhibited so rapid a growth of population as in the present century; and while Ireland, for instance, has since 1851 lost 71 per cent. of the average population, Ireland is still an over-populated country. The objection to emigration entertained by the governments of Europe is rather due to the fact, as Prof. J. Thorold Rogers declares, that emigration drains a country of its most vigorous, independent, and thrifty laborers—in fact, of the cream of its working population, while those that remain behind are more apt to be the unenterprising, the dissolute, and the idle.

Immigration into the United States.—The great majority of European emigrants seek the United States. The following figures for 1890 show the proportions to which this influx of foreign-born inhabitants has attained: from Great Britain, 122,085; Germany, 92,427; Italy, 52,003; Sweden, 29,632; Norway, 11,370; Europe not otherwise specified, 112,764; total for 1890, 455,302. The following table shows the comparative figures since 1820:

| Year. | Total Immigrants. | Year. | Total Immigrants. |
|------------|-------------------|------------|-------------------|
| 1820 | 8,385 | 1860 | 150,237 |
| 1830 | 23,322 | 1870 | 887,303 |
| 1840 | 84,066 | 1880 | 457,257 |
| 1850 | 369,986 | 1890 | 455,302 |

From 1820 to 1890 the population of this country was increased by 15,381,009 aliens.

Economic Effects of Immigration.—As in every great social movement, there are in immigration great economic gains to the country receiving it, as well as corresponding economic disadvantages. The remarkable growth of our country in its first century as a nation is very largely due to the constant additions to our laboring population received through immigration. Statistics show that the opening of the West and its agricultural productiveness have been in great measure the work of immigrants. In Minnesota, for example, fully one half of the agricultural population is composed of foreigners. In Michigan, in 1887, of some 90,000 farmers, more than 30,000 were of foreign birth. More than half the mining population of the entire country is alien, and so is a third of our manufacturing population. The children of immigrants, of course, do not appear in this estimate, but they must not be left out of sight. Another economic advantage is found by some in the actual money that most immigrants bring with them. It has been estimated that each immigrant brings on an average the sum of \$68.08; some have fixed the sum as high as \$100 per capita. (See Kapp, *Immigration*.) Taking even the more conservative of these two estimates, it would show a clear addition, for instance, in the year 1890, of some \$30,000,000 to the wealth of this country. It is probable, however, that this is fully offset, if not more than offset, by the remittances made every year to relatives in the old country by those who have made their home here. The statistics on this point are not complete, but it is known that in the year 1886 the sum of \$6,380,156 was thus remitted to Great Britain alone, and this is only a partial return. (See Smith, *Emigration and Immigration*, 1890.) It has also been very acutely remarked that, assuming even that each immigrant brings the larger sum (\$100), still the average well-being of our country is decreased, for the average wealth here is some \$1000 *per capita*, and the arrival of each new immigrant with only \$100 lowers the average. But the economic advantage seems to be clearly greater than the losses, in the case of able-bodied, intelligent, and industrious immigrants; and were all immigrants such, this question and other questions upon which we have to touch would not be raised.

Political Effects of Immigration.—So great an influx into a community like ours of men of foreign birth, training, and ideas, cannot be unaccompanied by serious political consequences, especially as our laws permit naturalization on the easiest possible terms, and after a probation that is often too short to allow the applicant to acquire our language. (See NATURALIZATION.) This is perhaps not unwise as a national policy, provided that immigration be permitted to continue. Any other policy, in fact, would lead to a well-defined class-system—in fact, to a servile system. We should have in the midst of the community a class of aliens bound to our institutions by no ties whatever, and feeling themselves to be a class apart. Of the great dangers of such a state of affairs it is unnecessary to speak. Hence, in the past, immigration has been unrestricted, and citizenship has also been a free gift burdened with scarcely any conditions. The result is a very large proportion of voters of foreign birth—a proportion larger than appears at first sight, because among immigrants there are always more adult males in proportion to their numbers than among a corresponding number of native-born persons. It is estimated that of the native-born white population, 22.4 per cent only are voters; while of the foreign-born white population, at least 46.3 have the suffrage.

This is a very important fact, and its political consequences depend, as do the economic consequences spoken of before, in large measure upon the character and quality of the immigrants who thus qualify themselves to hold the balance of power at all our elections, whether municipal, state, or national. So long as the bulk of the immigration to our shores was from English-speaking countries—from Ireland, Scotland, and England—the assimilation of it to the existing conditions of our civil polity was comparatively easy. A single generation sufficed to obliterate any distinctions between the families of the immigrants and the communities in which they made their home. The political traditions of personal independence and submission to law that they brought with them were the same as those that lie at the base of our own system. But since 1870 the statistics show that the great bulk of immigration has come from countries whose political development has been worked out upon far different lines, and whose subjects, moreover, by reason of their difference in language and social customs, have formed separate communities in which they have so far perpetuated and, if anything, accentuated these differences. Thus the Scandinavians have founded colonies of their own in Minnesota and Michigan; the Germans in Ohio; the Russians and Polish Jews in certain quarters of our great cities. Here they have their own society, their own schools and teachers, and newspapers printed in their own languages. The presence of communities such as this, alien in spirit and in habit of thought from the population surrounding them, is a great impediment to a thorough racial amalgamation, and is a source of weakness, threatening to render homogeneous and harmonious development impossible.

Unfortunately, in the past decade this truly alien immigration has steadily increased. Hungary, Russia, and Italy have sent us greater and greater numbers of their inhabitants with every year. In March, 1891, the Italians landing at the port of New York outnumbered the immigrants of any other nationality. The presence of so large an alien element is made evident in various ways: first, in the increase of those who exercise the suffrage with no true understanding of its real meaning and responsibilities; second, in the serious outbreaks of violence and disorder, such as the murders attributed to the *Maftia* (q. v.) in New Orleans, and the accompanying riot, as well as the outbreaks among the Hungarian miners in Pennsylvania (April, 1891); and, finally, the undoubted existence in our cities of a numerous element inspired here by the same principles and cherishing the same hatred of law and property as are confessed by the Anarchists of Germany, the Nihilists of Russia, and the Communists of France. How dangerous the presence of these agitators may become to a community was made evident by the Anarchist riots in Chicago, in 1886.

Social Effects of Immigration.—It is difficult to estimate with any degree of accuracy the direct social effects of immigration upon our people. The springs and sources of vice and crime are far too complex and too elusive to be mathematically treated. Yet it is quite possible to study tendencies; and so far as the statistics of disease, pauperism, and crime can be taken as evidence, the effects of immigration are distinctly unfavorable. This is, of course, largely due to the fact that the great mass of the immigrants come from the lower classes, and, as a high authority puts it, "it is always true that mortality is greater and crime, vice, pauperism, and illiteracy more prevalent among the lower classes than among the higher. It is only natural to expect, therefore, that the foreign-born will contrast unfavorably with the native population in all these respects, simply because they represent more numerous these lower classes."

Statistics show that about one-fifth of the persons susceptible to insanity are foreign-born; so are one-third of those suffering from chronic diseases, and one-fourth of the blind. In Massachusetts, in 1885, when only 27 per cent. of the entire population was foreign-born, 40 per cent. of the criminals were foreigners. In New York state, in 1887, there were in the country poor-houses 9172 native paupers and 9288 foreign paupers; while in the city poor-houses the native paupers were 18,001 as against 34,167 of foreign birth. Again, in the investigation of illiteracy, it was found in Massachusetts, in 1885, that of 122,263 persons above the age of ten years unable to read and write, 108,365 were foreigners. These figures are very striking, and justify the now very prevalent feeling that, with many material advantages, immigration, unrestricted, has introduced into our social system many elements that are, to say the least, most undesirable.

Chinese Immigration.—The immigration to this country of natives of China, and their social and economic relations to us, present such peculiar points of interest as to justify a separate consideration of the subject. The treaty negotiated between the United States and China, in 1868, by Mr. Anson Burlingame, and familiarly known as the Burlingame Treaty, contained the following explicit statement of the attitude of both countries regarding immigration and expatriation: "The United States of America and the Emperor of China cordially recognize the inherent and inalienable right of a man to change his home and allegiance; and also the mutual advantage of the free migration and emigration of their citizens and subjects respectively, from one country to the other, for the purposes of curiosity, of trade, or as permanent residents."

This treaty committed the United States to the principle of free intercourse between the two nations. After the passage of this treaty began a steady though not at first a very large influx of Chinese into this country, the majority of whom settled in the Pacific states, as laborers, miners, and traders. Between 1870 and 1880, some 40,000 Chinese arrived in American ports. (See SIX COMPANIES.) It was not long before their presence in American communities caused popular discontent. It was asserted that by their peculiar mode of living they were able greatly to underbid in the labor market workmen of the white races; that coming, as they often did, under contract as coolies, they formed a servile class; that they were subject to the jurisdiction of organizations of their own unrecognized by American law; that these secret tribunals exercised among them the power of life and death; that their presence lowered wages, deprived white labor of employment, and prevented immigration from other sources; that the Chinese were filthy in their habits, subject to leprosy and other loathsome diseases, immoral, obscene, spreading prostitution and introducing unnatural vices, so that they endangered alike the health and morality of the cities in which they made their home; and finally that their racial traits and peculiar civilization made it quite impossible that they should ever assimilate with the members of the Caucasian communities in which they lived. Many of these statements, while based upon the truth, are easily shown to have been grossly exaggerated. There is no proof that they do in reality form a servile class. Their personal habits compare in some respects favorably with those of the working classes of other races, and they certainly furnish a very small proportionate contribution to the number of known criminals. But, on the other hand, it was entirely true that some special vices, such as the use of opium and the practice of prostitution, were directly encouraged by the Chinese, while their inability to assimilate with the whites is undoubtedly a fact that admits of no question. This constituted a very serious objection to their continual immigration, for the enormous population of China, numbering

hundreds of millions, might send to our shores such a body of aliens as would outnumber in some parts of the country the native white population.

Because of these and other less reasonable considerations, it was not long before the white people of the Pacific states conceived an intense prejudice against all members of the Chinese race. This prejudice at first found expression in insults and violence, on the one hand, and in repressive and vexatious legislation on the other. As early as 1855, the California legislature imposed a tax of \$55 on every Chinese immigrant. In 1858 (this ten years before the Burlingame treaty) an act prohibited Mongolians from entering the state. In 1862 an act imposed a monthly tax of \$2.50 upon all Chinese except those engaged in the production of rice, sugar, tea, and coffee. All these acts were pronounced by the Supreme Court of California to be in violation of the constitution. In 1861 a tax was imposed upon all foreign miners, but was enforced against the Chinese alone. So, in San Francisco, a number of city ordinances were aimed directly at the Chinese inhabitants. Heavy license fees were imposed upon laundries; prisoners convicted of crimes were shorn (a disgrace to a Chinese); in 1863 it was enacted that the testimony of a Mongolian should not be received in any action in which a white man was concerned.

All these ordinances, and others to the same effect were rendered futile by the decisions of the Supreme Court of the United States, which held that any discrimination against the Chinese, as such, was illegal, because involving a violation of treaty obligations. It was, therefore, evident that relief could only come from action by Congress, and from this time the "Chinese Question" entered the sphere of national politics. In 1880 the Burlingame treaty was modified so as to allow the United States to limit the influx of the Chinese laborers, so soon as it should appear to be inimical to the national interests. In 1882 a bill originating in the Senate, and providing for the suspension of Chinese immigration for twenty years, was vetoed by President Arthur. A subsequent bill originating in the House of Representatives in the same year, and suspending Chinese immigration for ten years (1882-92), was signed by the president, and became law Aug. 5, 1882. Its provisions did not affect the free entrance to this country of merchants, professional men, or court officials; but as these form a very small proportion of the Chinese who come to the United States, the practical result of the bill has been to prevent the immigration of Chinese altogether; for the numbers of those entering the country fell, in the year 1882-83, from 35,614 to 381; and during the first six months of 1884 only 84 Chinese are known to have been admitted to our ports. Since then the law has been strictly enforced, though occasionally evaded by the smuggling of Chinese across the northern frontier from British Columbia.

The popular feeling against the presence of the Chinese has not been at all modified by their exclusion. Many deplorable acts of violence have been committed against them by mobs. In September, 1885, the Chinese laborers of Rock Springs, Wyoming, for refusing to join in a strike, were attacked by the white artisans; twenty-eight of them were murdered, and property valued at some \$150,000 was destroyed, for which the United States government subsequently indemnified the losers (1887). In 1888 a bill for the exclusion of the Chinese, much more sweeping than any that had hitherto been proposed, was passed by Congress, and signed by President Cleveland (Oct. 1). Its principal clause is as follows:

"Be it enacted, . . . that from and after the passage of this act it shall be unlawful for any Chinese laborer who shall at any time heretofore have been, or who may now or hereafter be, a resident within the United States, and who shall have departed, or shall depart, therefrom, and shall not have returned before the passage of this act, to return to or remain in the United States."

Restrictions upon Immigration; Pauper Immigration.—The right of a sovereign power to expel aliens or to refuse them admission has at all periods of history been exercised. It is inherent in the sovereignty of every nation, and is a part of the ordinary police power. It has been oftenest exercised against political offenders, even in republics. Thus in France, in 1849, a law gave the ministers the power of expelling aliens by a single decree. By the famous Alien and Sedition Law passed in the administration of President John Adams, the executive was authorized to exercise a similar power. Quite recently, so conservative a country as Great Britain expelled the anarchist Most. The government of Germany has since 1886 made wholesale expulsions of the Poles resident upon its eastern frontier. But the most sweeping legislation, intended to restrict immigration, is that of the United States, and is based not on political, but on social reasons. By the act of Congress passed in 1882, a head-tax was laid upon every immigrant by sea, and commissioners were appointed to inspect vessels entering American ports, who should have the power to prevent the landing of "any convict, lunatic, idiot, or any person unable to take care of himself or herself without becoming a public charge." Such persons were to be returned to the port whence they came at the cost of the owners of the vessels bringing them to this country. Under this act, the number of immigrants returned from the port of New York was, in 1883, 1350; in 1885, 1172; in 1888, 502.

A further law passed in 1885 makes it unlawful to prepay the transportation or to encourage in any way the immigration of aliens into the United States under contract or agreement to perform labor or service in the United States. The penalty for violating this act is a fine of \$1000 upon the persons themselves, and of \$500 upon the captain of

a vessel who knowingly transports the laborers. Exceptions are made in favor of actors, artists, lecturers, singers, domestic servants, or laborers skilled in industries not yet established in the United States. It has been held to apply to clergymen, a well-known clergyman in New York having been compelled to pay the full amount of the fine, as having violated the law in coming from England under contract to accept the rectorship of a city church. The object of this enactment, which has been several times amended and modified in the direction of greater strictness (in 1887, again in 1888, and in 1891), is to prevent a ruinous competition with American labor, resulting in an extension of the "sweating system" and an unnatural lowering of the normal standard of wages. It is likely that, as time goes on, even more rigorous measures will be taken to protect this country against the addition to its criminal and pauper classes—measures involving a system of consular inspection by representatives of our government in foreign countries.

Protection and Care of the Immigrant.—The first law passed by the United States to secure the health and safety of the immigrant was the act of 1819, providing against the overcrowding of passengers. This was amended and improved by the acts of 1855 and 1892. The first provision for the care of the immigrant after landing was made by the state of New York in 1824, followed by other measures in 1842, 1847, and 1855. In the last-named year Castle Garden was made a regular landing-place for immigrants, and provision was made for their instruction and protection. There their baggage was weighed and checked, their money honestly changed, and their friends communicated with. Ultimately a brokerage office, a post-office, a restaurant, wash-rooms, and a bureau of information were established, the use of which was free to all who landed. Many of the religious denominations established missions there. There is also a hospital for immigrants at Ward's Island well appointed and carefully managed. Commissioners appointed and paid by the state are in charge of the reception and distribution of the newly landed.

Bibliography.—The most recent as well as most satisfactory work on the general subject treated in this article is Prof. Richmond Mayo Smith's excellent study, *Emigration and Immigration* (1890). Other special works are: Bromwell, *History of Immigration into the United States* (1856); Geffcken, *Bevölkerungspolitik* (1886); *Report of the Emigration Commissioners of New York* (1889); *Emigration Statistics of Ireland* (1890); Leroy-Beaulieu, *De la Colonisation chez les Peuples Modernes* (1886); Seward, *Chinese Immigration* (1881); Whitney, *The Chinese and the Chinese Question* (1888); *Statistica dell' Emigrazione Italiana* (1891).

ÉMIGRÉS, the name given more especially to those persons who quitted France during the revolution. After the insurrection at Paris, and the taking of the Bastille, 14th July, 1789, the princes of the royal family departed from France. They were followed, after the adoption of the constitution of 1791, by all who considered themselves aggrieved by the destruction of their privileges, or who were exposed to persecution. Nobles quitted their châteaux; officers, with whole companies, passed the frontiers. Crowds of priests and monks fled to escape the oath of allegiance to the constitution. Belgium, Piedmont, Holland, Switzerland, and, above all, Germany, were overrun with fugitives of every age. Only a few had been able to save their property; the greater portion were in a state of destitution, and sank into utter demoralization. A court had formed itself round the princes at Coblenz; a government, with ministers and a court of justice, had been established, and communication was kept up with all the foreign courts unfavorable to the revolution. This conduct imbittered France, aggravated the position of the king, and drove the revolutionary party forward in their sanguinary career. Under the command of the prince of Condé, a body of É. was formed, which followed the Prussian army into Champagne. The result was that the severest laws were now put in force against the émigrés. Their lands were confiscated. The penalty of death was proclaimed against any one who should support or enter into communication with them. Thirty thousand persons were placed upon the list of É., and exiled forever from the soil of France, although many of them had refused to bear arms against their country. Not until after the failure of their attempt to land at Quiberon in 1795, did the É. abandon all thoughts of penetrating into France by force of arms. Condé's corps, after the peace of Luneville, was obliged formally to dissolve, and sought an asylum in Russia. Even under the directory, however, many had endeavored to obtain permission to return to France. The general amnesty proclaimed by the first consul was therefore joyfully hailed by the greater portion of the émigrés. Many, however, did not return home till after the downfall of Napoleon. Dignities, pensions, and offices were now showered upon these faithful adherents; but, according to the charter of 1814, they were unable to recover either their estates or their privileges. Finally, on the motion of the minister Villèle, the É. who had lost their landed estates, by the law of the 27th April, 1825, received a compensation of 30 million francs yearly on the capital of 1000 million francs. After the July revolution, however, the grant was withdrawn. Compare Antoine de Saint-Gervais, *Histoire des Émigrés Français* (3 vols., Paris, 1823), and Montrol, *Histoire de l'Emigration* (2d edit., Paris, 1825).

EMILIAN (or **ÆMILIAN**) **PROVINCES**, a name now employed to designate a portion of the recently formed kingdom of Italy, comprising the northern part of the states of the church (the Romagna), and the duchies of Parma and Modena. The name is derived from the ancient *Via Æmilia* (a continuation of the *Via Flaminia*, or great northern

road), which passed through these territories. The E. P. were formally annexed to Sardinia in April, 1860. See ITALY.

EMINENCE, a title given to cardinals by Urban VIII. Up to the period of his pontificate, they had been called most illustrious and most reverend. The assumption by the Roman Catholic clergy of this and other ecclesiastical titles, not having reference to any "pretended province, or to any pretended see or diocese," were not struck at by the English statute intended to prevent the assumption of certain ecclesiastical titles in respect of places in the United Kingdom. See ECCLESIASTICAL TITLES ASSUMPTION ACT.

EMINENT DOMAIN, the original ownership retained by the state, by which land or other private property may be taken for public use or benefit. It is the highest and most exact idea of property remaining in the government, or in the aggregate body of the people in their sovereign capacity, giving the right to resume possession in the manner directed by law. If the proper authorities propose to open a street, or charter a railroad, or set apart land for a park, or for any lawful and reasonable purpose, and the owner of lands in the route or space desired refuse to sell or ask an unreasonable price, the state by eminent domain has the power of control, and process may be issued from a court having authority to compel the surrender of the property. The constitution of the United States limits the exercise of this right to cases where the public good demands it, and requires compensation to those from whom the property is taken. These conditions are also named by many of the state constitutions.

EMIN PASHA. This name, now so well known throughout the world, is the title adopted by Edouard Schnitzer, a German, born in the town of Oppeln, Prussia, March 28, 1840, of Protestant parents. He studied medicine in Breslau, Berlin, and Königsberg. At an early age he entered the service of Ismail Hakki Pasha, once governor-general of Scutari, and a Mushir of the empire, and with him went to Armenia, Servia, and Arabia. In 1860 he was made surgeon in the Turkish army. He became attached to the "Young Turk" or reform party in Stamboul, the organ of which, for its boldness in the reform interest, was suppressed three times by the authorities. On its last suppression Emin was expelled from the country. On the death of his patron he went to Niesse, where his mother and sisters lived, and in 1875 went to Egypt. He was in Constantinople at the time of the assassination of the Sultan Abdul Aziz, being one of the advisers of Midhat Pasha (q.v.), the prime-minister. He was at this time only a civilian pasha, receiving pay during the time employed. When the prime-minister was dismissed, at the time of the last Russian-Turkish war, Emin went to Asia. He joined a caravan and, passing through Suakin, made his way to Khartoum. Much reduced in circumstances, he procured an introduction to Gen. Gordon, who gave him a billet as storekeeper, and afterwards appointed him doctor. Later he was given the position of surgeon-general on Gen. Gordon's staff (1876). His time was fully occupied, as besides his regular duties he wrote elaborate papers on scientific subjects, accumulated masses of scientific matter, collections, etc., and was sent on important missions to Uganda and Unyoro. He was an expert linguist, being familiar with Turkish, Arabic, German, French, Italian, English, and many African dialects. When Gen. Gordon went to Khartoum as Governor-General he sent Emin to rule the Equatorial Provinces (1878). In three years he succeeded in driving out the slave-traders; where there was a deficiency in the revenue he created a surplus; conducted his government on the lines of Gen. Gordon's ideas, and was withal modest, retiring, and conscientious. When the Mahdi's (q.v.) rebellion broke out and everything was in confusion, Emin remained at his post. At Khartoum, Hicks's army was massacred, the Egyptian garrison at Soudan was abandoned to its fate, and Gen. Gordon was left to perish while awaiting relief from the expedition sent out, which was slowly creeping up the Nile, and which arrived too late. When Egyptian rule was finally wiped out by the English in other sections, the Equatorial Provinces were forgotten, and Emin was left to depend upon his own resources. Had he chosen to leave behind him helpless women and children, who looked to him for protection, and abandon his people to the horrors of slavery, he could easily have cut his way out. But he did not make the desertion of himself by the Egyptian government a pretext for his desertion of them. He had 4000 troops, and he immediately organized a body of native soldiers; lacking money, he still managed to maintain his position and govern the country. He taught the natives to raise cotton, rice, indigo, and coffee, weave cloth, make shoes, candles, soap, etc. He vaccinated the natives for small-pox, and opened the first hospital in the country. He established the first post-office, and a post route with forty officers. He organized expeditions and made important geographical discoveries in the region of Albert lake, and in every way demonstrated his capability for governing barbarian tribes. The last European whom he met before Stanley was Dr. Junker, from whom he parted Jan. 1, 1886. From that date until he received tidings of Stanley, in 1887, communication was irregular and infrequent. In Nov., 1887, he went to lake Albert, hoping to see him, not knowing whom he was to meet, having only recently heard that a white man was in the country. After eight years of comparative silence, without books, periodicals, or regular news, and for five years, until 1888, without supplies, except such as he produced himself, he naturally longed for tidings. As a scientific man he had found much to interest him, and, being ambi-

tious, almost involuntarily he was thrust forward to the command of the Equatorial Provinces. Absorbed in his pursuits, it is rather remarkable that previous to meeting Stanley he had never even visited the south end of lake Albert. His first encounter with the relief expedition was on May 1st, 1888, at Kavalli's, when the first installment of arms, ammunition, etc., was handed to him, and Stanley left him, May 23, with the expectation of again meeting him preparatory to starting for home. The Pasha had the utmost confidence in his people, believing that those to whom he had devoted himself for so many years, and whose condition he had so greatly improved, could not be disloyal to him. He trusted them too fully, and he awoke from his dream too late. They looked down upon him as a bird collector, without any respect. While he has many fine traits of character, and there is much to admire, he was more devoted to his botanizing, entomologizing, geologizing, and ornithologizing than to his duties as a governor, and loved the title of M.D. more than that of Pasha. With immense energy for teaching his people agriculture, manufactures, etc., he lacked the decision required to command his troops; hence, when trouble came he was unprepared for it. Many reports were circulated to the effect that Stanley was only an adventurer, whose aim was to aid the Pasha in crushing the people and reducing them to slavery. On the fall of Khartoum some of the most influential chiefs incited the people to rebellion, and Emin was deposed and made a helpless prisoner, with the prospect of being taken to Khartoum. Plans were laid by them to entrap Stanley on his return to lake Albert, but these proved unsuccessful. The Pasha was freed in Nov. of the same year, and although attacked by the Dongola, he was able to repulse them. This solitary man was engaged in a task as impossible as that of Gen. Gordon's; while he showed much bravery, his officers were plotting treason, and it was found that nothing could inspire him with the idea that his case was hopeless; he was serene and resigned, and very undecided as to his movements. While Stanley was waiting impatiently for his answer as to whether he would return with him to Egypt, he was waiting to learn if his people were willing to go with him; if not, he would remain. On Feb. 17 Emin again reached Kavalli's, and on April 1, when ready to make the first move towards home, only four of his people were ready to go with him. While the expedition was sent out to relieve the distressed condition of Emin Pasha, he was still at liberty to remain in Africa if he desired. Three propositions were made to him: He might return to Egypt, receive the payments due him, and still act under orders from the Egyptian government. By king Leopold of Belgium he was offered the command of the Equatorial Provinces, with the understanding that he was to keep open communication between the Nile and Congo, and maintain law and order. And, thirdly, Stanley desired him to establish the East African Association. In the mean time, he had offered his services to the British East India Company. A meeting was finally arranged at Bagamoyo, Dec. 4, 1889, and, amid general joy and feasting, an unfortunate accident occurred by which Emin, in falling from a veranda, was seriously injured. Stanley was obliged to leave him in the hospital, and set out for home, Dec. 6, 1889. The Pasha recovered entirely, sent his resignation to Cairo, and finally accepted a position in the service of the German East Africa Company. While holding this post he was killed by the natives in 1892.

EMIR, an Arabic word, equivalent to "ruler," is a title given in the east, and in the n. of Africa, to all independent chieftains, and also to all the actual or supposed descendants of Mohammed through his daughter Fatima. The latter are very numerous throughout the Turkish dominions, but although entitled by birth to be classed among the first four orders of society, they enjoy no particular privileges or consideration; on the contrary, they are found engaged in all sorts of occupations, and are to be met with among beggars, and the lowest of the populace, as frequently as among the molahs. Their privileges are confined to a few unimportant matters, chiefly to the exclusive right to wear turbans of a green color, that having been the favorite color of the prophet. They are placed under the supervision of the emir-beshir. In former times, the title of emir was borne by the leaders in the religious wars of the Mohammedans, as well as by several ruling families, such as the Thaherides and Samanides in Persia, the Tulunides in Egypt, the first seven Ommaïades in Spain. The title emir, in connection with other words, likewise designates different offices. *Emir-al-Mumenin*, "prince of the faithful," is the title assumed by the caliphs themselves; *emir-al-muslem*, signifying the same thing, was the title of the Almoravides. *Emir-al-Omrah*, "prince of princes," was the title of the first minister, under the caliphs and the East Indian Moguls, who united in his own person the highest civil and military dignities. It is now the title of the governors of different provinces. The Turkish master of the horse is styled *emir-achor*; the standard-bearer, *emir-alem*; and the leader of the caravans of pilgrims to Mecca, *emir-hadji*. *Ameer* is another spelling of the word.

EMMANUEL, EMANUEL, or IMMANUEL, a Hebrew name, whose signification—"God with us"—is not, by itself, proof that he to whom it would be given was divine. This and similar combinations of divine names were, and still are, in ordinary use among Jews. But the evangelist Matthew (i. 23) applies it in a special manner to the child Jesus; and the whole history of the nativity is in harmony with the special application. Some Christian interpreters consider that the reference (Is. vii. 14) to the birth of the Messiah is direct and exclusive. But the prophecy itself and the circumstances in which it was spoken evidently call for a speedy fulfilment according to the ordinary laws of nature, the virgin being one whom the prophet was commanded then

to marry, and her son the child spoken of, under another name, in the eighth chapter. Yet, besides this, as many interpreters believe, the prophecy was designed to have a secondary and full accomplishment in the miraculous conception and birth of Jesus Christ from his virgin mother. This is proved not simply by Matthew's application of the prophecy and by the New Testament account of the nativity, but also by the whole subsequent exhibition of the character and work of Jesus in attestation of his claim to be the incarnate Son of God.

EMMANUEL, surnamed **THE GREAT**, 1469-1521, King of Portugal, was the son of Ferdinand, Duke of Viséu. He succeeded John II. in 1495. Portugal attained her greatest glory and power during his reign, through the discoveries and expeditions of Vasco da Gama, Almeida, and Albuquerque, though he, as king, contributed very little to it. In order to win Isabella of Castile for his wife he banished the Moors and Jews, though they were the richest and most useful class of people in the kingdom.

EMMANUEL COLLEGE, CAMBRIDGE, was founded in 1584 by sir Walter Mildmay, chancellor of the exchequer and privy-councilor in the reign of queen Elizabeth. The foundation fellowships are thirteen in number. These fellowships are open to all her majesty's subjects, and a candidate becomes eligible to them on proceeding to the degree of B.A. or any equivalent degree. All the foundation fellows are obliged to proceed regularly to the further degree in arts, law, medicine, or any other faculty they have selected. There must be four of them always in priest's orders; and any who are not tutors or bursars in the college, are bound to be in orders at the end of the seventh year of their fellowship, at the risk of forfeiting it three years afterwards. The college also possesses two fellowships and four scholarships on sir Wolstan Dixie's foundation (but the Dixie fellows have no voice in college affairs, nor any claim to the offices or dividends of the college). The patronage of the college consists of 24 benefices, situated in the eastern and south-western counties of England; and of two schools, one in Norfolk, and the other in Suffolk. This college had, in 1896, 162 undergraduates.

EMMANUEL PHILIBERT, surnamed the **IRON-HEADED**, 1528-1580, Duke of Savoy, was one of the most able generals of his time. He entered the service of Charles V., and on the abdication of that emperor, was made governor of the Low Countries. In 1557 he gained a great victory at Saint-Quentin, and in 1574 he secured the evacuation of Piedmont, where he ruled wisely until his death.

EMMENAGOGUES, medicines intended to restore, or to bring on for the first time, the menstrual excretion in women. The E. chiefly in use are the preparations of aloes, iron, myrrh, and other stimulants in connection with purgatives; and also the local use of the warm bath, leeches, fomentation, etc. Some recommend still more powerful and direct applications to the uterine mucous membrane; as galvanic pessaries, lunar caustic, scarifications, etc.; but these are not in general use. See **MENSTRUATION**.

EMMENS, STEPHEN H., scientist, b. Kent, England, Dec. 27, 1843; educated at King's college, London; studied chemistry and mining and electrical engineering; invented the giant explosive known as emmensite, also a method of converting old ordnance into effective guns; obtained the X-rays with the aid only of sunlight; and, Jan. 1, 1897, sent a memoir to the Smithsonian Institution, the *Académie des Sciences* of Paris, and the Royal Society of London, detailing an original theory of natural law in opposition to Newton's law of gravitation.

EMMENSITE. See **EXPLOSIVES OF HIGH POWER**.

EMMERICH, a t. of Rhenish Prussia, is situated on the right bank of the Rhine, on the borders of Holland. It is a very old town, and has a Dutch character of cleanliness. It has a custom-house, an orphan-house, a gymnasium, and several churches. Pop. '90, 9622.

EMMET. See **ANT**.

EMMET, ROBERT, 1780-1803; b. Dublin, a school-fellow and college-mate of Moore, the poet. Both were members of the historical society, and ardent champions of the cause of freedom for Ireland. In 1798, Emmet was expelled from the university on account of his connection with the United Irishmen. He went to the continent, where he remained until 1802; then returned secretly to Dublin and endeavored to plan a general revolution. July 23 of that year, he made an attempt to seize the arsenal and city of Dublin; but his mob of followers created scarcely a serious riot, flying in panic at the first firing by the police. Finding his revolution a miserable failure, Emmet hid himself in the Wicklow mountains, intending to escape to the continent, but he delayed long enough to have an interview with the daughter of Curran, the famous advocate, with whom he was in love, and this delay led to his arrest. He was tried for treason, convicted, and executed Sept. 20, 1803. His speech, on being asked why sentence should not be pronounced, has long been held up as a model of patriotic eloquence.

EMMET, ROSINA, was born in New York City, Dec. 13th, 1854. She is best known as an illustrator of popular books, and as the winner of a prize of \$1000 offered by Prang for a design.

EMMET, THOMAS ADDIS, LL.D., 1764-1827, b. Cork; brother of Robert. He was educated in Trinity college, Dublin, and studied medicine in Edinburgh, and visited the medical schools of the continent. In 1788 he gave up medicine, and took to the study

of law being admitted to the Dublin bar in 1790. He was involved as counsel and as leader of the United Irishmen, and in Mar., 1798, he, with others, was arrested. He was kept a prisoner until June, 1802, and then received freedom on agreeing to leave the country. He went to Hamburg and to Brussels, and, in 1803, to France, where he had an interview with Napoleon, who was at that time contemplating an invasion of England. In 1804 he went to New York, where he soon gained a large law practice, and received much attention as a political exile. In 1812 he was attorney-general of New York state, but served only six months.

EMMET, THOMAS ADDIS, physician, b. in Virginia, in 1828; graduated at the Jefferson medical college, 1850; was assistant surgeon and surgeon-in-chief at the Woman's hospital, New York, in 1855-72; afterward became a specialist on diseases of women, introducing important operations and treatment, and writing much on the subject. In 1896, his unique collection of works on American history, gathered at a cost of \$300,000, was presented to the New York public library, through the generosity of John S. Kennedy. He received the Letare gold medal of the university of Notre Dame in 1897.

EMMET, a co. in n. Iowa, on the border of Minnesota; 408 sq. m.; pop. '90, 4274. It is undulating, with fertile soil, and contains a number of small lakes. Co. seat, Estherville.

EMMET, a co. in n. Michigan, in the peninsula bordering on Mackinaw straits and lake Michigan, traversed by the Grand Rapids and Indiana railroad; 438 sq. m.; pop. '90, 8756. The surface is undulating and the soil fertile, mostly of prairie; productions agricultural. Co. seat, Harbor Springs.

EMMITTSBURG, a borough in Frederick co., Md., 49 miles n.w. of Baltimore, by the Western Maryland railroad, and 10 m. s.w. of Gettysburg, Penn. It is noted principally as the seat of Mount St. Mary's college, one of the largest Roman Catholic educational institutions in the United States, established in 1809. Near by is St. Joseph's academy, the mother-house of the sisters of charity in the United States. Pop. '90, 844.

EMMONS, a co. in N. Dakota; formed 1879. Pop. '90, 1584. Co. seat, Williamsport.

EMMONS, EBENEZER, 1799-1863; b. Mass.; professor of natural history in Williams college, 1833, and of chemistry in Albany medical college, 1838. In 1836 he was one of the commission to make a geological survey of New York, and in 1856 became state geologist of North Carolina. He wrote text books and reports on mineralogy and geology.

EMMONS, GEORGE FOSTER, b. Vt., 1811; midshipman, 1828, and rose to rear-admiral in 1872. He was in the Wilkes exploring expedition, and off the Mexican coast during the war with that country. In the war of the secession he commanded blockading vessels, and was in Dahlgren's fleet; and from 1864 to the close of the war he commanded a division of the blockading fleet in the gulf of Mexico. He d. 1884.

EMMONS, NATHANAEAL, D.D., was b. at East Haddam, Conn., in 1745, and graduated at Yale college, in 1767. In 1773 he was ordained pastor of the Congregational church in Franklin, Mass., and continued in the office 54 years. He superintended the studies of nearly 100 young men in preparation for the ministry, many of whom became strong and useful preachers. He was one of the originators of the Mass. missionary society, and one of the editors of its missionary magazine, from which the *Missionary Herald* grew. When masonry was popular he zealously opposed it; when the anti-slavery movement was denounced he actively favored it. He was a decided "Federalist," and caused great excitement by his political writings. As an author and preacher he exerted a very great influence on the churches. During his life he published 4 elaborate dissertations, more than 100 magazine articles, and about 200 sermons, of which 7,000 copies were issued. At his death a part of his sermons was published in 7 octavo volumes, and a new edition, enlarged, in 6 volumes. About 75 years of his life were spent in earnest and systematic study, during the greater part of which time he read and wrote 10, 12, and sometimes 14 hours a day. He has been described by those who knew him well as "methodical, temperate, regular in his habits, distinguished for punctuality, precision and sharpness of mind, keen analysis, self-consistency, wit, frankness, honesty, and reverence for the truth." As a Calvinist he wished to be considered neither "high" nor "low," but consistent. On one Sabbath he would present the doctrine of divine sovereignty with such strength that some might think him a fatalist; the next Sabbath he would advocate free will so powerfully that some might call him a Pelagian; and in a third sermon he would lay out his strength in showing that the sovereignty of God was not inconsistent with the free agency of man. He steadily adhered to old usages, and wore the antique dress and three-cornered hat as long as he appeared in public. He retained the strength of his faculties to the last, and died in 1840, with an unflinching faith in Christ.

EMOLLIENTS (from Lat. *mollis*, soft), substances used to soften the textures to which they are applied, as poultices, fomentations, etc., externally, and demulcents (q.v.) internally.

EMORY, JOHN, D.D., 1789-1835; b. Md.; brought up to the law, but became a Methodist preacher in 1810. In 1820 he was a delegate to the British Wesleyan conference; in 1824, book agent of his church at New York, and in 1832 was chosen bishop. He

wrote *The Divinity of Christ Vindicated; Defense of our Fathers*; and other works on religious subjects.

EMORY, ROBERT, D.D., 1814-48; son of John; president of Dickinson college; author of a life of his father, and *History of the Discipline of the Methodist Episcopal Church*.

EMORY, WILLIAM HEMSLEY, B. MD., 1811; a graduate of West Point; in 1863, col. of cavalry, and in 1865, maj.-gen. of volunteers. He served with credit in the Mexican and civil wars, and was retired, with rank of brig.-gen., 1876; d. 1887.

EMOTION. This is the name for one of the comprehensive departments of the human mind. It is now usual to make a threefold division of the mind—E., or feeling; volition, or action prompted by feelings; and intellect, or thought. It is not meant that these can be manifested in absolute separation; or that we can be at one time all E., another time all volition, and again all thought, without either of the other two. But although our living mind is usually a concurrence, in greater or less degree, of all of them, still they can be distinguished as presenting very different appearances, according as one or other predominates. Wonder, anger, fear, affection, are emotions; the acts that we perform to procure pleasurable feelings, and avoid painful, are volitions, or exercises of will; memory and reasoning are processes of thought, or intellect.

E. is essentially a condition of the waking, conscious mind. When asleep, or in a faint, or in any of those states called "being unconscious," we have no E.; to say that we have would be a contradiction, which shows that "emotion" is a very wide and comprehensive word. In fact, whenever we are mentally excited "anyhow," we may be said to be under emotion. Our active movements and intellectual processes can sometimes go on with very little consciousness; we may walk and scarcely be aware of it; trains of thought may be proved to have passed through the mind while we are unconscious of them. Now, it is these unconscious modes of volition and intellect that present the greatest contrast to E.; showing how nearly co-extensive this word is with mental wakefulness, or consciousness, in its widest signification.

E., then, is of the very essence of mind, although not expressing the whole of mind. There are three distinct kinds or divisions of it: pleasures, pains, and excitement that is neither pleasurable nor painful.

Every kind of pleasure is included under E. in its widest acceptance. The pleasures of the senses are as much of an emotional character as those pleasures that are not of the senses—as, for example, those of power, pride, affection, malevolence, knowledge, fine art, etc. Every one of our senses may be made to yield pleasurable E.; and all those other susceptibilities, sometimes called the special emotions, of which a classification is given below, are connected with our pleasures or our pains. What pleasure is in its inmost nature, each one must find from his own experience; it is an ultimate fact of the human consciousness which cannot be resolved into anything more fundamental, although, as will be seen, we can lay down the laws that connect it with the other manifestations of mind—namely, action and thought, and with the facts of our corporeal life.

In the next place, pain is a species of emotion. We know this condition as being the opposite of pleasure, as the source of activity directed to its removal or abatement, and as the cause of a peculiar outward appearance, known as the expression or physiognomy of pain. All the inlets of pleasure are also inlets of pain. The various sensibilities of the mind, whether the outward senses, or the more inward emotions, give rise at one time to pleasure, at other times to pain, the conditions of each being generally well understood by us; we can define the agencies that cause pleasure or suffering through the skin, the ear, or the eye.

But it is requisite, further, to recognize certain modes of neutral excitement, in order to exhaust the compass of emotion. We are very often roused, shocked, excited, or made mentally alive, when we can hardly say that we are either pleased or put to pain. The mind is awakened and engrossed with some one thing, other things are excluded; and the particular cause of the excitement is impressed upon us so as to be afterwards remembered, while all the time we are removed alike from enjoyment and from suffering. This is a kind of E. that has its principal value in the sphere of intellect. The E. of wonder or astonishment is not seldom of this nature; for although we sometimes derive pleasure, and sometimes the opposite, from a shock of surprise, we are very frequently affected in neither way, being simply *impressed*. The strange appearance of a comet gives far more of this neutral effect than of the others. It is a thing that possesses our mind at the time, and is afterwards vividly remembered by us, and these are the chief consequences of its having roused our wonder.

The physical accompaniments of E. are a part of its nature. It has been remarked in all ages, that every strong passion has a certain outward expression or embodiment, which is the token of its presence to the beholder. The child soon learns to interpret the signs of feeling. Joy, grief, affection, fear, rage, wonder, have each a characteristic expression; and painters, sculptors, and poets, have adopted the demeanor of passion as a subject for their art. There must be some deep connection in the human

frame between the inward states of consciousness and the physical or corporeal activities, to produce results so uniform throughout the human race. When we study the facts closely, we obtain decisive proof of the concurrence of the following members and organs in the manifestation of feeling.

In the first place, the *muscles* or *moving organs* are affected. Under strong excitement, the whole body is animated to gesticulation; in less powerful feelings, the expression confines itself more to the *features* or the movements of the face. These last have been analyzed by sir Charles Bell. The face has three centers of movement—the mouth, eyes, and nose; the mouth being most susceptible, and therefore the most expressive feature. In the eyes, expression is constituted by the two opposite movements of the eyebrows; the one raising and arching them (prompted by a muscle of the scalp, *occipito-frontalis*), the other corrugating and wrinkling them. The one movement is associated with pleasing states, the other with painful. The nose is acted on by several muscles, the most considerable of which is one that raises the wing together with the upper lip, and is brought into play under the disgust of a bad smell and in expressing dislike generally. The mouth is principally made up of one ring-like muscle (*orbicularis*), from which nine pairs radiate to the cheeks and face. In pleasing emotions, the mouth is drawn out by the action of two pairs of muscles, named the buccinator and zygomatic, situated in the cheek. The expression of pain is determined by the contraction of the aperture of the mouth, through the relaxation of those muscles, and the contraction of the ring-like muscle that constitutes the flesh of the lips; and by two muscles in the chin, one depressing the angle of the mouth, and the other raising the middle of the lower lip, as in pouting. Besides the features, the voice is instinctively affected under strong feelings; the shouts of hilarious excitement, the cry of sharp pain, and the moan of protracted agony, are universally known. Another important muscle of expression is the diaphragm, or midriff, a large muscle dividing the chest from the abdomen, and regularly operating in expiration. In laughter, this muscle is affected to convulsion.

In the second place, the *organic functions* of the system are decidedly influenced for good or evil under emotion. The glandular and other organs acted on in this way comprehend the most important viscera of the body. The lachrymal secretion is specifically affected under passion; the flow of tears being accelerated to a rush, instead of pursuing the tranquil course of keeping the eyeball moist and clean. The states of the sexual organs are connected with the strongest feelings of the mind, being both the cause and the effect of mental excitement. The digestion is greatly subject to the feelings, being promoted by joy and hilarity, not in too great excess, and arrested and disturbed under pain, grief, terror, anger, and intense bodily or mental occupation. The skin is known to respond to the condition of the mind; the cold sweat in fear is a derangement of its healthy functions. The respiration may be quickened or depressed according to the feelings. The action of the heart and the circulation of the blood are subject to the same causes. The nature of this influence was explained under BLUSHING. Lastly, in women, the lacteal secretion participates in the states of E., being abundant, healthy, and a source of pleasure in a tranquil condition of mind, while grief and strong passions change it to a deleterious quality.

The connection between mental E. and bodily states being thus a fact confirmed by the universal experience of mankind, can we explain this connection upon any general law or principle of the human constitution? Have we any clue to the mysterious selection of some actions as expressing pleasure, and others as expressing pain? The reply is, that there is one principle or clue that unravels much of the complexity of this subject—namely, that *states of pleasure are usually accompanied with an increase in some or all of the vital functions, and states of pain with a depression or weakening of vital functions*. This position may be maintained on a very wide induction of facts, many of them very generally recognized, and others open to any careful observer; there being, however, some appearances of an opposite kind, which have to be satisfactorily accounted for, before we can consider it as fully established.

If we consider first the respective *agents* or causes of pleasure and pain, we must acknowledge that they are very generally of a nature to accord with the view now stated. How many of the sources of pleasure are obviously sources of increased energy of some vital organs. The cause of food is too obvious to need any comment. Warmth within limits both confers pleasure and stimulates the skin, the digestion, and other functions. Fresh air exhilarates the mind, while quickening the respiratory function. Light is believed to stimulate the vital actions no less than the mental tone. And if there be some pleasures of sense, such as mere sweetness of taste, fragrant odors, music, etc., that do not obviously involve greater energy of vital function, they might be seen to do so, if we knew more than we do respecting the operation of the various organs, and we are certain that they do not have the opposite effect. Medical authorities are so much impressed with the general tendency of pleasures, that they include them in the list of *stimulants* in cases of low vitality. If we pass from the senses to the special emotions, such as wonder, power, tender affection, taste, we find that when those are pleasing, they also increase the animal forces at some point or other. A stroke of victory sends a thrill through the whole system; and if the pulse were examined at that moment, we should find that it beats stronger. The illustration for pains is exactly parallel, but still more striking. It is notorious that hurts, wounds, fatigue, ill-health, hunger, chillness,

nauseous tastes and odors, the silence of a prison, the gloom of utter darkness, failure, humiliation, contumely, deprivation of one's usual comforts and pleasures—while causing pain, cause in a corresponding degree a depression of the powers of the system. There are some apparent exceptions, as in the stimulus of the whip, the bracing agency of cold, and the effect of misery generally in rousing men from lethargy to action, but these could all be shown to be quite compatible with the main principle.

If we turn from the agents to the *expression*, or modes of manifestation, of the opposing mental conditions, we shall find that the facts are of the same general tenor, although with some seeming exceptions. Joy makes a man spontaneously active, erect, animated, and energetic. It is as if a flush of power were diffused through his members; and the efforts he is then prompted to, lead to no painful exhaustion. The opening up of the features, by the elevation of the eyebrows and the retraction of the mouth, indicates that the stream of energy has coursed over the face. In a still greater shock, the convulsiveness of laughter, by which respiration is quickened, attests the superabundance of the animal spirits. The body stands more erect, and every act done is done with more emphasis. Grief and depression are the opposite in every particular. The frame is languid and stooping, the features lifeless, the voice is a feeble wail; and although there is a species of convulsion attending on this condition of mind, it is a marked contrast to the other. The sob is caused by the *partial paralysis* of the diaphragm, which necessitates great voluntary efforts in order that the breathing may proceed. The choking sensation at the throat is also a species of paralysis from loss of vital power. The convulsions arising under such circumstances are productive of an exhausting reaction, which is the case with all the energetic movements stimulated by extreme pain.

Such is undoubtedly the general fact. But why should pain stimulate, or give strength to, *some special* muscles, such as the corrugator of the eyebrow, and the depressor of the angle of the mouth? This has appeared a great difficulty to the ablest physiologists. It would look as if pleasure coincided with an energetic wave sent to some muscles, and pain with an energetic wave sent to others; so that the opposite conditions of mind are equally accompanied by an accession of power to some bodily member. But if we examine the matter more narrowly, it will probably turn out that the muscles that seem to be stimulated under pain, are not so in reality, but obtain the upper hand through the general relaxation of the system. Thus, take the mouth. We know the state of the mouth in languor, inaction, and sleep. We know that when we are roused in any way, the muscles of the face operate and draw the mouth asunder in a variety of forms. Pleasure corresponds with our energetic moods, pain causes a collapse towards the sleepy and exhausted condition which represents a state of departed energy. So the collapse of the body might seem an exertion of the *flexor* muscles, or those that bend the frame forward; but we are well aware that such collapse takes place when the system is totally lifeless. A renewed energy, as a matter of course, makes us stand erect.

This is a part of the case in reply to the objections arising from a specific expression of pain, but not the whole; and the answer to the difficulties still remaining is furnished by a fact that, if well authenticated, will probably dispose of nearly all the exceptions to the general principle now contended for. It is the organic functions, *more than the muscular system*, whose increased vitality coincides with pleasurable feeling, and their diminished action with pain. Muscular exercise is often highly agreeable, but the pleasure of *resting* after exercise is still more so. Now, there can be little doubt that what happens in the state of healthy repose is this: the amount of vital force stimulated by exercise—the increased energy derived from plying the lungs and heart—is now allowed to leave the active members, and to pass to the other organs—the digestion, skin, and various secreting glands—and it is their aggrandizement that is associated with the comfortable sensations of repose and sinking into sleep. Thus, the abating of muscular energy may be a cause of pleasure, provided the organic functions are raised in consequence; but it may be maintained as a highly probable supposition, that a certain health and energy of some or all of these functions (it is difficult to draw a specific line) is essential to pleasurable feeling. We may doubt whether even mental causes can materially raise the tone of enjoyment, if they do not also raise the activity of some of these organs. Not only may a person be very happy and comfortable in the prostration of the muscular energy, even in a sick bed, but one way of procuring comfort is to induce a total inaction of the moving members, to allow all the available nervous power to pass to the viscera and secretions. Hence a *forced relaxation* of the muscles *generally*, by the employment of *some* of them, is a means of soothing the mind under pain. Thus, the active intervention of certain small muscles—such as the corrugator of the eyebrows, the orbicular muscle of the mouth, and the depressor of the angle of the mouth—by relaxing a much greater body of muscle, is the means of setting free vital energy for behoof of the other parts of the system. This would explain the mental relief furnished by an assumed sadness of feature, and a voluntary collapse of the body generally.

It would appear, then, that the stimulus of muscle is not necessarily or immediately a cause of pleasure; while the stimulus of the organic functions is so. Thus, a bracing cold quickens the activities, but is apt to cause a shock of pain, by temporarily checking the action of the skin; when the reaction arrives, this check is converted into stimula-

tion, and the mental state is altered in like manner. A bitter tonic must be supposed to act on the same principle.

The emotions of the human mind may be classified under two heads:

First—The pleasures, and pains, and modes of excitement growing out of the exercise of the senses, the movements, and the appetites. See SENSES. The five senses, commonly recognized, are partly sources of pleasure and pain, in which case they yield emotion, and partly sources of knowledge, by which they are related to the intellect. There are other sensibilities not included in the five senses, but ranking with them in those particulars—as the feelings of muscular exercise and repose, and the sensations of digestion, respiration, etc.

The second head comprises the special emotions not arising immediately out of sensation, although connected therewith. These have been variously classified. The following is one mode of laying them out: 1. Feelings of liberty and restraint; 2. Wonder; 3. Terror; 4. Tender affections; 5. Emotions of self-complacency, love of approbation, etc.; 6. Sentiment of power; 7. Irascibility; 8. Emotions of action, including the interest of pursuit or plot; 9. Emotions of intellect, love of knowledge, consistency, and inconsistency; 10. Fine art emotions, or taste; 11. The moral sense.

On this subject, see Müller's *Physiology, Movements due to the Passions of the Mind*; Bell's *Anatomy of Expression*; Stewart on the *Active Powers*; Bain on the *Emotions and the Will*, etc.

EMPANEL, or **IMPANEL**. In law this word is used with entirely different significations in English and American practice. In the first it denotes the entering upon a schedule or roll, by the sheriff, of the names of a sufficient number of jurors to serve on the grand and petty juries; in the American practice the term applies usually to the list of jurors drawn for the trial of a particular case, and the court is said to empanel the jury by calling those thus selected to the jury box, passing upon their qualifications and swearing them in. But occasionally in courts in this country the word is used in the English acceptance.

EMPECINA DO, DON JUAN MARTIN DIAZ, EL, one of the leaders of the Spanish revolution of 1820, was b. in 1774. He was the son of poor parents, and entered the Spanish army in 1792. At the head of 5,000 or 6,000 men, he carried on a guerilla warfare against the French during the Peninsular struggle, and acquired great distinction. In 1814, he was appointed col. in the regular army, and the king himself created him field-marshal; but in consequence of petitioning Ferdinand, in 1815, to reinstitute the cortes, he was imprisoned, and afterward banished to Valladolid. On the outbreak of the insurrection in 1820, he took a prominent part on the side of the constitutionalists, and on several occasions exhibited great courage, daring, and circumspection. In 1823, after the triumph of the absolutists, he was arrested, exposed in an iron cage to the contumely of the passers-by, and finally executed on a common gibbet, amidst the ferocious yellings of a debased and liberty-hating populace.

EMPEDOCLES, a Greek philosopher of Agrigentum, in Sicily, lived about 450 B.C. So great was the estimation in which he was held by his fellow-citizens as a physician, a friend of the gods, a predictor of futurity, and a sorcerer, or conjuror of nature, that they are said to have offered him the sovereignty. But being an enemy of tyranny, he declined it, and was the means of delivering the community from the dominion of the aristocracy, and bringing in a democracy. There was a tradition that he threw himself into the crater of Etna, in order that his sudden disappearance might beget a belief in his divine origin; this, however, can only be regarded as a mere fable, like the story told by Lucian, that Etna threw out the sandals of the vain philosopher, and thus destroyed the popular belief in his divinity. The statement of Aristotle is, that he died at the age of 60; later writers extend the period of his life considerably further, but their testimony is not equal in weight to that of Aristotle.

In E., philosophic thought is bound up with poetry and myth even in a higher degree than in Parmenides (q.v.). His general point of view is determined by the influence of the eleatic school upon the physical theories of the Ionic philosophers. He assumed four primitive independent substances—air, water, fire, and earth, which he designates often by the mythical names Zeus, Here, etc. These four *elements*, as they were called, kept their place till modern chemistry dislodged them. Along with material elements, he affirmed the existence of two moving and operating powers, love and hate, or friendship and strife, the first as the uniting principle, the second as the separating. The contrast between matter and power, or force, is thus brought out more strongly by E. than by previous philosophers. The origin of the world, or cosmos, he conceived in this way: In the beginning, the elements were held in a sort of blended unity, or *sphere*, by the attractive force of love; when hate, previously exterior, penetrated as a repelling and separating principle. In this process of separation, which gives rise to the individual objects of nature, he seems to have assumed a series of stages, a gradual development of the perfect out of the imperfect, and a periodical return of things to the elemental state, in order to be again separated, and a new world of phenomena formed. From the fragments that we possess of his didactic poem, it is not quite clear in how far he considered fire as the substratum of strife, and water as the substratum of love, and ascribed various creations to the predominance of one or the other of these principles. Of his opinions on special phenomena, may be mentioned his

doctrine of emanations, which proceeding from one thing enter into corresponding openings in other things. By this assumption in connection with the maxim, that like is known only by like, he thought to explain the nature of perception by the senses. He attempted to give a moral application to the old doctrine of the transmigration of souls, his views of which resembled those of Pythagoras. The fragments of E. have been edited by Sturz (2 vols., Leip. 1805), Karsten (Amst. 1838), and Stein (Bonn, 1852).

EMPEROR (Lat. *imperator*). The original signification of this, which in the modern world has become the highest title of sovereignty, can be understood only when it is taken in conjunction with *imperium*, which in the Roman political system had a peculiar and somewhat technical meaning. The *imperium* of a magistrate, be he king or consul, was the power which he possessed of bringing physical force into operation for the fulfillment of his behests. This power was conferred by a *lex curiata*, and it required this authorization to entitle a consul to act as the commander of an army. In the case of the kings also, the *imperium* was not implied in their election, but was conferred separately, by a separate act of the national will. "On the death of king Pompilius," says Cicero, "the *populus* in the *comitia curiata* elected Tullus Hostilius king, upon the rogation of an *interrex*; and the king, following the example of Pompilius, took the votes of the *populus*, according to their *curie*, on the question of his *imperium*."—*Republic*, ii. 17. Now, it was in virtue of this *imperium* that the title *imperator* was given to its possessor. Far from being an emperor in the modern sense, he might be a consul or a pro-consul; and there were, in fact, many *imperatores*, even after the title had been assumed as a prenominal by Julius Cæsar. It was this assumption which gradually gave to the title its modern signification. In republican times, it had followed the name, and indicated simply that its possessor was an *imperator*, or one possessed of the *imperium*; now it preceded it, and signified that he who arrogated it to himself was *the* emperor. In this form it appears on the coins of the successors of Julius. After the times of the Antonines, the title grew into use as expressing the possessor of the sovereignty of the Roman world, in which sense *princeps* also was frequently employed. In the introduction to the *Institutes*, Justinian uses both, in speaking of himself, in the same paragraph. From the emperors of the west, the title passed to Charlemagne, the founder of the German empire. When the Carlovingian family expired in the German branch, the imperial crown became elective, and continued to be so till it ceased—Francis II., who in 1804 had declared himself hereditary emperor of Austria, having laid it down in 1806. In addition to the emperor of Austria, there are now in Europe the emperor of Russia and emperor of Germany, the latter of whom, was, on Jan. 18, 1871, proclaimed under this title within the hall of mirrors, in the palace of the French kings at Versailles, in the presence of the German princes, and the standards of the German army which was beleaguering Paris. In 1876 the queen of England assumed the title of empress of India, in addition to those which she bore previously. See **EMPIRE**.

EMPEROR MOTH, *Saturnia pavonia minor*, a moth of the same family (*bombycidae*) with the silk-worm moth. The E. M. is the largest British lepidopterous insect. Its expanse of wings is about 3½ inches. Each wing is ornamented with a large eye-like glassy and transparent spot. The peacock moth (*S. pavonia major*) is the largest European species, and attains an expanse of 5 in. across the wings. The cocoons of the E. M. are remarkable for being formed internally of stiff convergent elastic threads, which readily permit the escape of the insect, but prevent the entrance of intruders. The cocoons of this genus of moths are invested with silk, which in China and India is collected for use. See **SILK** AND **SILK-WORM**.

EMPETRA'CEÆ. See **CROWBERRY**.

EMPHASIS. See **ACCENT**.

EMPHYSE'MA, an unnatural distension of a part with air. E. of the cellular texture often takes place in the neighborhood of wounds of the air-passages in the lungs, and is the consequence of an escape of air from these parts. E. of the lungs is the consequence either of distension or of rupture of the air-vesicles, especially on the surface. It is rarely that E. is produced otherwise than mechanically; but collections of fluid in a state of decomposition sometimes give out gases, which penetrate and distend the textures with which they are in contact.

EMPHYTEU'SIS (Gr. an implanting), in the Roman law, a perpetual right in a piece of land, for which a yearly sum was paid to the superior or original proprietor. The E. much resembled our feudal holdings, so much so, indeed, that Craig and other Scotch writers apply the term to them. The sum paid to the superior was called the *canon emphyteuticus*. The tenant handed down the right to his heirs, and was entitled to sell, but only on condition of giving the first offer to the dominus. The consent of the lord, however, was not necessary to entitle him to impignorate the *emphyteuta* for his debt. Justinian put the E. and the *ager vectigalis* on the same footing. The latter is the term applied to lands leased by the Roman state, by towns, ecclesiastical corporations, and by the vestal virgins. There were several ways in which the right of E. might cease. If the tenant died without heirs, it reverted to the dominus. He might also lose his right by injuring the property, by non-payment of his rent or public burdens, or by

alienation without notice to the dominus. It was, of course, also in his power to renounce it.

EMPIRE (see **EMPEROR**) denotes the territory and people whose sovereign bears the title of emperor or empress; a title which, since the time of Julius Cæsar, implies the possession of monarchical power in its highest form. During the middle ages and until a comparatively recent period the "Empire" in its strictest sense meant the "holy Roman empire" founded by Cæsar and Augustus, the last remnant of which was lost in 1806, when Francis II. of Hapsburg, archduke of Austria and king of Hungary and Bohemia, resigned his inherited imperial title and assumed that of emperor of Austria alone. The Roman empire, from A.D. 395, was divided into two parts, one of which was ruled from Rome, the other from Constantinople. In theory, however, the two were held to be parts of one empire, divided only for greater convenience of administration. This was fiction rather than fact, for the two parts were in perpetual conflict. An attempt to restore the unity of the two under Charlemagne, who in 800 was crowned emperor at Rome by pope Leo III., proved abortive. Two hostile lines of emperors arose, each claiming to be the one true succession from Augustus and Constantine. The imperial title fell low, until it was revived in the w. in 963 by Otto the great, from whose time there was an unbroken succession of German kings, who assumed the rank and right of emperors and were acknowledged as such by the church. Their power, however, did not extend beyond Germany and northern Italy, and it was hampered by many restrictions, which were aggravated as time went on, until after the peace of Westphalia, in 1648, when the empire was reduced to a mere federation of principalities and the imperial title became little better than a farce. The eastern empire was overthrown in 1453, when Constantinople was taken by the Turks. The empires now existing are those of Austria, Russia, Germany, Turkey, China, and Japan. The queen of England bears the title of empress of India.

EMPIRE STATE. See **STATES**, **POPULAR NAMES OF**.

EMPIRIC (Gr. *empeirikos*, an experimentalist, or searcher after facts in nature, from *peiraō*, I try). It is difficult to say at what period, or in what manner, this word began to degenerate from its original meaning. Probably the idea was, that empiricism, or experimental science, excluded, because it did not require, the reasoning faculties for its cultivation; and, therefore, the profession of empiricism came to be synonymous with vulgar ignorance. The empirics were a regular sect of ancient physicians in the time of Celsus and Galen, who give us some insight into their modes of thought and practice. They laid great stress on the unprejudiced observation of nature; and thought that, by a careful collection of observed facts forming a history, the coincidence of many observations would lead to unalterable prescriptions for certain cases. The later adherents of the school excluded all theoretical study, even that of anatomy, and were guided solely by tradition and their individual experience. By an E. in medicine is now understood a man who, from want of theoretic knowledge, prescribes remedies by guess according to the name of the disease or to individual symptoms, without thinking of the constitution of the patient or other modifying circumstances. What are called *specifics* are administered on this principle, or want of principle.

EMPIRICAL FORMULA, in chemistry, is the mode of expressing the constituents of a compound in symbols, where the total quantity of each element is written down without reference to any particular order or state of combination. Thus, alcohol consists of 2 equivalents of carbon, 6 of hydrogen, and 1 of oxygen; and its E. F. is C_2H_6O . When regarded, however, as a member of a family group, the constituents are arranged in a more systematic manner, as in $CH_3 \cdot CH_2 \cdot OH$, representing the theoretical constitution of alcohol, which, to speak with strictness, is the hydrate of ethyl. Again, the rational formula of Epsom salts, which is $MgSO_4 + 7H_2O$, represents it theoretically as a hydrated sulphate of magnesia; while the E. F. $MgH_{14}SO_{11}$ merely tells us that it consists of 1 equivalent of magnesium, 1 of sulphur, 14 equivalents of hydrogen, and 11 of oxygen.

EMPIRICAL LAWS are such as express relationships, which may be merely accidental, observed to subsist among phenomena, but which do not suggest or imply the explanation or cause of the production of the phenomena. They are usually tentative, and form stages in the progress of discovery of causal laws. Bode's law of the distances of the planets from the sun is an example of an empirical law.

EMPLOYERS' LIABILITY. See **FACTORY ACTS**, and **MASTER AND SERVANT**.

EMPOLI, a t. of Italy, is situated in the province of Florence, in a remarkably beautiful and fertile district on the left bank of the Arno, 16 m. w.s.w. of Florence. It is surrounded by walls flanked with towers. The most interesting building is the Collegiate church, built in 1093.

EMPORIA, city and co. seat of Lyon co., Kan.; between Cottonwood and Neosho rivers; on the Missouri, Kansas and Texas, and the Atchison, Topeka and Santa Fé railroads; 61 m. s.w. of Topeka. It contains churches, national banks, flour-mills and manufactories; a State Normal School, College of Emporia, excellent schools, business college, conservatory of music, gas and electric lights, water-works owned by the city, etc. The surrounding country is a fertile prairie. Pop. '90, 7551.

EMPORIUM (Gr. *emporion*, trading-place). The word is derived from *emporos*, which signified in Homer's time a person who sailed in a ship belonging to another, but latterly meant a wholesale merchant, as opposed to a retailer, who was called *kapēlos*. An *E.* thus came to be applied to the receptacles in which wholesale merchants stowed their goods in seaports and elsewhere, and thus corresponded to our warehouses, as opposed to a shop.

EMPTION. See **SALE OF GOODS**.

EMPYEMA (Gr.), an internal suppuration, a word now applied exclusively to a collection of pus in the pleura, causing pressure of the lung, and often attended by hectic fever. See **PLEURISY**.

EMPYREU MA (Gr. *empyreuo*, I kindle), the burned smell and acrid taste which result when vegetable or animal substances are decomposed by a strong heat. The cause of the smell and taste resides in an oil called *empyreumatic*, which does not exist naturally in the substance, but is formed by its decomposition.

EMS, a river in the n.w. of Germany, rises in Westphalia, at the southern base of the Teutoburger Wald, and flowing first in a north-western, and then through the Hanoverian territories in a northern direction, empties itself into Dollart bay, an estuary of the German ocean, after a course of 200 miles. Its chief affluents are the Aa, the Haase, and the Leda. It is navigable for vessels of 100 tons as high as Pappenburg, which is 25 m. up the river from Dollart bay. The *E.* drains a basin of about 5,000 sq. m. in extent. In 1818 it was connected by canal with the Lippe, and with the Jade.

EMS, usually called the *Baths of Ems*, to distinguish it from other places of the same name, a bathing-place known to the Romans, and celebrated in Germany as early as the 14th century. It is situated about 4 m. from Coblenz, near the most picturesque parts of the Rhine, in a beautiful valley in the province of Hessen-Nassau, traversed by the navigable river Lahn, and surrounded by wooded hills. Pop. '90, 5472. Its warm mineral springs belong to the class containing soda; the only essential difference between the numerous springs is in the temperature varying from 24° to 46° Reaumur, and in the greater or lesser amount of carbonic acid gas contained in them. The bathing establishments are comfortably and luxuriously fitted up, as are also the hotels and private lodging-houses.

EMSER, HIERONYMUS, 1477-1527; a Roman Catholic theologian of Germany, distinguished as an opponent of Martin Luther. His most notable exploit was the publishing of a translation of the New Testament which he claimed as his own work, though it was really a reprint of Luther's translation with some slight alterations.

EMU (*Dromaius*—or *dromecius*—*Novæ Hollandiæ*), a very large bird, one of the *struthionidæ* or *brevipennes*, a native of Australia, and widely diffused over the southern parts of that continent and the adjacent islands. It is by some ornithologists referred to the same genus with the cassowary, but the differences are very considerable; the bill being horizontally depressed, whilst that of the cassowary is laterally compressed, the head feathered, and destitute of bony crest; the throat is nearly naked, and has no pendent wattles; the feet are three-toed as in the cassowary, but the claws are nearly of equal length. The name *E.* or *emue* was given by the older voyagers and naturalists to the cassowary, but is now the invariable designation of the Australian bird. The *E.* is even taller than the cassowary, which it resembles in the general character of its plumage. Its wings are mere rudiments hidden beneath the feathers of the body. Its color is a dull brown, mottled with dingy gray; the young are striped with black. When assailed, it strikes backwards and obliquely with its feet, like the cassowary, and it is so powerful that a stroke of its foot is said to be sufficient to break a man's leg. Dogs employed in hunting it are often injured by its kicks, but well-trained dogs run in before it, and spring at its neck. It cannot fly, but runs very fleetly. It is timid and peaceful, and trusts altogether to its speed for safety, unless hard pressed. In a wild state, it sometimes occurs in small flocks; but it has now become rare in and around all the settled parts of Australia. The extinction of the species may, however, perhaps be prevented by its being preserved in a state of domestication; as its flesh is excellent, and it is very easily domesticated, and breeds readily in that state. It has frequently bred in Britain. The eggs are six or seven in number, dark green; the male performs the principal part of the incubation. The eggs are highly esteemed as food. The skin of the *E.* contains much oil—six or seven quarts are obtained from a single bird, and on this account it has been much hunted in Australia. The food of the *E.* consists chiefly of roots, fruits, and herbage. Its only note is a drumming sound, which it frequently emits.

EMULSINE, or **SYNAPTASE**, is a peculiar ferment present in the bitter and sweet almond, and which forms a constituent of all almond emulsions. When bitter almonds are bruised, and water added, the *E.* acts as a ferment on the amygdalin, and decomposes the latter into volatile oil of bitter almonds, prussic acid, grape-sugar, formic acid, and water (see **ALMONDS**, **VOLATILE OIL**, or **ESSENTIAL OIL OF**). The vegetable albumen of almonds is almost entirely composed of *E.*; which, when separated, is a white substance, soluble in water, and is distinguished by its remarkable power of

causing the fermentation of amygdalin. It consists of carbon, hydrogen, nitrogen, and oxygen.

EMULSION is the term applied to those preparations in pharmacy obtained by triturating certain substances with water, and where the product is a milky white opaque mixture of a gummy consistence, and composed more or less of oily particles floating in mechanical suspension in the mucilaginous liquid. The *true* and *oily* emulsions are those containing true oil, as the E. of bitter almonds, obtained by bruising the latter in a mortar with water; and the *false*, or *not oily*, where no true oil is suspended, as where camphor, balsams, or resins are rubbed up with yolk of egg, mucilage, or dilute spirit of wine.

EMYDÆ, a genus of marsh tortoises, from which the whole family of marsh tortoises is sometimes called *emydæ*. The chelonians of this family are numerous, and widely diffused throughout the warmer parts of the world. They differ more in their habits than in their appearance and structural characters from land tortoises. Their carapace, however, is more flattened, and their feet are more expanded and webbed, so that they swim with great facility. They feed chiefly on animal food, as insects and mollusks, aquatic reptiles, and fishes, some of them even preying upon birds and mammalia which come within their reach. Two or three species of *emydæ* are natives of the s. of Europe; but two species are particularly abundant in North America, the painted tortoise (*emys picta*), and the alligator tortoise (*emysaura serpentina*). The flesh of some, as *cistudo Europæa*, is esteemed for food. This small species, about 10 in. long, an inhabitant of lakes, marshes, and muddy places in the s. and e. of Europe, is sometimes kept in ponds, and fattened for the table on lettuce-leaves, bread, etc.

ENALIOSAURIANS (Gr. marine lizard), an order of fossil marine saurians commencing in the carboniferous, and ending in the cretaceous periods, being most abundant in the jurassic. They have biconcave vertebræ, like those of fishes, teeth like those of crocodiles, a lizard body, and the paddles of cetaceans instead of true feet, an apparently incompatible combination. Some had long snake-like necks, and most of them were of great size, and must have been exceedingly voracious. They comprise two groups, the ichthyosaurians and simosaurians. The ichthyosaurians belong to the jurassic and cretaceous formations, while the simosaurians have been found only in the triassic. The two principal genera of the ichthyosaurians are the ichthyosaurus and the plesiosaurus, and they are the most generally known. See **ICHTHYOSAURUS** and **PLESIOSAURUS**.

ENAMEL (Fr. *émail*, originally *esmail*, from the same root as *smelt*), the name given to vitrified substances of various composition applied to the surface of metals. Enameling is practiced (1) for purposes of utility, as in making the dial-plates of watches and clocks, coating the insides of culinary vessels, etc., when it may be considered as belonging to the useful arts; and also (2) for producing objects of ornament and beauty—artistic designs, figures, portraits, etc., when it belongs to the fine arts. Both the composition of enamels and the processes of applying them are intricate subjects, besides being in many cases kept secret by the inventors; and we can only afford space for the most general indications of their nature. The basis of all enamels is an easily fusible colorless silicate or glass, to which the desired color and the desired degree of opacity are imparted by mixtures of metallic oxides. The molten mass, after cooling, is reduced to a fine powder, and washed, and the moist paste is then usually spread with a spatula upon the surface of the metal; the whole is then exposed in a surface (*fired*, as it is called) till the E. is melted, when it adheres firmly to the metal. The metal most commonly used as a ground for E. is copper; but for the finest kinds of enamel-work gold and silver are also used.

Artistic or Ornamental Enameling.—This art is of great antiquity: it is proved by the remains found in Egypt to have been practiced there; from the Egyptians it passed to the Greeks, and it was extensively employed in decoration by the Romans; in the reign of Augustus, the Roman architects began to make use of colored glass in their mosaic decorations; various Roman antiquities, ornamented with E., have been dug up in Britain, and it was adopted there by the Saxons and Normans. A jewel found at Athelney, in Somersetshire, and now preserved in the Ashmolean museum at Oxford, is proved by the inscription on it to have been made by order of Alfred; and there are various figures with draperies partly composed of colored E. on the sides of the gold cup given by king John to the corporation of Lynn, in Norfolk.

Enameling has been practiced from a remote period in the east, Persia, India, and China, under a separate and distinct development; but there is nothing from which it can be inferred that the various methods were in use earlier than in Europe. As a decoration, enameling was more popular, and attained to greater perfection in the middle ages than in classic times. It was extensively practiced at Byzantium from the 4th until the 11th c., and afterwards in Italy in the Rhenish provinces, and at Limoges in the s. of France, where it was successfully followed out till a comparatively late period, in several different styles. The Byzantine and other early styles of enamel-work down to the 17th c. were generally employed in ornamenting objects connected with the service of the church, such as reliquaries, pyxes, church-candlesticks, crosiers, portable altars, the frontals of altars, etc.; the art was also greatly used in ornamenting jewelry, and

vessels made for use or display in the mansions of the rich, such as salt-cellars, coffers, ewers, plateaux, candlesticks, etc. After this period the art declined, until a new phase of it was invented in France, in which E. is used as a ground, and the figures are painted with vitrified colors on the surface of it. This is enamel-painting properly so-called, the earlier styles being more of the nature of mosaics.

Distinguished with reference to the manner of execution, enamel-work may be divided into four kinds: 1. *Cloisonée*, or inclosed, the method of the Byzantine school, in which the design is formed in a kind of metal case, generally gold or copper, and the several colors are separated by very delicate filagree gold bands, to prevent them running into each other. 2. *Champ Levé*, practiced by the early Limoges school. In this process the ornamental design, or the figures that were to be filled in with color, were cut in the metal (generally copper) to some depth; and wherever two colors met, a thin partition of the metal was left, to prevent the colors running into each other by fusion when fired. 3. Translucent E., which had its origin, and was brought to great perfection in Italy, was composed of transparent E. of every variety of color, laid in thin coatings over the design, which was incised on the metal, generally silver, the figure or figures being slightly raised in low relief, and marked with the graver, so as to allow the drawing of the contours to be seen through the ground, instead of being formed by the coarse lines of the copper, as in the early Limoges enamels. 4. Surface-painted enamels, which may be divided into two stages. The first stage, which is known as the *late Limoge* style, sprang up under Francis I. of France (1515-47). In this the practice was to cover the metal plate with a coating of dark E. for shadows, and to paint on this with white, sometimes set off with gold hatchings, sometimes having the hands and other parts of the figures completely colored. The designs were generally taken from well-known paintings or engravings of the period; and the style of the designs was strongly influenced by that of the Italian artists employed by Francis I. This style soon degenerated, and gave place to the latest or *miniature* style, which was invented before the middle of the 16th c. by Jean Toutin, a goldsmith at Chateaudun, and carried to the highest perfection by Jean Petitot, a miniature-painter, who was born at Geneva, 1607, and afterwards resided long in England, and then in Paris. In this the plate is covered with a white opaque E., and the colors are laid on this with a hair-pencil, and fixed by firing. The paints are prepared by grinding up colored enamels with some kind of liquid, and when fused by the heat, they become incorporated with the E. of the ground. The earlier enamellers of this school occupied themselves with miniatures, snuff-boxes, and other trinkets, till the period of the French revolution, when the art fell into disuse. It was, however, revived in England early in this century; and copies of portraits and pictures on a much larger scale than the French miniatures were executed with much success by the late H. Bone, R.A., and the late Charles Muss. Works of this description possess the obvious advantage of durability; but those various qualities of texture, and the delicacy of color for which good works in oil or water-color are prized, cannot be attained in E. copies; and it is to be regretted that greater efforts are not made to turn enameling to account in the way of ornamentation, for which it is so admirably fitted, rather than in attempts at imitating works classed strictly as within the bounds of fine art, and to put in practice the older styles of enameling, particularly those denominated *champ levé* and transparent enameling.

Enameled-ware.—The liability of iron to oxidation by heat or moisture, and to corrosion even by the weakest acids, has led to many attempts to coat it with a protecting surface. Ordinary tin plate is the oldest and most familiar example of a partially successful method. Since the beginning of the present century, many attempts have been made to cover iron with a vitreous surface, and several patents have been taken for such methods of enameling. The chief difficulty in applying enamels to iron arises from the tendency of the metal to oxidize before it reaches the temperature at which the E. fuses, and to become brittle from the oxide combining with the silica of the enamel. This action being superficial, the mischief is the greater in proportion to the thinness of the iron. Therefore it is much easier to E. thick cast-iron vessels than thin vessels made of sheet-iron. A glass may be made by combining either silicic acid or boracic acid with a base; the latter fuses at a lower temperature than the former, but the glass is much dearer and not so durable as the silica glass. The enamels used for coating iron consist of a mixture of silica and borax, with various basic substances, such as soda, oxide of tin, alumina, oxide of lead, etc.

The best E. for such purposes with which we are acquainted, is that patented by C. H. Paris, and applied by Messrs. Griffiths and Browett of Birmingham. It consists of 130 parts of flint-glass powdered, 20½ parts of carbonate of soda, 12 of boracic acid. These are fused together to form a glass, then reduced to a very fine powder; the article to which they are to be applied is carefully cleaned with acid, then brushed over with gum water, and the powder dusted upon it. The gum water is merely to cause adhesion. This coating is then carefully dried, and heated just to the point at which the powdered glass will fuse, and by running together, coat the surface. The E. is generally put on in two separate layers or coatings, the first being dull gray, and the second or outer one of some brighter color. For sheet-iron hollow-ware, the latter is usually white, upon which a pattern is often printed with transfer paper by the process in use for earthenware (see POTTERY). These light enameled iron vessels, from their being practically

indestructible (except when used for cooking), are made in large numbers for use on board ships, and for colonial markets. A great variety of articles, many of them beautifully decorated in colors, such as grate-fronts, clock-dials, panels of different kinds, tablets, and name-plates, are now executed in enameled iron at a comparatively moderate cost. It is also applied to corrugated roofing. See HOLLOW-WARE.

ENAMEL OF TEETH. See TEETH.

ENARËA, a country of Africa, s. of Abyssinia, is situated within lat. 7° to 9° n., and long. 36° to 38° e., but its limits have not yet been definitely ascertained. It is inhabited by a portion of the Gallas tribes, who, owing to the continued communication which they keep up with Abyssinia, and also to the residence of many Mohammedan merchants among them, are much more civilized than the Gallas usually are. Their government is a hereditary and absolute monarchy. The principal rivers of E. are the Gibbe and the Dodesa. The capital is Saka.

ENARTHROSIS is the term used by anatomical writers to express the kind of joint (q.v.) which admits of the most extensive range of motion. From this mode of connection and the form of the bones in this articulation, it is commonly called the ball-and-socket joint. It occurs in the hip and shoulder joints.

ENCÆNIA, dedication festivals held by the early Christian church on the occasion of consecrating a heathen temple to Christian use, and afterwards held on the anniversaries of such occasions. At first they were very simple but about the beginning of the seventh century they became more elaborate, and included dramatic presentations, singing and dancing, until their proceedings met with disapproval from the Council of Chalons. In later times, the festivals held at Oxford and Cambridge in honor of their founders were called *Encænias*.

ENCAMPMENT. See CAMP.

ENCAUSTIC PAINTING (Gr. *encaustikē*, infired, or fixed by fire), a manner of painting practiced by the ancients. As the name implied that fire was used in the execution, some have been led to suppose that E. P. was the same as enamel painting; but notices by Pliny and other writers show clearly that it was a species of painting in which the chief ingredient used for uniting and fixing the colors was wax dissolved by heat. Various attempts have been made in modern times to revive it. About the middle of last century, count Caylus and M. Bachelier, and in 1792, Miss Greenland, made various experiments with this view. The count laid the result of his experiments before the academies of painting and of sciences in Paris; and the ingenious lady was rewarded with a gold pallet by the society for the encouragement of arts in London; but the success of these efforts seems to have been but temporary. E. P. was, however, some years ago again taken up in Germany under the patronage of the late king of Bavaria, who had a number of important works executed in this way. The colors are ground, and laid on with a vehicle composed principally of wax. Miss Greenland dissolved gum-arabic in water, afterwards adding gum-mastic, which was dissolved by stirring and boiling, and when the mixture had reached the boiling-point, she put in the wax. After painting the picture, she passed a thin coating of melted wax over it with a hard brush, and then drew over the surface an iron—for ironing linen—moderately heated. After the picture cooled, it was rubbed with a fine linen cloth. The German method is somewhat similar, but some other ingredients are used; among these, potash with the wax; and in place of an iron being passed over the surface, the wax is brought to the surface by a vessel containing fire being held at a little distance from the picture. E. P. is not likely to come into general use, for neither in imparting brilliancy to the colors, facility for execution, nor durability, is it to be compared with oil-painting.

ENCAUSTIC TILES, ornamental tiles made of earthenware, and now extensively used for paving churches, halls, conservatories, etc. Strictly speaking, the name applies only to tiles with a pattern produced by layers of different-colored clays; but we may also include those made of a single color where two or more kinds go to form a pattern. Of course a mosaic can thus be formed with tiles of various forms as well as colors. Tiles of one color are made of dried slip—that is, the powder of carefully mixed and prepared clay. These “dry tiles” are made by placing the colored clay powder in strong steel molds, and subjecting it to a pressure of several hundred tons, by means of a plunger fitting accurately into the mold. A depth of 3 in. of powder is compressed into a tile of 1 in. in thickness. It is then removed, heated in a hot chamber, fired, and glazed if required.

The figured tiles are made in a different manner. The clay is worked in a moist state, but very stiff, first into square blocks. These are cut into square slices or slabs by passing a wire through them; upon this is put a facing of fine clay of the color of the ground of the pattern—another layer, of a different quality of clay, is sometimes added to the bottom, to prevent warping. It is then placed in a mold, with a plaster-of-Paris slab forming the top, on the under surface of which is the pattern in relief. This slab is pressed down, and thus forms a deep impression of the pattern which is to be produced in another color. The clay of the requisite color to form the pattern is now poured, in a semi-fluid state, into this depression, and allowed to flow over the whole face of the tile; then it is set aside until dry enough to have its surface scraped and smoothed on a whirling table. By this means the superfluous clay is removed, and the pattern is

brought out clear and well-defined, the two colors of clay forming one smooth flat surface. The tile is then dried and fired.

By Malkin's patent process, inlaid as well as plain tiles are now wholly made of dried slip. The pattern is produced by the use of brass plates one eighth of an inch thick, a separate one being used for each color. Thus, if it consist of an ornament in red and white on a blue ground, one plate is perforated so as to enable the red portion of the clay powder to be filled in, another is cut for the white portion, and a third for the blue ground. When all are filled up, the tile is pressed in a screw-press and fired.

Tiles of this kind were used for paving churches in England and on the continent from the 12th to the 15th c., after which they fell into disuse. The modern manufacture is therefore nothing more than a revival, with some improvements, of an ancient art.

ENCEINTE (Fr.), in fortification, denotes generally the whole area of a fortified place. Properly, however, it means a cincture or girdle, and in this sense the *enceinte* signifies the principal wall or rampart encircling the place, comprising the curtain and bastions, and having the main ditch immediately outside it.

ENCEPHALOCELE (derived from the Gr. *encephalon*, the brain and *cele*, a tumor), is the term applied to a tumor projecting through the skull, in one of the parts where the bones are incomplete in infancy, and consisting of a protusion of the membranes of the brain, containing a portion of brain itself. The most common situation of such tumors is in the middle line and at the back of the head. Surgical interference is scarcely ever justifiable, and all that can usually be done is to give uniform support to the tumor, and to defend it from injury.

ENCHON DROMA is the term employed in pathological anatomy to signify an abnormal cartilaginous growth. These growths most commonly occur in connection with the bones, and they are not unfrequent in some of the glandular structures. See **TUMORS**.

ENCHORIAL CHARACTERS. See **HIEROGLYPHICS**.

ENCINA, OR ENZINA, JUAN DEL, 1469-1534; the father of the Spanish drama, educated at Salamanca. About the close of the century he began to exhibit dramas of his own construction, in which he sometimes played low comedy parts. Early in the 15th c. he went to Rome and joined the priesthood. He visited Jerusalem, and published an account of his journey. His dramatic works mark the transition from the purely religious to the secular stage.

ENCINAL, a co. in s. Texas; unorganized and attached to Webb co. for judicial purposes; crossed in n.e. corner by Nueces river; surface uneven; land uncultivated, and used for pasturage; 1700 sq.m. Pop. '90, 1022.

ENCKE, JOH. FRANZ, the well-known astronomer, was b. Sept. 23, 1791, at Hamburg, where his father was a clergyman. After studying at Göttingen, he served, during the campaign of 1813-14, in the artillery of the Hanseatic legion, and in 1815, in the Prussian army, as lieut. of artillery. On the establishment of peace, he left the service, and became assistant, and afterwards principal astronomer in the observatory of Seeberg, near Gotha. In 1825, chiefly at the instigation of Bessel, he was called to Berlin as successor to Tralles, in the secretaryship of the academy of sciences, and as director of the observatory. While at Gotha, the astronomical prize offered by Cotta was awarded to E. by the judges Gauss and Olbers, for his determination of the orbit of the comet of 1680. This led him to solve another problem, which had been proposed along with the other—viz., the distance of the sun. The solution, by means of the two transits of Venus in 1761 and 1769, is published in two separate tracts (*Die Entfernung der Sonne*, Gotha, 1822-24). In 1819, he proved that the comet discovered by Pons, Nov. 26, 1818, revolved in the hitherto incredibly short period of about 1200 days, and had been already observed in 1786, 1795, and 1805. It has since gone by the name of E.'s comet, and has appeared regularly; the period of its recurrence being 3.29 years, or about $3\frac{3}{10}$ years. See **COMET**. E.'s researches on this subject are contained in the *Transactions of the Berlin Academy*. In 1830, he undertook to edit the *Berlin Astronomical Almanac*, in which he published a number of astronomical treatises. Three volumes have appeared of *Astronomical Observations at the Berlin Observatory*, begun in 1855. He died 26th Aug., 1865.

ENCORE ("Again"), a French expression, generally used in England by the audience of a theater or concert-room, when requesting the repetition of the performance of a piece of music. It is not used by the French themselves, who, in similar circumstances, exclaim *bis* (twice).

ENCRATITES, the name of early ascetics in the Christian church, who forbade marriage, the eating of the flesh of animals, and the use of wine, going so far as to substitute water for wine in the eucharist.

ENCRI'NAL, OR ENCRIN'ITAL, LIMESTONE, a name given to some carboniferous limestones, from the great abundance in them of the calcareous skeletons of encrinites (q.v.), whole masses of the rock being almost entirely composed of them. There are large beds in the Hamilton and Helderberg groups in New York state.

ENCRINITES, a name applied generally to the fossil crinoidea, a family of echinodermata (q.v.). The popular name, *stone lilies*, is given to the numerous fossil species.

from the resemblance which many of them present when the rays are closed to the lily. Hence also the name *crinoidea*. Crinoids are characterized by having their bodies supported, during the whole or part of their existence, on a longer or shorter jointed calcareous stem. The stem is attached either by the expanded base, or by jointed processes, to the rocky bed of the sea, or perhaps, in some cases, to floating bodies, like barnacles. Occasionally, numerous root-like side-arms are sent out from the base of the stem to strengthen and support it; and in some species, as in the recent *pentacrinus*, the column throughout its length is furnished with axillary side-arms. The stem is round or five-sided; in one genus only is it elliptical. It is composed of a number of joints, perforated in the center, for the passage of a soft portion of the animal, and beautifully sculptured on the articulating surfaces. The body is cup-shaped, and composed of many-sided plates on the under surface, to the center of which the stalk is attached, while the upper surface is covered with a coriaceous skin, protected by many small plates. On this was situated the mouth, which was frequently probosciform, and near it was the anal orifice—the alimentary canal being turned upon itself, as in the bryozoa. The arms spring from the edges of the cup. They are five in number at their origin, but, with few exceptions, speedily divide and subdivide dichotomously. The arms are composed of articulated calcareous joints, similar to those of the stems. Each joint is furnished with two slender-jointed appendages or cirri, of use to the animal in capturing its prey, which consisted of mollusca and other small animals. The number of joints in some species is truly amazing. Dr. Buckland calculated that *pentacrinus briareus* consists of at least 150,000; and “as each joint,” according to Carpenter, “was furnished with at least two bundles of muscular fiber—one for its extension, the other for its contraction—we have 300,000 such in the body of a single *pentacrinus*, an amount of muscular apparatus far exceeding anything that has elsewhere been observed in the animal kingdom.”

The family commenced its existence with the earliest sedimentary deposits. Seventy-three genera have been described, containing upwards of 300 species, two thirds of which are found only in paleozoic rocks. The most ancient E. have nearly all round stems, the few that are five-sided having the articulated surface of the joints simply radiated, and not complexly sculptured as in *pentacrinus*, the type of a division of the order which appears first in the lias. The earlier seas literally swarmed with these animals. “We may judge,” says Dr. Buckland, “of the degree to which the individual crinoids multiplied among the first inhabitants of the sea, from the countless myriads of their petrified remains which fill so many limestone beds of the older formations, and compose vast strata of entrochal marble, extending over large tracts of country in Northern Europe and North America. The substance of this marble is often almost entirely made up of the petrified bones of encrinites.” See CRINOIDEÆ; and illus., MUSCHELKALK PERIOD, Vol. X.

ENCUMBRANCE. See INCUMBRANCES.

ENCYCLICAL LETTERS. (Gr., *encyklius*, “circular,” “periodical,” “general.”) This term denotes in a general sense, circular ecclesiastical letters, whether from a council, bishop or pope. In the early church the letters sent by the member of a council to all the churches, or by a bishop to all the churches of a particular circuit, were so called; but the term is now applied exclusively to letters addressed by the Pope to all the bishops of the Roman Catholic church, which usually contain injunctions, and warnings against dangers which may threaten the church. One of the most recent encyclicals was issued by Pope Leo XIII. in 1888, on the subject of socialism.

ENCYCLOPÆDIA means properly a book or work professing to give information, more or less full, on the whole circle of human knowledge. The name is compounded of two Greek words, *enkyklios*, circular or general; and *paideia*, discipline or instruction. These words were used by the Greeks and Romans to signify the circle of instruction through which every free-born youth had to pass before entering on public life. That circle embraced more particularly grammar, music, geometry, astronomy, and gymnastics, and afterwards became the “seven liberal arts” of the middle ages. The compound name E. appears to have been unknown to the Greeks, and also to the Latin writers of the classic period; and there is no evidence that either Greeks or Romans ever applied the words, single or compounded, to designate a book. The short form *Cyclopædia* has still less classical authority than *encyclopædia*.

Encyclopædias, in the modern sense of the word, are most commonly alphabetical; but sometimes the arrangement is “rational,” i.e., according to the natural relations of the subjects. An alphabetical E. is a dictionary of universal knowledge. Besides this, its proper meaning, of a repertory of universal knowledge, the name E. is often applied—less properly perhaps—to alphabetical works whose scope is limited to a particular branch—works differing in no respect from others which are styled dictionaries, gazetteers, etc. See DICTIONARY. As all works of this kind, which now form a large and increasing section of literature in every language, have in so far a common character with encyclopædias proper, we may give some account of the whole class under the present head.

For the sake of convenience, they may be arranged in three divisions: 1. The earlier works of this kind, having, for the most part, merely an encyclopædic character, i.e., embracing a large range of subjects, without distinctly aiming at universality; 2. Ency-

clopædias proper, which treat of the whole circle of human knowledge; 3. Books professedly confined to a definite department of knowledge, whether under the name of E., dictionary, gazetteer, or other title. As books of this class profess to touch on every important point that comes within their scope, they may be considered as encyclopædic in a limited sense. In the following sketch, the distinction between the first and second of those classes, which is of a somewhat indeterminate kind, is not strictly adhered to when it would interfere with the chronological sequence.

1. The earliest work of an encyclopædic character is generally ascribed to Speusippus, a disciple of Plato. The great collections of Varro (*Rerum Humanarum et Divinarum Antiquitates* and *Disciplinarum libri ix.*), of the elder Pliny (*Historia Naturalis*), of Stobæus, of Suidas, of Isidorus (the *Origines*), and of Capella, belong to the same class, but they exhibit no plan, and are only confused accumulations of the then known arts and sciences. Vincent of Beauvais (1264) surpassed them all. He gathered together with wonderful diligence the entire knowledge of the middle ages in three comprehensive works, *Speculum Historiale*, *Speculum Naturale*, and *Speculum Doctrinale*, to which soon after an unknown hand added a *Speculum Morale*. But these, as well as the other similar compilations which appeared in the later mediæval period under the title of *Summa*, or *Speculum* (mirror), are marked throughout by a lack of philosophic spirit. Perhaps the nearest approach to the modern E. by an ancient writer, dates two centuries earlier than the time of Beauvais. In the 10th c., flourished Alfarabius, the ornament of the school of Bagdad, who wrote an encyclopædic collection of knowledge, remarkable for its grasp and completeness, and which still lies in MS. in the Escorial of Spain. Among the earliest and most noted of the modern encyclopædias was that of Johann Heinrich Alsted, or Alstedius, which appeared in Germany in two volumes in 1630. It consisted of 35 books in all, of which the first four contained an explanation of the nature of the rest. Then followed six on philology, ten on speculative and four on practical philosophy; three on theology, jurisprudence, and medicine; three on the mechanical arts; and five on history, chronology, and miscellaneous topics. Two important French works belong to this century—the one is Louis Moreri's *Grand Dictionnaire Historique et Critique*, of which the first edition appeared at Paris in 1673, and the last in 1759; the other, Peter Bayle's famous *Dictionnaire Historique et Critique*, published at Rotterdam, in 4 vols., 1697. The first encyclopædic dictionary, so far as known, appeared in Germany as the *Lexicon Universale* of Hoffmann (2 vols., Basel) in 1677. Some time after there appeared in France, Thomas Corneille's *Dictionnaire des Arts et des Sciences*, 2 vols. (Paris, 1694). Dictionaries limited to the explanation of technical terms had long been common throughout Europe; but previous to Hoffmann's work, no attempt had been made to bring the whole body of science and art under the lexicographic form. A highly successful attempt identical in kind, and attributable in idea, it may be, to the German work just alluded to, was the *Lexicon Technicum* of Dr. Harris, 2 vols. folio (London, 1710), which may fairly be regarded as the parent of all the dictionaries of arts and sciences that have since appeared in England. The *Cyclopædia* of Ephraim Chambers, published in 1728, in two very large folio volumes, presents the next marked advance in the construction of encyclopædical dictionaries. This one was brought out with considerable claims to originality of arrangement. The author endeavored to communicate to his alphabetical materials something of the interest of a "continuous discourse," by an elaborate system of cross references. Another peculiarity of this cyclopædia was that its author, in the details of mathematical and physical science, gave only conclusions and not processes of demonstration. It was long a very popular work. The largest and most comprehensive of the successors to Hoffmann's book in Germany, was Zedler's *Universal Lexicon*, 64 vols. (Leip. 1732-50). In point of comprehensiveness, this work should be classed with the encyclopædias proper, there being almost nothing then known that may not be found in it. Perhaps the strongest impulse, if not in all respects the best, communicated by this successful attempt of Ephraim Chambers, was given to the French mind through D'Alembert and Diderot. Their *Encyclopédie* was really, though not professedly, founded upon E. Chambers's book, which an Englishman named Mills had translated between 1743 and 1745, though the French version of it never was published. The great French *Encyclopédie* was written by various authors of high literary and philosophical attainments, but of whom nearly all were tainted too much with the most impracticable revolutionary ideas, besides holding for the most part extremely skeptical opinions. The *Encyclopédistes* excluded both biography and history from its scope, yet infused into it more originality, depth, and ability, than ever had appeared before within the boards of an encyclopædical dictionary. It appeared at Paris in 28 vols. between the years 1751-72, and was followed by a supplement in 5 vols. (Amst. 1776-77), and an analytical index in 2 vols. (Paris, 1780). The work was everywhere received with the greatest enthusiasm, and it secured a place in the literary history of the nation for the editors and principal writers, who are ordinarily known as the *Encyclopédistes* of France. They were D'Alembert and Diderot the editors, Rousseau, Grimm, Dumarsais, Voltaire, baron d'Holbach, and Jancourt. [See La Porte's *Esprit de l'Encyclopédie* (Paris, 1768); and Voltaire's *Questions sur l'Encyclopédie* (Paris, 1770).] D'Alembert's celebrated preliminary discourse was garbled in various pretentious works of this class published for the most part in England; such were Barrow's *New and Universal Dictionary of Arts and Sciences*, 1 vol. folio, 1751; and the *Complete Dictionary of Arts*

and Sciences, by Croker, Williams, and Clerk, 3 vols. folio, 1766. A somewhat better, though rather illogical performance was published by a "Society of Gentlemen" in 1754 in four 8vo vols., generally known as *Owen's Dictionary*, from the name of the publisher of it. The first rude outline of the ponderous and solid *Encyclopædia Britannica* was laid down in the year 1771, in three volumes, but it was nothing more than a dictionary of arts and sciences; it had not yet attained to its subsequent universality. Such is a brief outline of the earlier kind of encyclopædies.

2. The first E. proper that demands our attention is the *Encyclopædia Britannica*, of which the 2d comparatively complete edition, containing biographical and historical articles, appeared in 10 vols., between 1776 and 1783; the 3d edition was completed in 18 vols. in 1797; the 4th edition, in 20 vols., in 1810; the 5th and 6th editions, and supplements, in 6 vols., appeared between 1815-24; the 7th edition in 21 vols., in 1830-43; the 8th edition, in 21 vols., 1852-60; and a 9th edition was completed, 1889. The method pursued by this work, while thoroughly alphabetical, consists in a combination of the systematic and the particular. In few instances is any science broken up into fractional parts; nearly all the sciences are given in treatises as they severally occur in the order of the alphabet. In some cases, however, where obscurity might result from such a plan, the other method is adopted. A marked feature of this work, is the number of complete treatises and dissertations which it contains by men of European name. From first to last, this E. has been executed and published in Edinburgh, the literary reputation of which it has helped in no small degree to increase. The next E. that we must notice is the *Encyclopédie Méthodique par Ordre des Matières*, which was begun in 1782, and was not finished till 1832. It extends to 166½ vols. of text, with 51 "parties," containing 6,439 plates. Each subject is treated in a separate volume or series of volumes, so that the work is a collection of separate dictionaries, more extensive than any encyclopædic work that has yet appeared. A work of higher scientific value, however, and even of a more varied nature, has been in progress for nearly half a century in Germany, undertaken originally by Professors Ersch and Gruber in 1818, and which has since continued to appear, in three several sections of the alphabet, up to the present time. There have already appeared of this great *Allgemeine Encyclopädie der Wissenschaften und Künste* some 150 volumes. In 1802, Dr. Abraham Rees projected an extended and improved edition of Ephraim Chambers's *Cyclopædia*, which was completed in 45 volumes in 1819. The system of cross-references peculiar to E. Chambers is very effectually carried out in this book; but besides including a great accession of historical and biographical detail, it contained a large number of papers, prepared by competent writers, on subjects with which their life had rendered them familiar. Another work of considerable merit, which began to appear in 1810, was Brewster's *Edinburgh Encyclopædia*, edited by the late sir David Brewster, and completed in 18 vols., in 1830. In 1812, a great impetus was given to encyclopædic publications, by the appearance of the *Conversations-Lexicon* of F. A. Brockhaus, of Leipsic. It has since gone through fifteen editions. The eleventh issue, in 15 vols., appeared between 1864 and 1868 (supplement, 1872-73). The thirteenth edition appeared in 1888. This work has been translated into nearly all the civilized languages of Europe, no fewer than four English works of the kind being professedly founded on it: these are the *Encyclopædia Americana*, in 14 vols. (Philadelphia, 1829-46); the *New American Encyclopædia*, 16 vols. (New York, 1858-63), of which a new ed. under the title *American Cyclopædia* appeared between 1873 and 1876; the *Popular Encyclopædia*, 7 vols. (Glas., new ed. 1883); and Chambers's *Encyclopædia*, 10 vols. (Edin. 1860-68; new edition, 1889-93). Of these, the last-mentioned is a substantially new work, following in its construction the plan of the *Conversations-Lexicon*. A popular American Cyclopædia is *Johnson's Universal* in 8 vols. (1874-77, last ed., 1895).

The next encyclopædic work which appeared after the *Conversations-Lexicon*, was one projected according to an original philosophic plan by Samuel Taylor Coleridge, in 1818, and finished in 1845, in 30 volumes. This *Encyclopædia Metropolitana* was arranged in four divisions: 1st, the pure sciences; 2d, the mixed and applied sciences; 3d, biography and history; and 4th, miscellaneous and lexicographic articles. The contributions to the first two divisions were written by persons of recognized ability, and they have nearly all been published separately in 8vo volumes since the *Metropolitana* appeared. If the book had any fault, it was that the plan of it was too rigidly philosophical, and therefore not adapted to be consulted dictionary fashion; for although in one sense the alphabetic arrangement, by its jumble of subjects, is most heterogeneous and irrational, it recommends itself to popular acceptance by its extreme simplicity; and in point of fact, no E. has ever been thoroughly popular that has not been executed on the plan of a single alphabet, in which all subjects, however various, are included. Next appeared the *Penny Cyclopædia* of the society for the diffusion of useful knowledge, which was begun in 1833, and completed in 1843, in 28 volumes. This work was perhaps, at the time it appeared, the most useful and convenient, for the purposes of general consultation, of any encyclopædic treatise that had ever been issued. The *English Cyclopædia* is founded on the copyright of the *Penny Cyclopædia*, but is rearranged into four great divisions, which are each given in the order of the alphabet, viz., geography, natural history, biography, and arts and sciences. This publication was begun in 1853, and was completed in 1861, in 22 vols.; a synoptical index appeared in 1862, and a supplementary volume for each division has since (1869-73) been issued.

Among other publications of this character which have appeared in the course of the present century, may be mentioned Wilkes's *Encyclopædia Londonensis*, in 24 vols. 4to (Lond. 1810-29); the *Encyclopædia Perthenensis*, in 23 vols. (Edinburgh, 1816); and the *London Encyclopædia*, 22 vols. (Lond. 1829). The French have likewise published an *Encyclopédie des Gens du Monde*, in 22 vols. 8vo (Par. 1833-44); and *Encyclopédie Moderne*, which, with its supplement, occupies 43 vols. 8vo (Par. 1846-62); and a *Dictionnaire de la Conversation et de la Lecture*, 2d ed. in 16 vols. (Par. 1854-57), to which a supplement was afterwards added. The last of these is to a large extent based on the *Conversations-Lexicon* of Brockhaus. The most notable of the other German encyclopædias are Meyer's *Neues Conversations-Lexicon*, in 15 vols. (1857; 4th ed., 1890); and Pierer's *Universal Lexicon*, in 34 vols. (Altenburg, 1840-46), a sixth edition of which began to appear in 1875. In addition to these, there are several other continental encyclopædias, which are based upon the *Conversations-Lexicon*—such as the *Enciclopedia Española* (Madrid); the *Nuova Enciclopedia Popolare Italiana* (Turin); the *Nordisk Conversations-Lexicon*, 5 vols. (Copenhagen, 1858-63); and the *Seenskt Konversations-Lexikon*, 4 vols. (Stockholm, 1845-51); besides others in Russia, Hungary, the Netherlands, etc.

The *International Cyclopædia* appeared in 1885. Its purpose was to combine the best features of all previous works as tested by experience, and especially to serve the convenience of readers by subdividing topics, multiplying titles, and greatly facilitating its use by a very careful system of cross-references. It contains some 50,000 titles and many hundreds of illustrations.

3. We have now to speak of those books that are encyclopædias of some one special branch of knowledge. Such works have always been very numerous both in America and in Europe. Such are the *Biographie Universelle* (1811; 2d ed., 1865); Cuvier's *Dictionnaire des Sciences Naturelles*, 60 vols. (1845); McCulloch's *Commercial Dictionary* (2d ed., 1882); Bouvier's *Law Dictionary* (1885); McCulloch's *Geographical Dictionary* (2d ed., 1866); Lippincott's *Gazetteer* (1882); Morton's *Cyclopædia of Agriculture* (1855); Lalor's *Cyclopædia of Political Science*, 3 vols. (1885); Gwilt's *Encyclopædia of Architecture* (1888); Smith's *Dictionary of Greek and Roman Geography*, 2 vols. (1857); *Dictionary of the Bible*, 3 vols. (1863); *Dictionary of Greek and Roman Biography and Mythology*, 3 vols. (2d ed., 1851); *Dictionary of Greek and Roman Antiquities*, 2 vols. (3d. ed., 1891); McClintock and Strong, *Cyclopædia of Biblical, Ecclesiastical and Theological Literature* (1880); Allibone's *Dictionary of British and American Authors* (1871); Hackett and Laing, *Dictionary of Anonymous and Pseudonymous Literature* (1888); Chambers's *Cyclopædia of English Literature* (4th ed., 1885); Ure's *Dictionary of Arts, Manufactures and Mines* (7th ed., 1877); Peck, *A Dictionary of Classical Literature and Antiquities* (1895); Spon's *Dictionary of Engineering* (1874); Wood's *Reference Handbook of the Medical Sciences* (1889); Percy Smith's *Glossary of Terms and Phrases* (1883); Bartlett's *Dictionary of Americanisms* (2d ed., 1859); Bohn's *Dictionary of Classical Quotations* (1882); Hughes, *Dictionary of Islam* (1885); Fremy, *Encyclopédie Chimique* (1883); Sonnenschein's *Cyclopædia of Education* (1889); Bartlett's *Familiar Quotations* (8th ed., 1885); Houston's *Dictionary of Electrical Words, Terms, and Phrases* (1891); Stephen's *Dictionary of National Biography* (1891); Appleton's *Cyclopædia of American Biography* (1890); Sonnenschein's *Cyclopædia of Education* (1889); Scribner's *Cyclopædia of Music and Musicians* (1888); and Bliss's *Cyclopædia of Missions* (1891).

ENCYCLOPÉDISTES. See ENCYCLOPÆDIA.

END. This familiar word is concerned in some important discussions, and especially in ethics. It is in the sense of "the thing aimed at," the object, purpose, or goal of human action, that we have here to consider it. There is a fundamental contrast between science and art, knowledge and practice. Science, or knowledge, embraces the general order of the universe, and states that order in the form by which we can take in as much as possible in one view; it is the fullest intellectual comprehension of the phenomena of nature that the mind can attain to. Art, or practice, on the other hand, selects and appropriates certain items of knowledge, so as to subserve some useful purpose, some exigency of human life. Thus, agriculture, navigation, law, politics, education are all branches of practice; they involve knowledge, but in strict subordination to their several purposes. The navigator studies astronomy, not with a view to enlighten his understanding as to the mysteries of the solar system and the starry sphere, but with a view to the guidance of his course in the sea. In short, to an art (the word is not here used in the narrow sense of a fine art), or a department of practice, belongs in the first place the consideration of the *end*. Every art has its *E.*, which is its distinction from every other. In most of the arts, the *E.* is clear and unmistakable; we all know what is expected of a builder, a soldier, or a judge; the only question is how to obtain the knowledge requisite for adequately performing each separate function. But there are some departments where the *E.* itself is not agreed upon, which casts a peculiar difficulty on the practice. Thus, it was remarked under CIVILIZATION, that the *E.* of the whole mechanism of human society, including politics, etc., is differently viewed by different minds. But it is in the one special department of morality that the consideration of the *E.* is of most vital consequence. This feature of the ethical problem has been very little adverted to in modern discussions, while the ancient philosophers kept it more prominently before them. Aristotle

begins his *Ethics* by remarking that every art aims at some good; most arts, as medicine, ship-building, generalship, having limited or partial ends; while some comprehend much wider ends than others. The largest E. of all is the good of mankind collectively. Hence he goes on to inquire what is the highest good of man, and finds that happiness is neither pleasure, nor honor, nor virtue (by itself), nor wealth, but that it is "an energy of the soul according to virtue;" activity, in opposition to oriental notions of luxurious repose, being an essential in his eyes. He has next, therefore, to inquire what "virtue" is, according to which a man must employ his activity—a question of no easy solution. Still, the discussion brings out the one fact, that morality is a branch of practice, but unlike most arts in this, that the E. is peculiarly difficult to determine precisely. Accordingly, it is necessary to have in connection with it a set of discussions, called by Mr. J. S. Mill (*Logic*, concluding chapter) teleology, or the doctrine of ends, corresponding to what the German metaphysicians have termed the principles of practical reason. The various theories of moral obligation differ in their statement of the E. of morality; according to one, it is the self-interest of the individual; according to another, the interest of mankind on the whole. See *ETHICS*.

ENDEMIC (from *en*, among, and *demos*, the people), a term applied to diseases which affect numbers of persons simultaneously, but so as to show a connection with localities as well as with their inhabitants. Endemic diseases are usually spoken of as contrasted with epidemic (q.v.) and sporadic (q.v.); the first term indicating that a disease infests habitually the population within certain geographical limits, and also that it is incapable of being transferred or communicated beyond those limits; while, on the other hand, a disease is termed epidemic if it is transmitted without reference to locality; and sporadic if it occurs in isolated instances only. The theory, accordingly, of E. diseases is, that they are in some way or other connected with the soil—the result of terrestrial influences, or *miasms*—of poisons generated within the earth, or near its surface, and diffused through the air, so as to be weakened in proportion to the distance from the source of the poison. Such poisons are always observed to be more virulent in summer than in winter—more dangerous at night, when the vapors are concentrated on the surface of the soil, than in the day-time—more abundant in the plains, and in close confined places, than at a certain degree of elevation—more easily carried in the direction of the wind than in the opposite—and very often arrested altogether by water, or by a belt of forest or other luxuriant vegetation. In all these particulars, *endemic* are different from *epidemic* diseases, which bear no very obvious relation to the soil, and are not observed to be considerably modified either by the prevailing winds or the period of the day or night at which exposure to their influence takes place. The most marked type of an endemic disease is *ague* (q.v.) or intermittent fever, which has all the habits mentioned above, and is to so marked a degree a denizen of particular tracts of country as to lead to their being in some instances almost depopulated. Many places in Italy are a prey to the *aria cattiva* or *malaria*, as it is popularly called; and hence, no doubt, even more than for protection from human foes, the custom so prevalent in that country of building the villages on the tops of hills, so as to secure immunity from the poisonous vapors raised by the solar heat from the plains lying on either side at the base of the Apennines. Terrestrial *miasms*, or such poisons as generate E. diseases, are usually found in the neighborhood of marshy flats, or of uncultivated tracts of land at the confluence of rivers, or where a *delta*, or a wide channel subject to overflow, is formed at the upper end of a lake. In proportion, too, as the heat of the sun is greater, the tendency to malarious emanations is increased; and in the tropics, accordingly, large tracts of jungle and forest are often rendered absolutely uninhabitable and almost impassable at certain seasons, by the invisible and odorless germs of intermittent, remittent, and even continued fevers (q.v.), which are more fatal and unmanageable than the most terrible epidemic pestilence to those who are exposed to them. Such diseases are almost always sudden in their mode of attack, and they indicate the range of their influence by the number of persons attacked; but they are wholly free in most cases from the suspicion of communication by contagion (q.v.), which is so frequent in the case of epidemic diseases. The precise nature of the malarious poison has never yet been discovered with any approach to exactness. It is known, however, to be almost invariably checked by drainage and cultivation of the soil.

EN'DERBY LAND, discovered by Biscoe in 1831, lies in lat. 67° 30' s., long. 50° east. It appeared to the discoverer to be of considerable extent, and was closely bound by field ice, but owing to stress of weather and the extreme cold, it could not be approached within 20 or 30 m., and Biscoe was thus unable to say whether the land he discovered was an island or a strip of continental coast.

ENDERMIC AND HYPODERMIC METHODS OF TREATMENT. These terms are, as the names imply, used to designate certain methods of making the skin an agent for the reception of medicines. The endermic method consists in raising a blister by the ordinary process, opening it by a small puncture, which must not be at the lowest part of the bladder, gently pressing out the fluid contents, and then injecting a medicinal solution, by means of a small syringe, through the puncture into the emptied sac; or, if the medicine is in the form of powder, it may be scattered over the raw surface. The endermic method is now almost entirely superseded by the hypodermic method, in

which medicines are introduced into the subcutaneous cellular tissue by means of a very finely pointed syringe. For the invention of this process, the science of medicine is indebted to Dr. Alexander Wood of Edinburgh. It is chiefly, but not solely, to anodynes that these methods are especially applicable. It has been found that morphia given by Dr. Wood's method acts more speedily and more powerfully than when given by the mouth: moreover, the medicine given in this way does not disturb the functions of the stomach, and may be administered in those cases of irritation of that organ in which medicines introduced into it would be rejected by vomiting. A solution of acetate of morphia, carefully freed from any excess of the acid, and of such strength that three minims shall contain one third of a grain, is commonly employed, the dose varying from one to three minims, or from one ninth to one third of a grain of the salt. If the general effects of the morphia (as relief of pain and sleep) are required, any convenient part of the body, as, for instance, the fore-arm, may be selected: the skin, pinched up between the fore-finger and thumb of the left hand, is penetrated by the point of the syringe, and the solution injected. When a local action is required, as in the case of various forms of neuralgia, the solution should be injected as near as possible to the seat of pain. As some patients are remarkably susceptible to the action of morphia administered in this method, it is advisable to begin with the smallest of the above-named doses.

A scientific committee appointed by the Royal Medical and Chirurgical Society of London to investigate the physiological and therapeutical effects of the hypodermic method of injection, have sent in an elaborate report, which was read in June, 1867. Amongst the most important physiological facts which were observed, the following may be especially mentioned. Watery solutions of drugs subcutaneously injected were far less rapid in their action than when they were introduced into a vein. On comparing the effects of medicines subcutaneously injected with those produced when they were administered by the mouth, or by injection into the lower bowel, it was found that, in the case of some drugs, the local action was different according to the mode of administration, although the general effects produced were of the same kind. Thus, aconitine given by the mouth affected the salivary glands; when given by the rectum, it caused irritation of the gut; and when given by the skin, it occasioned local pain. The smallest dose fatal to rabbits was, by the mouth, $\frac{1}{100}$ th, by the rectum, $\frac{1}{100}$ th, and by the skin, $\frac{1}{100}$ th of a grain: it was thus five times as energetic when given subcutaneously as when given in the most usual way. The effects of morphia when injected under the skin were also more rapidly manifested and more intense than when given by the mouth or rectum. A solution of podophyllin, which, when administered by the mouth, acts as a powerful cholagogue (bile-provoking) aperient, when injected into the skin, gives rise to free action of the kidneys. The investigations of the therapeutic value of this mode of administering drugs were limited by the fact, that many substances (aconitine, for example) give rise to great local irritation when used subcutaneously. In cases of simple neuralgia, atropine was found to have a very beneficial effect when thus given, and in some cases more permanent relief followed its injection than that of morphia. The value of the latter drug was found to be much increased by this method, the required action being of longer duration, and being produced with greater rapidity and intensity. The same advantages followed this mode of giving quinine in intermittent fevers, but some caution is requisite in giving large doses, as irritation may arise from its presence under the skin. Amongst the conclusions at which the committee arrives are the following: (1) That, as a general rule, only clear neutral solutions of drugs should be employed, decidedly acid or alkaline solutions being apt to cause irritation, and even local ulcers, at the point of application; (2) that, as in the case of podophyllin, symptoms are observed to follow the administration of some drugs by the skin, which are wanting when the same drugs are otherwise administered; and (3) that the advantages to be derived from this method of introducing drugs are (*a*) rapidity of action, (*b*) intensity of effect, (*c*) economy of material, (*d*) certainty of action, (*e*) facility of introduction in certain cases, and (*f*) in some drugs, the avoidance of unpleasant symptoms.

ENDICOTT, JOHN, 1589-1665; b. England. He was sent out by the Massachusetts company in 1628, to oversee the plantation at Salem. He was deputy-governor of Massachusetts for five years, and governor in 1644-49, 1651-54, and 1655-56. He was a rigid puritan, zealous and intolerant in administration after the fashion of those times. While he was governor, four Quakers were executed for defying the law which banished them from the colony on penalty of death if they should return.

ENDICOTT, WILLIAM CROWNINSHIELD, b. Salem, Mass., 1827. He is said to be the oldest lineal descendant of John E., the first gov. of Mass. He graduated from Harvard univ., 1847; was admitted to the bar, 1850; was a member of the Salem common council; was city solicitor, 1858-63; and was called to the Supreme bench, 1873. Mr. E. has never held an elective public office. As the dem. nominee for gov., 1884, he was defeated by George D. Robinson. He was appointed sec. of war by Pres. Cleveland, 1885. He is one of the overseers of Harvard univ., and a member of the Mass. Historical Society. He was an old-line Whig until 1860.

ENDIVE, *Cichorium endivia*, an annual or biennial plant, of the same genus with chicory (q. v.), said to be a native of China and Japan, but which is naturalized in the

Levant, and has long been in cultivation as a garden vegetable, its blanched root-leaves being much used as a salad, and also sometimes for stewing and in soups.

ENDLESS SCREW, a screw combined with a cog-wheel, or one acting on the threads of a "female" screw sunk in the edge of a wheel. When the axis of the screw is at right angles to the plane of the wheel—that is, when the screw acts on a spur wheel—it is known as the American form.

ENDLICHER, STEPHEN LADISLAS, a distinguished botanist, was b. at Pressburg in Hungary, June 24, 1804. He was educated in his native town, Pesth, and Vienna, and then entered the church which he, however, abandoned in a few years. In 1827, he commenced his botanical and linguistic studies, and in the following year he was placed at the head of the imperial library at Vienna. In 1836, he was appointed keeper of the museum of natural history at Vienna, and in 1840, he became professor of botany in the university, and director of the botanic gardens. E. was much disturbed by the turn political events had taken in 1848, fell into a state of gloom, and in Mar. 28, 1849, put an end to his own life. A few of his works are upon ecclesiastical subjects, but the great bulk of his writings are botanical, the most important being connected with the systematic arrangement of plants. One of his earliest works was *Flora Posoniensis* (1830): in which he describes the plants growing in the neighborhood of Posen arranged according to the natural system. His most important work *Genera Plantarum secundum ordines naturales disposita*, appeared from 1836 to 1840. In it he follows out with great elaboration the system of natural arrangement. It has had great influence on succeeding botanists, and is still one of the most complete works upon systematic botany.

ENDOCARDITIS, disease of the internal surface of the heart, resulting in the deposit of fibrin upon the valves. See HEART, DISEASES OF.

ENDOCHROME (Gr. *endon*, and *chroma*, interior color), the coloring matter contained in the tissues of the lower classes of plants. It is a modification of chlorophyll, which gives the green color to the leaves of the higher classes of plants; when the chlorophyll changes its color in the autumn, in consequence, probably, of the retention of the oxygen element of carbonic acid, it is then not strictly chlorophyll, and may be called endochrome. Some chemists say that endochrome and chlorophyll have the same constitution, but it must be remembered that chlorophyll changes in accordance with the action of light.

ENDOGENOUS PLANTS, or ENDOGENS (Gr. *endon*, within, and *genos*, birth or origin), one of the great classes into which the vegetable kingdom is divided, the others receiving the corresponding designations of *exogenous plants* and *acrogenous plants*. The character from which this designation is derived is found in the structure of the stem, which does not increase in thickness by additional layers on the outside like the *exogenous* stem, familiarly illustrated in all the trees of the colder parts of the world, but receives its additions of woody matter in the interior; and in general does not continue to increase indefinitely in thickness like the exogenous stem, but is arrested when a certain thickness has been attained, different in different species, and afterwards increases only in length. When a transverse section is made of an endogenous stem, numerous bundles of vessels are seen dispersed irregularly in cellular tissues, the younger and softer parts of the stem exhibiting the cellular tissue in greatest proportion, the older and lower parts chiefly abounding in vascular bundles, which are, however, somewhat scattered in the central part of the stem, and are densely aggregated towards the circumference, there, in the palms generally, forming very hard wood, in some of them wood so hard that it cannot be cut with a hatchet. The stems of E. P. in the far greater number of cases produce terminal buds only, and not lateral buds, and are therefore unbranched. From the bases of the leaves, definite bundles of vascular tissue converge towards the center; but these extending downwards extend also outwards, and thus an interlacing of fibers takes place, which contributes not a little to the strength and compactness of the wood in the lower part of the stem. As the fibers extend downwards, they also become attenuated, spiral and porous vessels disappearing, and nothing but the most ligneous substance remaining. It is the hardening of the outer part of the stem which arrests its increase in thickness. Endogenous stems have not a distinct *pith* nor any *medullary rays*. When the central part is soft and pith-like, yet it is not distinctly separated from the surrounding wood, and has no *medullary sheath*. In many E. P., as in the greater number of grasses, the center of the stem is hollow. This is not the case at first, when the stem begins to grow; and when any cause makes the growth of the stem unusually slow, so that it is much stunted, it remains solid; the fistular character of the stem is the result of its rapid growth, rupturing the cells of the central portion, which finally disappear. Endogenous stems have no *cambium* and no proper *bark*. There is, indeed, a cellular *epidermis*; and there is also within it, and exterior to the hardest woody part of the stem, a comparatively soft layer of a corky substance, which is sometimes called bark, sometimes *false bark*, which does not separate from the wood below it without leaving myriads of little broken threads, the ends of the fibers which have extended into it from the hardest part of the stem. In those exogenous plants which produce lateral buds and branches, the fibers of the branches on descending to the stem extend on the outside of the proper stem, between its hardest portion

and the false bark; and in this way a great thickness is sometimes attained, as in the dragon-tree. In the grasses, a *plexus* of fibers takes place at the nodes, the fibers crossing from one side to the other. No British tree—and it may almost be said, no tree of temperate or colder climates—is endogenous. Almost all the endogenous trees are palms, although a few, as the dragon-tree, belong to other orders. E. P., however, are numerous in all parts of the world. Among E. P. are many of the plants most useful to mankind, particularly palms and grasses, all the true corn-plants being included among the latter. Nutritious substances are very extensively produced both in the fruit or seed, and in other parts; poisonous products are comparatively rare, although found in the *araceæ*, *liliaceæ*, *melanthaceæ*, and other orders. Aromatic secretions are characteristic chiefly of one order, *scitamineæ*. Besides palms and grasses, many of the E. P. are of great beauty, and many produce most beautiful flowers. Lilies and orchids may be mentioned as instances.

E. P. are *monocotyledonous*; and the terms *endogenous* and *monocotyledonous* are therefore often employed indiscriminately to designate the class. But Lindley distinguishes a class of *dictyogens* (q.v.), which, although monocotyledonous, have stems approaching to the exogenous character. The leaves of E. P. generally exhibit parallel venation, which is indeed strictly confined to them, although a venation resembling it, or rather simulating it, may be seen in some exogenous plants. The seed also germinates in a peculiar manner, different from that of exogenous plants, and to which the name *endorhizal* has been given, the radicle being protruded from within the substance of the embryo, and surrounded by a cellular sheath formed from the integument which it breaks in its egress.

ENDORSE. See PROMISSORY NOTE:

ENDORSE, in heraldry, an ordinary containing the fourth part of a pale. *Endorsed*, again, or *indorsed*, signifies that objects are placed on the shield back to back.

ENDOSMOSE AND EX OSMOSE (Gr. inward motion and outward motion), terms applied by Dutochet, the first investigator, to the transfusion that takes place when two liquids or two gases of different densities are separated by an animal or a vegetable membrane. As the transmission has no necessary relation to outwards or inwards, the term *osmose*, or *osmotic action*, is now preferred. See **DIFFUSION**.

This action performs a very important part in living organisms, and explains many phenomena of the circulation of sap and the processes of nutrition, which were previously referred only to the wonderful action of vital energy. Thus, the blood continually streaming through the capillary vessels gives forth a portion to the surrounding cells, and so supplies them with the necessary chyle. This may, however, by the expansion of the capillary vessels (see **INFLAMMATION**), lead to immoderate exudation. On the other hand, the blood, in passing by, takes up a number of worn-out constituents of the juices of these cells, and in this way serves, by the exchange which it effects, to restore the body, and to disburden it of products which have become useless.—In plants also, osmose performs an important part in the process of nutrition and the motion of the sap. The substances in the cells of plants are usually denser than the fluids without, and thus a process of endosmose takes place, by which the plant is supplied in the first instance from the soil, being incapable, however, of appropriating any nourishment which is not presented in a liquid state to the fibrils of its roots; whilst that which the roots give off by exosmose, is supposed gradually to unfit the soil for the growth of the same kind of plant. The bursting of the capsules of some kinds of plants is owing to a process of endosmose going on in the cells, as in the fruit of the elaterium or squirting cucumber. Some of the *entozoa*, as tape-worms, seem to live entirely by *endosmose*. See **OSMOSE**.

ENDOWED SCHOOLS ACTS. The restrictions placed upon the endowed schools of England, both those of royal and private foundation, in regard to terms of admission, course of study, etc., were found inconvenient and injurious to the schools, and the power of parliament was invoked to make certain needful changes; and during the present reign several statutes have been enacted for this purpose. The act 3 and 4 Vict. c. 77 empowered courts of equity to make decrees or orders extending the systems of instructions and the right of admission to any school, and to establish schemes for the application of its resources, having due regard to the intentions of the founder. The act 23 Vict. c. 11 required the trustees and governors of endowed schools to make such order as, without interfering with the religious teaching of the other scholars or authorizing any new religious teaching, should admit children of other denominations than that to which the foundation belongs, except where the foundation expressly requires the children to be instructed according to the formularies of such denomination. The most important public schools—Eton, Harrow, Westminster, etc.—were exempted from the operations of these acts. Another act annexed certain conditions to the appointment of officers in endowed schools. The act of 1869 is most important of all. It authorizes the appointment of commissioners, “with power in such manner as may render any educational endowment (with certain specified exceptions) most conducive to the education of boys and girls, and either of them, to alter and add to any existing, and to make new trusts, directions, and provisions which affect such endowment and the education promoted thereby.” A subsequent act continues and amends the act of 1869,

and one still later transfers the power of the endowed school commissioners to the charity commissioners.

ENDRÖD, a village of Hungary, in the county of Bekes-Csanaad, on the Körös, 90 m. e.s.e. from Budapest. Pop. 10,900. The surrounding district produces much corn.

ENDYMION, in Greek mythology, was a son either of Zeus or of Æthlios, and followed, according to some accounts, the occupation of a herdsman or hunter, but according to others, was king of Elis. On account of his uprightness, he is said to have received, at his own request, from Zeus, the gift of immortality, unfading youth, and everlasting sleep; but another version is, that Zeus having taken him up to Olympus, E. fell in love with Here (Juno), and was condemned by her enraged husband to eternal sleep on mount Latmos. Others, again, prettily fable that Selene (the moon), charmed by the beauty of the youth, conveyed him to Caria, and sent him to sleep on mount Latmos, that she might nightly kiss him unobserved. The Eleans, on the contrary, declared that he died among them, and in proof of it were wont to show his monument. The myth of E. has been happily interpreted by Max Müller in his article on comparative mythology, in the *Oxford Essays* (1856). E., according to him, is one of the many names of the sun, but with special reference to the setting or dying sun, being formed from *enduo*, probably a dialectic variety of *duo*, the technical verb in Greek to express sunset. E. sleeps in the cave of Latmos, i.e., of night (from the same root as *leto* or *latona*, the night). So far the myth poetically describes certain phenomena of nature, the sinking of the sun in the west, and the rising of the moon, that seems to follow his departing beams. But the original signification of the metaphors becoming lost, as might naturally happen when the words expressing them had only a local usage, it was, we may say, inevitable that people should transfer the metaphors to persons, and invent a history to supply the place of the vanished poetry. And this invention, or more properly, explanation (for it was doubtless made in all good faith), is what properly constitutes the myth of Endymion. The story has been made the subject of a poem by Keats.

ENE MA (Gr. *en*, in, and *ēmi*, I enter), a medicine or fluid substance conveyed into the body by friction, usually through the rectum or lower bowel. See **CLYSTER**.

ENEMY, in international law signifies either a nation at war with another, considered as a whole, or an individual or body of men belonging to the hostile nation. By ancient practice to constitute a lawful enemy there should be a public declaration of war made to the nation against which hostilities are intended. Such a declaration was considered to be demanded by the ordinary laws of humanity and fair dealing. In modern times it is held that all that is requisite is a public proclamation of war made by a nation within its own territory; this answers all the demands of formality, apprises neutral peoples of the impending war, and is so public in its character (under modern conditions) that the enemy must be presumed to have taken notice of the declaration.

Under monarchical governments the right of declaring war against a public enemy is universally reserved to the crown; in the United States the constitution gives to Congress the power "to declare war, grant letters of marque and reprisal, and make rules concerning captures on land and water;" thus making it the duty of that body to define who are the public enemies, and to prescribe the rules for their treatment. It has been a mooted question whether a nation at war should treat all the subjects of a hostile country as enemies individually, or only the nation itself, regarded in its corporate capacity and as represented by its authorized forces—its army and navy. The tendency has been in recent times strongly towards the latter theory; private individuals not commissioned to bear arms and not taken in the act of hostility are now by civilized nations treated with all possible humanity and forbearance. It was a corollary of the old theory that all individuals of a hostile state were enemies, that the property of aliens residing in a country with which their own was at war might be confiscated, and even that they might be made prisoners. It is to be doubted if such action would to-day be taken by any civilized nation, unless, possibly, in the way of reprisal. In regard to the treatment of enemies there has been a great advance in the humanity and forbearance of the rules governing the carrying on of hostilities. In the civil war in the United States a code of rules was adopted which was drawn up by the well-known publicist, Professor Lieber, and this code has served as a basis for rules subsequently adopted by international conference in Brussels (1874) and Oxford (1880). By all these codes what is allowable in war is, speaking generally: the destruction or injury of enemies in arms by ordinary methods of warfare; the destruction of property when necessary to carry on operations of war, or to reduce the military strength of the enemy; such incidental injury to persons or property of non-combatants as the operations of war make unavoidable. Killing or wounding, except in battle, or regular military operations, the use of poison, the use of cruel or unusual weapons, wanton destruction of property—all are strictly forbidden.

ENERGICO, an Italian term in music, meaning with energy and force; with strong articulation and accentuation, and a marked powerful delivery of the single notes, without losing in distinctness of execution.

ENERGUMENS, a class of persons, who in the early ages of the church were believed to be possessed by evil spirits, and were placed under the special care of exorcists, yet allowed a certain amount of participation in religious services. Catechumens included

in this class could not be baptized, except in cases of sickness; while the faithful who became deranged were obliged to remain apart from their fellow Christians, in the area of the church, which was not enclosed, deriving from this circumstance the name of *χειμαζόμενοι*—exposed to the weather. They could not partake of the Lord's Supper, except upon their death-beds.

ENERGY. See **FORCE**, **THERMO-DYNAMICS**.

ENFANT GÂTÉ (Fr., "spoiled child") is a term used in polite society in France to denote a person who has been reared in luxury, and is devoted to a life of inactivity and ease.

ENFANTIN, **BARTHÉLEMY PROSPER**, the chief representative of St. Simonism, and as such, usually styled père Enfantin, was the son of a banker at Paris, where he was born Feb. 8th, 1796. He became a pupil in the *Ecole Polytechnique* in 1812, but was expelled in 1814, in consequence of his having joined the pupils who left school and fought against the allies on the heights of Montmartre and St. Chaumont. He was afterwards a commercial traveler in Russia, then a banker's clerk, and in 1825, became director of the *Caisse Hypothécaire*. About this time, he became a disciple of St. Simon, whose ideas he developed, after the death of their author, in the *Producteur*. After the July revolution, E. associated himself with M. Bazard for the active propagation of St. Simonism. Bazard preached it in its relations to philosophy and politics; E. mainly in its relations to the social state. Soon, however, a schism broke out between the two on the question of marriage and the relation of the sexes. Recognizing the "mobility" of the affections, E. affirmed that they ought to be "free," and of course pronounced against the ties of marriage. E.'s views were pushed so far, that government deemed it necessary to interfere on the grounds of public decency. The "supreme father" (as his disciples were wont rather profanely to call him) was, after a trial of two days, sentenced to two years' imprisonment, and to pay a fine of 100 francs. Being released at the expiration of a few months, E. went to Egypt, and, after an absence of two years, returned to France, and became a postmaster and farmer in the vicinity of Lyons. In 1841, he came to Paris, and was appointed a member of the scientific commission for Algiers, and on his return from Africa, wrote a sensible, interesting book, entitled *Colonisation de l'Algérie* (Paris, 1843). After the revolution of 1848, he edited the journal entitled *Le Crédit Public*, a paper retaining much of the old St. Simonian character, but which had to stop in 1850 for want of funds. E. afterwards held an important situation on the Lyons and Mediterranean railway. His principal works are his *Doctrine de St. Simon*, in conjunction with others (1830); his *Traité d'Economie Politique; La Religion Saint-Simonienne* (1831); *Moral; Le Livre Nouveau* (1832); *Correspondance Philosophique et Religieuse* (1847); *Correspondance Politique* (1849); *La Vie Eternelle, Passé, Présent, Futur* (1861). He died Aug. 31, 1864.

ENFANTS PERDUS. (Fr., "lost children.") English equivalent, "A Forlorn Hope" (q.v.). The term is a military expression meaning formerly the officers and men who were appointed, or who volunteered, to lead the way in some especially dangerous assault; a work now performed by those next in order on duty.

ENFANT TERRIBLE (Fr.), literally, *terrible child*, one given to making inconvenient remarks, more or less clever, and mostly personal, to the confusion of present company.

ENFEOFFMENT. See **FEOFFMENT**.

ENFIELD, a town in Hartford co., Conn., on the Connecticut river, and the New York, New Haven and Hartford railroad, 18 m. n. of Hartford; contains two villages. There are carpet factories, bicycle works, steam brick works, and extensive powder-mills, the latter said to be the largest in the world; several churches, banks, public library, sanitarium, electric lights and street railroad, and a high school. In the town is Shaker station, a community of Shakers. Pop. town, '90, 7199.

ENFIELD, a t. in Middlesex, England, 10 m. n.e. of London, noted as the place of manufacture of the Enfield rifle, now the Martini-Henry rifle; pop. '91, 31,532. In the place are the remains of a royal palace in which Edward VI. kept his court.

ENFIELD, a tp. in Halifax co., N. Car.; traversed by the Wilmington and Weldon railroad, and containing the town of Enfield. Pop. '90, tp. 3650, town, 568.

ENFIELD, WILLIAM, LL.D., an English author and dissenting minister, was born in Sudbury in 1741, and died at Norwich in 1797. He was educated at Daventry under Dr. Ashworth, and on leaving the seminary officiated in a Unitarian church at Liverpool, then removed to Warrington, where he was resident tutor and lecturer on belles-lettres in the academy at that place. In 1785 he became pastor of the Unitarian church at Norwich. He aided Dr. Aikin in preparing his *General Biographical Dictionary*, and published *A History of Philosophy*, an abridgment of Brucker's work (1819); *The Preachers' Directory*, a work that became very popular (1771); *Sermons for Families* (1778); and *The English Preacher* (9 vols.). A memoir was written by Dr. Aikin.

ENFIELD RIFLE-MUSKET, so called, deriving its name from the place of its manufacture in England, was a kind of small-arms resembling the old Springfield rifle-musket.

ENFILADE is a military term applied to a fire of musketry or artillery made in the direction of the length of a line of troops or a line of rampart. A besieging battery so placed as to send its shot along any part of the line of a fortification, and inside the parapet, does great execution in dismounting the guns, which thus present the largest surface to the balls. Hence the lines of rampart should be planned that their prolongations may fall in situations inaccessible to the enemy. Where this is not possible, the lines are either broken, or are protected by bonnets (q.v.), or by traverses (q.v.), or blindages (q.v.). In the siege of a fortress, the trenches of approach are cut in a zigzag, to prevent the defenders enfilading them from the walls.

ENFRANCHISE, ENFRANCHISEMENT, to make free; the admission to certain liberties or privileges. Thus, a person made a denizen of the country, or receiving the freedom of a city or burgh, is said to be enfranchised.

ENGADINE, a famous valley in Switzerland, in the canton of Grisons, second only to the Valais in length, extends n.e. for about 50 m. along the banks of the Inn, from the foot of Mt. Maloja to the village of Martinsbruck. It is divided into two portions—that toward the s.w., called the Upper E., and that toward the n.e., the Lower Engadine. The latter is wild and bleak, pent up within narrow limits among the hills, and having a huge barrier of glaciers between it and Italy. The upper E. has a remarkably invigorating climate and is a resort for consumptives. It contains the village of St. Moritz. The Inn, which enters the valley at its s.w. or upper extremity, and flows through it, has many towns upon its banks, the highest of which, Silvaplana, is about 6,000 ft. above sea-level.

ENGAGEMENT, MILITARY. See **BATTLE**. It is of interest to note how, since 1880, the scientific theories of the conduct of a battle are rapidly being modified by the recent inventions of more effective instruments of destruction. Most important among these discoveries are: (1), the great increase in the range of artillery; (2), the invention of rapid-fire and machine-guns; (3), the perfection of the magazine-rifle; (4), the discovery of new explosives of tremendous power, such as dynamite, melinite, écrasite, emmensite, and roburite; and, (5), the invention of smokeless powder.

No great conflict has arisen since the adoption of these new appliances for war, to test them by the practical experience of the battle-field; but already the theory of military engagements has been seriously modified by modern tacticians. A recent writer has made some interesting remarks upon this head.

"As might be expected, the fundamental principles of war are the same, but a thousand circumstances have modified the phenomena which they display. For example, in one of the essential conditions of victory: when Napoleon said that fortune always favored big battalions, he was merely stating the truism that the surest way of beating a hundred men is to attack them with two hundred. Hence the strategist is always endeavoring to get the greater military force at a particular place and at a particular moment. From these premises arose Napoleon's favorite manœuvre—a manœuvre similar to that of 'breaking the line' at sea. Napoleon liked to drive his army like a wedge into the middle of his opponents. This done, he hit out left and right, and drove back the disunited enemy on separate lines of retreat. Then came in the application of the rule that the greater beats the less. He singled out one or other half of the divided army of the enemy for attack, and crushed it with his whole strength. To do this, he swiftly brought over, say, the left wing of his army, joined it to the right, and then threw his united force on one-half of the army opposed to him. As a rule, numbers prevailed; he crushed his foe, and then hurled himself on the other and still unconquered half. Now, it might be supposed that this operation must remain as practicable now as it was a hundred years ago. Oddly enough, however, it is no longer sound generalship. And for this reason, a modern army, partly from its size, possesses much greater possibilities of delay and of fighting a waiting battle, than did those of two generations ago. A weaker force, that is, can more easily hold in play a stronger. Hence, when A's force has united and tries to crush one-half of B, that half is able to hold A in check till the other half comes up and unites with it.

"If it were possible for an army of our day, supplied with all the implements with which modern science has provided it, to meet an army of equal numbers equipped as Napoleon's armies were equipped, the difference in power of the modern army would be such that it would almost be able to deal with its enemy as civilized armies provided with fire-arms were at first able to deal with savages possessed only of bows and arrows. The artillery of the days of Napoleon would not be able to act at all, for our modern infantry can fire with effect at a distance greater than could Napoleon's big guns. Our artillery would be able to destroy Napoleon's army before either his artillery or infantry could act against us. Thus, an army of 50,000 men of our own time must be reckoned as possessing at least the resisting power of 100,000 of the days of Napoleon. It is obvious, therefore, that the relationship between time, distance, and the resisting power of armies has been greatly affected by the change in the character of the weapons; and that calculations as to what a superior army can do in a given time to break up the force of an army opposing it, and to be free to deal with another army, are greatly modified." See Maurice, *Modern War* (1891). ENG AND CHANG. See SIAMESE TWINS.

EN-GEDI (meaning in Hebrew "the fountain of the kid," and corresponding to the Arabic "Ain Jidy") is the name of a wilderness, a mountain pass, a ruined village, and a perennial fountain on the w. side of the Dead sea, half way between its northern and southern ends. In the days of Abraham it was the site of a city named Hazezonta-mar, *cutting of palm trees*, doubtless with reference to the grove of trees which then grew around the fountain. In its strongholds was the home of the Amorites, who were, at that time, attacked and destroyed by the Assyrians and their allies. Here in "the city of palm-trees," at the time of the exodus from Egypt, a branch of the Kenites lived concerning whom Balaam said—"Strong is thy dwelling place, and thou puttest thy nest in the rock." After the conquest of Canaan they left this fortress and went up to dwell with the tribe of Judah. Four hundred years later, David fled for refuge into the strongholds of En-gedi. When Saul heard this he "took 3,000 chosen men and went to seek David and his men on the rocks of the wild goats." Entering one of the numerous caverns, it proved to be the very one in the sides of which the fugitives were concealed. David, refusing to lift his hand against the king, and forbidding his followers to touch him, cut off the skirt of his robe, as proof of what he might have done, and let him depart. After David, Solomon celebrated in his "song of songs" the vineyards of En-gedi, which, as the ruins still show, were planted all along the terraced side of the mountain. About 1000 years later the Jewish sect of the Essenes, in their progressive efforts to isolate themselves from all the impurities of life, chose at last as their retreat the absolute solitude of the caverns around the fountain of En-gedi. Four hundred years afterwards there was a large village on the coast below the fountain, the ruins of which yet remain.

ENGEL, CARL, author, b. in Thiedenweise, near Hanover, July 6, 1818; d. in London, Nov. 17, 1882. He studied the pianoforte under Hummel, and settled in London about 1844. He owned a large collection of rare musical instruments, many of which were given after his death to the South Kensington Museum, with which he had been connected for many years. His important books are: *The Music of the Most Ancient Nations* (London, 1864); and *An Introduction to the Study of National Music* (1866).

ENGEL, ERNST, statistician, b. in Dresden in 1821, studied at Freiberg, and afterwards at Paris. Subsequently called to the direction of the statistical bureau in Dresden, he superintended the publication of a number of important statistical works, and after the death of Dieterici, he became the head of the Prussian statistical bureau. His works are both numerous and valuable, including, among others, a comparison of German industries in 1861 and 1875, a work entitled *The Age of Steam*, and a treatise on the price of labor. His researches made clear the important law that, as the wages of workmen increased, a smaller proportional share of their income was expended upon the necessities of life, and a more than proportional share was applied to the gratification of the desire for luxury, social ambitions, and the like.

ENGELHARDT, JOH. GEORG VEIT, a learned German theologian, was b. 12th Nov., 1791, at Neustadt on the Aisch, and studied at Erlangen, where, in 1820, he was appointed extraordinary professor, and in 1823 ordinary professor of theology. He died 13th Sept., 1855. Patristic and mediæval dogmatics, and Neoplatonism, are the subjects which he has chiefly investigated. In 1820, he published at Erlangen a translation of the first *Ennead* of Plotinus; in 1823 appeared his translation of the writings ascribed to Dionysius the Areopagite. His *Kirchengeschichtlichen Abhandlungen* (Erl. 1832), *Auslegung des speculativen Theils des Evangeliums Johannis durch einen deutschen mystischen Theologen* (Erl. 1839), and his contribution to the history of the mystical theology, entitled *Richard von St. Victor und Johannes Ruysbroek* (Erl. 1838), are works of great value, and have thrown a new light on many important points. Very useful, too, especially on account of the richness of their special notices, are his *Handbuch der Kirchengeschichte* (Erl. 1834), and *Dogmengeschichte* (Neustadt, 1839). E., in the course of his life, wrote many learned dissertations in the *Journal of Historical Theology*, among which may be specified his *Ueber die Hesychiasten*, and *Ueber Erasmus Sacerius*.

ENGHIEN, LOUIS ANTOINE HENRI DE BOURBON, Duc d', only son of prince Henri Louis Joseph, Duc de Bourbon, was b. at Chantilly, 2d Aug., 1772. In 1789, he quitted France, and traveled through several countries of Europe. In 1792, he entered the corps of *émigrés* assembled by his grandfather, the prince of Condé, on the Rhine, and commanded the vanguard from 1796 until 1799. At the peace of Lunéville, in the year 1801, he went to reside at Ettenheim, an old château on the German side of the Rhine, not far from Strasburg, and within the territories of the duke of Baden. Here he married the princess Charlotte of Rohan Rochefort, and lived as a private citizen. When the conspiracy of the Bourbon princes, headed by Cadoudal, Pichegru, etc., against the life and authority of Bonaparte, was discovered at Paris, the latter chose to believe that the duc d'E. was privy to it, although there was not a tittle of evidence to prove this. Perhaps Bonaparte was afraid that the valor and humanity of the last descendant of the great Condé might one day prove dangerous to his power. Be that as it may, he unscrupulously resolved to seize the person of the duke. On the night of the 17th Mar., 1804, the neutral territory of Baden was violated, and the château of Ettenheim surrounded with a body of soldiers and gendarmes. The duke, at first, endeavored to defend himself; but the force was too great to be opposed, and he, with several friends and domestics, was captured, and carried prisoner to Strasburg, and immediately after to Vincennes. On the 20th of Mar., he was tried before a court-martial, consisting of

eight officers, and after an examination of five hours, was condemned to death. Half an hour later, the sentence was put into execution. So cruel and audaciously criminal an act has fixed a deep stigma on the character of Bonaparte. M. Dupin has published the records of the trial, and shown the illegality of the proceedings of the military commission. This illegality was publicly acknowledged by Gen. Hullin, the president of the court. After the restoration, the bones of the judicially murdered duke were taken up, and interred in the chapel of the castle at Vincennes.

ENGINEER AND ENGINEERING. Engineering, the business of the engineer, is the art of designing and superintending the execution of works of a constructive character, such as roads, railways, bridges, canals, harbors, docks, works for supplying water to towns, drainage and sewerage works, mining machinery, and the working of metals.

Engineering may be divided into several branches: mechanical, electrical, mining, civil and military. The two broadest branches are mechanical and civil engineering, and all of the other branches of engineering may be considered as special departments of one or the other of these two branches. The branches of engineering are constantly becoming more specialized. The military engineer is an officer in the service of government, whose duties are principally to construct fortifications, to make surveys for warlike purposes, to facilitate the passage of an army by the construction of roads and bridges; in short, to execute all engineering works of a military nature.

The civil engineering profession is subdivided into several sections, according to the special nature of the employment of its members. The railway engineer projects and superintends the execution of railways and all the works in connection with them, such as the alteration of roads and streams, the construction of viaducts, bridges, cuttings, and embankments. The hydraulic engineer constructs the works connected with the supply of water to towns, the filtering of water, its collection in reservoirs, and its distribution through a town or district; the irrigation and drainage of tracts of country; the protection of low lands from inundation, and the use of water as a motive-power. The dock and harbor engineer has the management of all works connected with the sea or navigable waters, such as the construction of piers, breakwaters, docks, harbors, and light-houses. The mechanical engineer is principally concerned in the manufacture of machinery, the working of metals, the construction of ships, steamers, cannon, and all the various structures in which the metals bear a prominent part. Then there is the mining engineer, who discovers minerals and manages mines; there are engineers who are specially engaged in the drainage of towns, and electrical engineers who are engaged in the designing and construction of plants for electric lighting, electric railways and electric power transmission.

In all engineering works, the *contractor* takes a very important part; he executes the works from the designs and under the direction and superintendence of the engineer, and on his good management the success of undertakings largely depends.

The engineering works of antiquity are both numerous and prominent, many of them remaining while all other traces of their constructors have been swept away. The most notable of the works belonging to very remote antiquity are the harbors of the Phenicians, the palaces and sewerage of Nimroud, and the pyramids of Egypt; next in order come the harbors of ancient Greece, the bridge of boats across the Dardanelles, made by Xerxes, to transport his immense army into Europe, and his canal across the isthmus of the peninsula of mount Athos. The buildings of ancient Rome next claim attention—its theaters, temples, baths, and aqueducts, some of which carried water from distances of more than 50 m. into Rome; its roads, bridges, and drainage-works vie in extent and magnificence with the most celebrated works of modern times.

From that period down to the commencement of the 18th c., the most extensive works executed are the canals, embankments, and other hydraulic constructions used by the Dutch for the purposes of inland navigation, and to protect their low lands from the sea; the canals of North Italy, the cathedrals and fortifications of mediæval Europe.

Civil engineering, as a distinct *profession*, may be said to have originated, in England, about the middle of the last century; since that time, the improvements in the steam-engine by James Watt, its subsequent application to the railway system by George Stephenson, and its use in navigation, have given a great impulse to commerce and civilization; which, in their turn, have created the necessity for the numerous and magnificent engineering works of modern times; such as the innumerable railways, roads, and canals that intersect this and foreign countries; the bridges, water-works, docks, harbors, and vessels that facilitate our commerce and increase our comfort and prosperity. Among the most remarkable of these works may be mentioned the tubular bridges of the St. Lawrence and Menai strait, the Niagara railway suspension bridge, and the electric telegraph system.

The education of those who would rise to eminence in the profession, must embrace a fair knowledge of pure mathematics and of the mixed sciences of natural philosophy, such as mechanics, hydrostatics, hydraulics, and optics. They should acquire a knowledge of the principles of projections, and should aim at being good draughtsmen and rapid and accurate arithmeticians.

In conclusion, it may be said that every day opens fresh fields to engineering science and labor; and that as the first beginnings of the art are lost in the obscurity of remote antiquity, so we see no termination to its usefulness and necessity.

The more important operations involved in engineering are treated of under such heads as AQUEDUCT; BRIDGE; CANAL; DYKE; EMBANKMENT; RAILWAYS; ROADS; SUSPENSION BRIDGES; TUBULAR BRIDGE; WATER-SUPPLY.

ENGINEERS, CORPS OF, organized in the United States in 1802, to consist of 1 col., 1 lieutenant-col., 2 majors, 4 captains, 4 first and second lieutenants and cadets, the whole number not to exceed 20, to be stationed at West Point and to constitute a military academy. In 1838 the corps was increased to 47 officers; and a corps of topographical engineers in addition, was organized. In 1846, sappers, miners, and pontoniers (bridge builders) were added. In 1861, at the beginning of the civil war, three additional companies were provided for, and one of topographical engineers was added. This company was disbanded in 1863, and its officers sent to the corps of engineers. In 1866 the battalion of engineers was organized from the companies already authorized, the station being at Willets Point, New York. The officers of the battalion, which comprises 500 enlisted men, are 1 lieutenant-col., 4 captains, 3 1st lieuts., and 7 2d lieuts. There are 34 sergeants, 34 corporals, 8 musicians, 210 privates 1st class, and 212 privates 2d class. The officers of the corps comprise 1 brig.-gen'l, 6 cols., 12 lieutenant-cols., 24 majors, 30 captains, 26 1st lieuts. and 10 2d lieuts. Their duties embrace reconnoitering and surveying for military purposes; the selection of sites and formation of plans and estimates for military defenses; the construction and repair of fortifications and their accessories of every description; the planning and superintending of defensive or offensive works of troops in the field; the examination of routes of communications for supplies and for military movements, and the construction of military roads and bridges; also the execution of river and harbor improvements, and such other duties as the President may order.

Until 1866 an engineer officer was always appointed as superintendent of the Military Academy at West Point, but since that year all branches of the service are admitted to their share of supervision. The first appointment of an engineer in the United States Navy was in 1836, a year before any similar appointment was made in the English navy, but the corps was not organized and incorporated in the navy register until 1843. The Secretary of the Navy wrote Captain M. C. Perry, in November, 1837, that the *Fulton* was allowed, as recommended by the Commissioners of the Navy, and approved by the navy department, 2 1st class engineers at \$800 per year each, 2 2d class engineers at \$500 per year each, 8 firemen at \$25 to \$30 per month, and 4 coal-heavers at \$15 per month. This was the germ of the engineer corps of the navy, which, by law of August 5, 1882, is to consist of 10 chief engineers, having the relative rank of captain in the navy, 15 with the relative rank of commander, and 45 with the relative rank of lieutenant-commander; 60 passed-assistant engineers, with the relative rank of lieutenant and lieutenant, junior grade; and 40 assistant-engineers of the relative rank of ensign. The present regulation for the appointment to the engineer corps requires that the class about entering upon the fourth year's course at the naval academy shall be divided into two portions, based upon the number of vacancies that have occurred the previous fiscal year in the line and marine corps combined and the engineer corps. Upon graduation the cadets are appointed to the grade of assistant engineer in a number corresponding to the total number of vacancies in that grade for the previous fiscal year, but whether vacancies exist or not at least two shall be appointed each year.

On board flagships, the chief engineer of the vessel is usually one of the general staff of the commander-in-chief, and in this position he exercises a general supervision over all the engineers of the fleet or squadron, makes quarterly inspections of machinery, and decides upon all ordinary repairs. Previous to the departure of any of the vessels on detached service he sees that they are provided with all that may be required in the engineer's department. He examines into the coal used by the squadron, reports upon its quality, and sees that it is properly stored at the depots, and that there is always a sufficient amount on hand for the probable use of the various vessels. The chief engineer has charge of the boilers and machinery, coal-bunkers and store-rooms, and keeps an account of the expenditure of coal and all other stores in his department. The assistants in the engineer's department carry into execution all orders received, and have care of the various portions of machinery, the boilers and their dependencies. They stand the watches in the engine-room when the vessel is under way under steam, and are responsible for the working of the machinery. The cadet engineers act as assistants, may be assigned to duty in charge of the engine-room and perform such other duties as may be assigned them by the chief engineer. The pay of a fleet engineer is \$4400 per year; the sea-pay of a chief engineer is \$2800 for the first five years after date of commission, \$3200 for the second five years, \$3500 for the third five years, \$3700 for the fourth five years, \$4200 after twenty years from the date of commission. The passed-assistants receive \$2000 for the first five years, \$2200 for the second five years, \$2450 for the third five years, and \$2700 for the fourth five years. The assistants receive \$1700 for the first five years, and \$1900 for the second five years. The cadet engineer receives \$950 per year.

ENGINEERS, IN THE UNITED STATES NAVY, are commissioned officers having charge of the machinery of steam vessels. They must have a thorough practical education in the construction and management of steam machinery. In military law, they are considered non-combatants.

ENGINEERS, THE ROYAL CORPS OF, forms one component portion of the army of the British empire. A similar corps exists in all regular armies. It is the scientific and constructive branch, intrusted with the making and defending of all military *works*, and the attack and conquest of similar works belonging to an enemy. It is true that civilians are often employed to construct the buildings themselves, at a stated price; but the military engineers make the plans, and are responsible to the country for their efficiency. At the present time, for instance, and for a number of years past, contractors are at work on fortifications at Portsmouth and in other parts of the kingdom, but on plans and under orders for which the engineer department of the government is responsible.

The royal engineers of the United Kingdom form one regiment or corps. The officers, in time of peace, are scattered all over the world. There is no half-pay, except on *permanent* retirement; and no unemployed list. They have much wear and tear of body and mind, and are considered entitled to a competent retiring allowance at an earlier age than other officers. Their regular pay corresponds to the active pay of other officers of the same rank; but they exclusively receive in addition *extra* pay, amounting to one-half their ordinary pay when on duty at home, and equaling their ordinary pay when employed abroad or in the London district. There is an establishment of engineers in each military command, to conduct and superintend all the military buildings and works. The entire force is under a particular department of the war-office, that of the inspector-gen. of fortifications. Until the year 1763, the duties of military engineers were discharged by officers taken from the regular army. In that year, however, the corps of engineers was formed, greatly to the advantage of the military service. In 1783, it was made a *royal* corps, and a distinctive uniform adopted.

ENGINEERS, IN THE ENGLISH NAVY, are the persons who attend to the machinery on board war-steamers. When such steamers were first adopted, men were obtained from private engineering establishments, or from merchant-steamers. In 1847 and 1848, many changes were made, to induce skillful and steady men to enter the service, and to maintain better discipline. The higher grades of them were raised from the rank of *warrant* officers to that of *commissioned* officers of a civil branch. There are now the grades of chief inspector of machinery afloat, inspector of machinery afloat, chief-engineer, engineer, and assistant-engineer, the last rank being subdivided into two classes. All these are commissioned officers, and are strictly examined before admission; their rank and promotion being by selection, and dependent on skill, character, and length of service. A chief-engineer is expected to be able to make notes in the log of every particular concerning the engines and boilers; to draw rough sketches of the machinery, with figured dimensions fit to work from; to understand and manage everything relating to engines, boilers, and furnaces; to understand practical mechanism generally, and the principles of the theoretical mechanism. The engineer and assistant-engineer are expected to possess, in a smaller degree, the same kinds of knowledge and skill. The pay varies from £511 for a chief inspector of machinery, down to £64 for a second-class assistant-engineer on harbor service.

ENGLAND, the southern and larger section of the island of Great Britain, and the most important member of the United Kingdom of Great Britain and Ireland. The geography of E. will be found under the head of GREAT BRITAIN, the present article being confined to a sketch of its history previous to the union with Scotland.

Of the inhabitants of E. before the Christian era, little is known. In some of the ancient geographers, there are a few scattered notices of a rude population, with whom a limited commerce in tin was carried on by the Phœnician merchants; and our information scarcely extends further. What is known of E. under the Roman occupation has already been embodied in the article BRITANNIA. An account of the country during the period intervening between the withdrawal of the Romans and the Norman conquest will be found in the article ANGLO-SAXONS.

When William of Normandy landed in E. to claim the crown which Edward the Confessor had bequeathed to him, he found that the people had raised to the throne Harold, the son of a popular nobleman. The resources of the Saxons, however, had been wasted in domestic conflicts before the attack of William; and the battle of Hastings (1066 A.D.) gave E. with comparative ease to the Normans. The next 20 years saw the conquest completed, and nearly all the large landed estates of the Saxons pass, on every pretext except the true one, into the hands of the Normans. William claimed, indeed, to rule as sovereign by hereditary right, but this made little difference to the fact of conquest. All the high offices in the state and in the church passed into the hands of a new race. The Danes alone could retain either property or dignity. For long, some of the Saxons maintained an unequal resistance, retiring to the forests as the outlaws whose adventures furnished the materials for those favorite popular legends, where, as in Robin Hood, the spoiling of the richer classes is depicted as one of the chief virtues. In the course of time, the Normans were absorbed among the Saxons, their very language disappearing, though leaving many traces. From this union arose the English people and the English language as they now exist.

The union of the Normans with the Saxons was not fully effected so long as the

Normans retained their foreign possessions. In king John's reign, the whole of these were lost, excepting Guienne and Poitou. Long wars under Henry III. and Edward I., and his famous son, the Black Prince, were continued, in the endeavor to regain the lost possessions; yet great victories like those of Cressy (1346 A.D.) and Poitiers (1356 A.D.) seemed to leave no result, for no sooner were the English armies withdrawn, than the population returned to their French allegiance. After Agincourt (1415 A.D.), Henry V., when he had forced himself to be acknowledged heir to the French throne, was virtually king of France, and held his court in Paris; yet, in a few years more, the rebellion of Joan of Arc came at a time when E. was weakened with the wars of the roses, and (1451 A.D.) nothing of foreign ground was left to this country excepting Calais.

To their efforts to conquer France, the Norman kings added others. Henry II. conquered Ireland (1171 A.D.), Edward I. conquered Wales (1285 A.D.), and had almost added Scotland to his dominions. The bravery of Wallace and Bruce defeated the armies of Edward II., his successor; and though the idea of the conquest of Scotland was always a favorite one, an opportunity for attempting it on a great scale never again presented itself.

The great struggles of the successors of William were with the ecclesiastics and with the barons. Sometimes in these the popular sympathies were with, and sometimes against the crown. The conqueror himself and his immediate successors had no difficulty in maintaining the superiority of the courts of justice over the ecclesiastics; but even a sovereign so bold and skillful as Henry II. was forced, after the outcry occasioned by the murder of Thomas à Becket (1170 A.D.), to yield the point. The right to nominate the higher ecclesiastics was also secured by the popes. The degradation of the English monarchy was at its lowest when king John consented (1213 A.D.) to hold the crown as a gift from Rome. The weaknesses of this monarch had good as well as evil results, for from him the barons won their great charter (1215 A.D.). From Henry II. something similar had already been gained; but it was the Magna Charta of John which firmly established two great English principles—that no man should suffer arbitrary imprisonment, and that no tax should be imposed without the consent of the council of the nation. Under Edward I., the famous statute that no manner of tax should be imposed without the common consent of the bishops, barons, and burgesses of the realm, was passed (1296 A.D.); and before the time of Henry VII., the foundations of parliamentary government had been laid.

The union of the houses of York and Lancaster under Henry VII. begins a new period in English history. Part of his reign was disturbed by Perkin Warbeck and other pretenders to the throne, in support of whose claims the turbulent nobles found vent for their restlessness. But the greater part of his long reign was distinguished from preceding reigns as a time of peace and economy. During it, men's minds ripened for the great events of the next reign. Henry VIII. succeeded, under the most favorable auspices. He found the alliance of his now important country courted by both of his great contemporaries, Francis I. and Charles V. But the interest of the foreign complications of the reign merges in the struggle between the courts of E. and of Rome. The origin of the contest was the divorce which Henry desired to have from Catharine of Aragon, his brother's widow, to whom he had been married by papal license. Cranmer and the English church pronounced the marriage to be null, but a formal decree of divorce by the head of the church was then thought necessary in Catholic Europe. Pope Clement and the consistory, influenced by Spanish counsels, delayed, by every possible means, the decision of the question. E., however, was ready enough to support Henry. Wickliffe and his adherents had done not a little to shake the attachment of the nation to a foreign spiritual authority, by preaching doctrines which dispensed with the necessity for it. A parliament met, when the commons took the significant step of presenting a long memorial of complaints against the church. The pope, still showing no signs of yielding, bills followed, declaring the king the head of the church; rendering the inferior clergy amenable to the civil courts; abolishing the payment of the first year's fruits of ecclesiastical livings to Rome; and perhaps a more important thing than any of these, declaring that no convocation should meet unless the king should summon it, and that no ecclesiastical canons should have force except with the king's consent. To these measures, the pope replied by refusing the divorce, and excommunicating the king (1533 A.D.). The breach thus became irreparable.

A new act was passed giving to the magistrates the power of judging in questions of heresy. The next step was the suppression of nearly 400 of the smaller monasteries. The subsidence of an insignificant popular reaction, incited by the lower clergy, was followed by the suppression of the great abbeys. All these changes, however, touched only matters of church government. On matters of faith, Henry and his parliaments were as orthodox as the most conservative could wish. They embodied the leading doctrines of Romanism, disputed by the Protestants, in an act of parliament, known among the people as "the bloody six articles," and enforced conformity under severe penalties.

Henry was succeeded by Edward VI. His reign was marked by the general progress which the reformation now made from questions of government to questions of doctrine. More thoroughly than ever the power of the clergy was sapped. The Book of

Common Prayer (1548 A.D.) deprived them of the mysterious authority which the use of a foreign language in worship gave them in the eyes of the people, and the 42 articles of the church of E. (1552 A.D.), the foundation of the present 39, denied, among other things, their power to work miracles in the elevation of the mass.

The next reign saw the inevitable reaction. The superstitions of the populace had been too rudely handled, and—as often happens before a crisis—there came a period of physical suffering. The conversion of cornfields into sheep-walks, induced by the high value of wool as an article of export, had thrown many out of employment; and the country was, moreover, infested with the crowd of vagrants whom the monasteries had been wont to maintain. The popular dissatisfaction coupled these things with the reformation. Thus the opportunity was prepared for the atrocities of the reign of Mary. The queen herself was interested, by her mother's honor and her own, to uphold the Romanist faith; and her gloomy temper, aggravated by her unhappy childless marriage, believed that it did true service to God when it gave the rein to the bigotry of Pole and Bonner. In her first parliament (1553 A.D.), the whole legislation of Edward VI. was repealed, leaving the church of E. one in ceremonial and doctrine with the church of Rome. Another parliament (1555 A.D.) repealed the legislation of Henry VIII., thus re-establishing the papal supremacy. Everything that the reformers had done was thus undone. Still the adherents of the reformation were numerous, and when legislation failed to convert them, the fires of Smithfield were tried. Hooper, bishop of Gloucester, was one of the first to suffer. Latimer, Ridley, Cranmer, followed, and the number who perished is not less than 300 by fire, and 100 by torture and the cruelties of confinement. Nothing more was wanted to turn the popular mind at once and forever from the church of Rome.

The accession of the Protestant princess Elizabeth came as a relief to the whole nation. The Romanists themselves were weary of the policy which made E. the tool of Spain, and were sickened with the cruelties which had been enacted. Elizabeth began by releasing from prison all confined on charges of heresy. Parliament followed (1559 A.D.) with acts restoring the royal supremacy over the church, and returning in general to the legislation of Edward VI. The prayer-book and the 39 articles were adjusted as they still exist. Fortunately for the country, the ministry of Elizabeth, guided by the able hand of Cecil, was one of peace. No opportunity was lost of aiding the Protestant cause throughout Europe; but Elizabeth had almost no open wars, and her long reign was disturbed by almost no domestic collisions. The mistake committed in detaining the queen of Scotland in an English prison, gave a constant incitement to disaffection among the adherents of the old faith, but no serious consequences ensued. Towards the close of the reign, Protestant and Catholic were alike patriotic in repelling the Armada (1588 A.D.). On the death of Elizabeth, the crowns of E. and Scotland were united.

The reign of James VI does not present much that is remarkable. The plot, for which sir Walter Raleigh suffered long afterwards, and the Gunpowder plot—the insignificant proportions of which were so magnified for factious purposes—disturbed the earlier years; and the close of the reign found the nation engaged in an unfortunate war to assist the king's son-in-law, Frederick, elector of Bohemia, against the emperor Ferdinand II. of Germany. But for the greater portion of the 23 years of the reign there was neither foreign nor domestic war. These years the king occupied industriously in rendering monarchy odious and contemptible. He lavished money upon unworthy favorites, and to supply his extravagance, openly sold the dignities of the peerage and the other honors of the state. His personal demeanor was vain, weak, and ridiculous; but in contrast with the insignificance of his talents was his extravagant conception of the extent of his royal prerogative. His conduct occasioned great discontent in parliament, and but for his timidity might have led to more serious consequences.

The misfortunes of Charles I. were the legitimate result of the principles of his father. Charles committed the mistake of repeating, in the 17th c., acts which the Plantagenet sovereigns had done with impunity in the 14th and 15th. One of his first acts was to exact a benevolence to carry on the war. Had he been successful, this might have been overlooked, but when the bad management of the duke of Buckingham lost the fleet off Rochelle, the indignation of the commons was without bounds. In place of taking measures to allay this feeling, the king dissolved the parliament, and resolved to govern without calling another. In 1630, he concluded peace, and for the next seven years, in council with Strafford and Laud, he carried on the government. Taxes were raised as before without parliamentary authority; and when the taxes failed, money was raised by selling to the Roman Catholics immunities from the penal laws against their worship.

Nevertheless, there were limits to these methods of raising money; and in 1637, when the king found himself involved in a war with Scotland, in consequence of his endeavor to introduce a liturgy there, he was compelled to call a parliament. The commons refused supplies, and were again dissolved. In 1640, the king once more summoned a parliament. He found the temper of the houses more indomitable than ever. In place of voting him supplies, they impeached his minister Strafford, and condemned him to death. The commons then presented a grand remonstrance to the king, embodying all the grievances the nation had suffered since the death of Elizabeth. Matters proceeded from bad to worse, till an open rupture came, and an appeal was made to arms. In Aug.,

1642, the king erected his standard at Nottingham, while the rebels took arms under the earl of Essex. The first conflict was at Edgehill, where the loss on both sides was severe and nearly equal. The fortune of war continued to vary, till at Marston Moor it turned against Charles, and at Naseby, in June, 1645, he was finally defeated. He was executed on 30th Jan., 1649.

The government for the next four years was conducted by parliament. Meanwhile, Cromwell was rising into distinction, and power gradually fell from the hands of parliament into those of the military. In 1653, Cromwell had himself proclaimed "Protector." He was now absolute monarch. He governed with a firm hand, and never was E. more respected abroad than during his time. In 1654, he concluded peace with Holland, and employed the gallant Admiral Blake in an expedition against the Spaniards, which ended brilliantly for the English navy. But the nation grew as discontented with the government of Cromwell as it had been with that of Charles. After the death of the protector in 1658, and a short interval during which his son Richard held the office, parliament received with acclamations a proposal from Charles II. to return. In May, 1660, the populace clamored with delight on the royal entry to London of him who, a few years before, had fled from Worcester for his life.

While Clarendon was minister, the government of Charles II. was well conducted. A war with Holland was brought to a successful ending in the conquest of New York. On Clarendon's resignation, the government passed into the hands of the ministry known as the Cabal. They were as profligate and as careless as the king himself. A succession of cruelties against the Catholics, for which the pretended revelations of Titus Oates and his imitators furnished the excuse, betokened rather the wanton temper of the sovereign and the nation, than any zeal for the Protestant religion. The only act which reflects much credit on any portion of the reign was the passing, in 1679, of the *habeas corpus* act, designed more effectually to protect the liberty of the person. Strong efforts were made in parliament after that to pass the exclusion bill, the object of which was to exclude the duke of York, as a Roman Catholic, from the succession. To the great satisfaction of the king, parliament rejected the bill. In 1681, parliament was dissolved, and Charles II. never called another.

After this there was a change for the worse in the character of the government; from being wantonly indifferent, it became sullenly mischievous. Presbyterians and non-conformists were excluded from all offices. Among other arbitrary acts, may be mentioned the recall of their charters from London and many of the other principal cities, which were only restored, with diminished privileges, on payment of heavy fines. Conduct such as this made men more than ever afraid of the succession of the king's brother. A conspiracy to secure the succession to the duke of Monmouth, an illegitimate son of the king, was formed. Lord Howard betrayed the conspiracy, and among others who suffered death for it were lord Russell and Algernon Sidney.

When the king died, in 1685, James II. succeeded amid universal dissatisfaction. Monmouth's attempt to seize the throne, however, was mismanaged, and failed. The punishment of those who had aided his rising formed an occasion for the perpetration of great cruelties by Jeffreys, then chief-justice of England. In the meantime, nothing could be fairer than the king's language. He issued a declaration in favor of general toleration, and announced that the penal laws against Catholics were no longer to be enforced. A second declaration to the same effect was issued, but he went further, and added to it an order that the clergy should read it in all churches. The archbishop of Canterbury and six bishops presented an address to the throne, humbly setting forth that their duty to maintain the Protestant establishment would not permit them to give obedience to the royal mandate. For this they were indicted as guilty of sedition. The trial of the bishops (1688 A.D.) was the turning-point of James's career. It created immense excitement, and when the jury returned a verdict of not guilty, even the soldiers joined in the tumultuous rejoicings.

William, prince of Orange, who had married Mary, the eldest daughter of the king, had long been intriguing with the malcontents. He now landed in E. with a small body of troops. The soldiers, the leading nobles, even the king's own children, joining the prince, the king fled to France. Parliament then settled the crown jointly on William and Mary for life. James, with the assistance of Louis XIV., made one effort to regain his throne. He landed in Ireland, where the lord lieutenant, Tyrconnel, was devoted to his cause, and managed to raise an army. William defeated him at the battle of the Boyne; and the contest was soon after this terminated by the second flight of James to France. So easily was the great revolution of 1688 effected.

The domestic government of William was marked by his efforts to introduce a general toleration; but of his foreign administration, which led the country into costly wars, it is hardly possible to speak in very favorable terms. To reduce the threatening power of France, E., in alliance with Holland and Germany, embarked in a protracted contest. Its termination at the peace of Ryswick, in 1697, brought to E. nothing beyond an increase of reputation. William died in 1702.

Under queen Anne, the war with France was renewed, and the duke of Marlborough's splendid victories of Oudenarde, Blenheim, and Ramilies were achieved. With these the history of E. as a separate state closes. In 1707, the long-wished-for union with Scotland was accomplished; and after that, Great Britain, united under one legislature,

as well as under one crown, has a common interest among nations, and therefore a common history. For the history of the United Kingdom, see the article GREAT BRITAIN.

A table of the English sovereigns is appended, beginning with Alfred, and continued, for convenience' sake, to the present time:

| | | Began to Years of | | | | Began to Years of | |

ENGLAND, CHURCH OF. A brief sketch of the origin and early history, as well as an outline of the doctrines and form of government of this church, will be found under the head **ANGLO CATHOLIC CHURCH**. See also the articles **AUGUSTINE** and **DUNSTAN**. Up to the time of the reformation, ecclesiastical affairs would be more properly described as the history of the church *in* England; from that period the church *of* England dates her existence. She, however, retains so much of antiquity, and her institutions, laws, and formularies are so interwoven with the history of the past, that it would be impossible to have any correct or connected view of them, and of her *connection with the state*, her characteristic feature, without at least glancing rapidly over the leading events between the conquest and the reign of Henry VIII. During the three centuries from the Norman conquest (1066) to the preaching of Wickliffe (1356), her history can be regarded only as a continual struggle between the ecclesiastical and civil power, and there would be little else to describe than the methods by which the miter triumphed over the crown, and the crown invaded the rights and property of the church. In the time of William I., nearly half the country was in the hands of spiritual persons. He ejected the English clergy, and supplanted them with Normans; and although he was possessed of full power over the church, yet in his reign were sown the seeds of future papal encroachments. Papal legates were then first introduced into England, and the ecclesiastical courts separated from the civil. From this time, the increased influence of Rome may be traced to the defective titles, the usurpations, and the violent conduct of the kings. Thus, the defective title of Henry I. made him seek popularity by recalling the primate Anselm, who had incurred the displeasure of his brother William, and had fled the country. Anselm was devoted to the pope, who had espoused his quarrel, and refused to do homage to the king for the temporalities of his see, till at length Henry found himself obliged to surrender the right of *investiture*. Thus, too, Stephen's usurpation opened the way for further encroachments; and Henry II., who found the power of Rome greatly augmented, helped to extend it further, by accepting a grant of Ireland from the pope. Then followed the opposition of Thomas à Becket, which arose out of the question of the punishment of ecclesiastics by the civil power. For the moment, it seemed that the quarrel was healed by the *constitutions* agreed on at Clarendon (q.v.), but it broke out more violently than ever. The pope discharged Becket from his oath, and condemned the constitutions. Becket had fled from the kingdom; and his subsequent return, murder, and canonization, all tended to strengthen the authority of the church. It was not, however, till the reign of John, when England was laid under an interdict, and the king resigned his crown to the pope, that the papal encroachments rose to their height; and the weak reign of Henry III., which followed, did nothing to abate them. Edward I. gave a check to the power of the clergy, subjoined them to taxation, and passed the statute of Mortmain (1279), which prohibited

the transfer of land without the king's consent. There is little to be said as to innovations in doctrine during these three centuries; but it may be noted, that about the middle of this period, viz., 1213, the council of St. John Lateran declared transubstantiation, or the bodily presence of Christ in the consecrated elements, to be a tenet of the church.

It was in 1356 that a new period commenced. Wickliffe then published his first work, entitled *The Last Age of the Church*, directed against the covetousness of the church of Rome. His doctrines correspond in many points with those now taught by the church of England, but he differed from her in regard to the necessity of episcopacy, which he rejected; he also believed in purgatory, and enjoined prayers for the dead. His chief objects of attack were the papal indulgences, and the doctrine of transubstantiation. It has been observed concerning the condemnation at Oxford of Wickliffe's opinions with respect to the latter, that "this was the first plenary determination of the church of England in the case, so that this doctrine, which brought so many to the stake, had but with us 140 years' prescription before the times of Martin Luther." In a limited sense, he upheld the efficacy of the seven sacraments. Wickliffe had a large body of followers. They were called *Lollards*, probably from a German word, *lullen*, to sing with a low voice. The storm of persecution which he escaped by death, fell upon them. Henry IV. thought it necessary to fortify his usurped position by assisting the bishops against the Lollards; and from this time to the reformation, there was an uninterrupted succession of confessors and martyrs. Sir John Oldcastle, lord Cobham, was the most illustrious of these sufferers. Fox gives a detailed account of nearly 20 individuals burned for heresy between the death of lord Cobham and 1509, when Henry VIII. ascended the throne. To some extent, the blood of these martyrs was the seed of the Reformed church; but we must not overlook the "hidden seed" which was growing secretly, from the time that Wickliffe gave to his countrymen a translation of the Scriptures in their own tongue. The progress of learning, and especially the study of Greek, led to a better understanding of the sacred books, whilst the invention of printing (1442) caused a wider circulation of them.

The above causes, however, would probably have proved insufficient to produce the great change which was now impending, had not Henry VIII.'s divorce from Catharine of Spain led to a quarrel between him and the pope, which ended in the total abolition of the papal authority within the kingdom. Then began the REFORMATION in earnest. For the details of that great event, consult the article under that head, and the lives of such men as Wolsey, sir Thomas More, Fisher, Clement, Luther, Cromwell, Cranmer, Latimer, and Ridley, etc. From this period may be dated the existence of the church of England as a separate body, and her final separation from Rome. For the opinions of the church in Henry's reign, two important books which were then published should be consulted—viz., the *Bishop's Book*, or the *Godly and Pious Institution of a Christian Man*, and the *King's Book*, which was a republication of the same in a more perfect form in 1543, and called *The Necessary Erudition for any Christian Man*, and was called the *King's* book because put forth by royal authority. A book of *Articles devised by the Kinges Highnes Majestie to stablyshe Christen Unitie*, should also be consulted. It has been stated in the article ANGLO-CATHOLIC CHURCH, that the reformation in doctrine did not make much progress in Henry's reign; from these books, it will be seen that it was rather retrograde. The monks, too, who were dispossessed at the dissolution of the monasteries, were dispersed amongst local cures, and kept alive the old opinions, and the lower orders were not as yet favorable to the new doctrines. Cranmer was the leader and presiding genius of the reformed opinions; and the youth of Edward VI. left the king pliant in the hands of the archbishop. The book of Homilies, put forth in 1540, the New Communion Service and Catechism in 1548, the first Book of Common Prayer in 1549, and the Forty-two Articles in 1553, all bear the impress of his hand, and it was these which advanced and fixed the doctrines of the reformation. Nor was the temporal authority idle on the same side—Bonner and Gardiner were committed to prison, and both were deprived of their bishoprics. In fact, the way in which all the institutions of the church of England were established in Edward VI.'s reign by the help of the civil magistrate, have brought upon her the charge of Erastianism. The civil power had just delivered her from a foreign tyranny; and when the weak health of the young king, the known sentiments of his successor, Mary, the ignorance of the common people, and the interested views of the old clergy, are considered, it cannot be a matter of surprise, still less of blame, that the same arm was relied upon for the establishment of the new forms of religion.

Although Mary promised at her accession that she would put constraint on no person's religion, her promise was not kept. Bonner and Gardiner were restored; the Book of Common Prayer and Catechism were declared heretical; the kingdom was reconciled to the see of Rome; a persecution of the chief reformers commenced—Rogers was burned at Smithfield, Hooper at Gloucester, Saunders at Coventry, Taylor at Hadley. The prisons were filled with "heretics;" many fled beyond sea; some purchased safety by an outward conformity. Cranmer, Latimer, and Ridley perished in the flames at Oxford. Cardinal Pole was made primate. One benefit was conferred on the church by Mary—she surrendered all the church lands, as well as the first fruits and tenths, which had been seized by Henry. At last the death of Mary, with which that of the

cardinal was all but simultaneous, delivered the church from its oppressors. The passing of the *act of uniformity* in the first year of Elizabeth's reign, restored the common prayer-book to general use, and enjoined the same dresses as were in use at the time of the first prayer-book of Edward VI. All the bishops except one, Kitchin of Llandaff, refused to take the oath of uniformity, and were ejected from their sees to the number of 14 (the eleven remaining sees were vacant by deaths), and 175 other beneficed clergy were deprived for the same cause—no very considerable number, when it is remembered that there were then 9,400 benefices in England. There was some difficulty in filling up the vacant bishoprics, and perhaps some slight informalities. Matthew Parker was made archbishop of Canterbury. For the refutation of the fable of the NAG'S-HEAD CONSECRATION, see the article under that head. In 1562, the Thirty-nine Articles were finally reviewed and subscribed. These, with the Book of Common Prayer, are the tests of orthodoxy in the church of England.

But what was done to satisfy the scruples of Protestant non-conformists? An attempt in this direction was made in the reign of James I. at the Hampton Court conference (q.v.). The result was another review of the common prayer-book; and this, with the new translation of the Bible, and the passing of the canons of 1604, were the principal ecclesiastical events of James' reign. These canons received the sanction of the crown, but not that of parliament; they are not, therefore, binding on the laity, but they are still binding on the clergy to some extent, and they regulate the practice of the ecclesiastical courts, and are the only rule, on some points, to which the bishops and clergy can appeal. See the articles LAUD, and SCOTLAND, CHURCH OF, for the events of Charles I.'s reign. The great rebellion overthrew both church and state. The bishops were declared "delinquents," robbed of their property, and abolished; and the clergy were ejected from their benefices. Laud was put to death in 1645. The church of England had no corporate existence during this interval. With the restoration of the monarchy, 1660, came the restoration of the church. The reaction from Puritanism to Prelacy was complete. Attempts were made, but with small success, to win over the Puritan leaders; bishoprics were offered to Baxter, Calamy, and Reynolds; but the last only accepted. The Savoy conference (q.v.) was an unsuccessful, perhaps insincere attempt to comprehend the non-conformists in the established church. But the demands of the Presbyterians were most immoderate. Baxter went so far as to propose the substitution of an entirely new book of his own composition, in the place of the common prayer-book. After the failure of the Savoy conference, this was once more reviewed; and a new act of uniformity in 1662 made its use, as it now stands, compulsory in all the churches.

The church of England passed through one more critical period before reaching that tranquillity in which, for upwards of a century, she slumbered too securely. In 1687, James II. published the famous declaration of indulgence, which filled up the measure of popular discontent, and finally cost him his crown. Although by this declaration, which was perfectly illegal, liberty of conscience was permitted to all his subjects, it was clearly understood that the liberty was intended only for the papists. The nonconformists refused to accept the treacherous boon. Eighteen bishops out of twenty-five refused to publish the declaration, as ordered, in their dioceses. Seven of them—Sancreft, Lloyd, Ken, Turner, Lake, White, and Trelawney—drew up a remonstrance to the king; they were summoned before the privy council, and sent to the Tower. The whole city was in commotion; and great was the rejoicing when, on being brought to trial in Westminster hall, they were acquitted. On the 5th of Nov. following, 1688, the prince of Orange landed in England. It is worthy of remark, that out of these seven bishops three refused to swear allegiance to him, and were joined by a considerable number of the clergy; these were called Non-jurors. In the first year of William and Mary's reign, the toleration act was passed, and dissent ceased to be illegal. Another attempt was made to comprehend the nonconformists in the church, but the lower house of convocation was in no tolerant mood, and the attempt failed, but chiefly in consequence of the disturbances in Scotland. In 1717, convocation was dissolved. After slumbering for nearly 140 years, it was once more called into life and action in the province of Canterbury in 1853, under the ministry of the earl of Aberdeen, and a few years later the convocation of York also took advantage of the liberty accorded by the crown on the advice of this government. See CONVOCATION.

That the church of England, after fighting for its very existence against popery on the one hand, and against Puritanism on the other, should have subsided into inactivity during the dull reigns of the Georges, is less a matter of surprise than of regret. The peaceful enjoyment of her temporalities in a dull, irreligious, not to say infidel age, may easily account for, though it cannot excuse, her idleness. But that in the rise of John Wesley, 1730, she should have failed to see a grand opportunity for herself, is a matter of both surprise and regret; she, however, let it pass; perhaps she can hardly hope that such another will ever again present itself. The utmost that can be hoped is, that she has seen her error. The next important event in the history of the church is the act of union, which came into effect on the 1st of Jan., 1801, and united the churches of England and Ireland in all matters of doctrine, worship, and discipline. The reformation had made some progress in Ireland under Edward VI. Five Protestant bishops were appointed in 1550, and the English Bible and liturgy were introduced in 1551; but

from a variety of causes, the reformed doctrines have never found much acceptance with the native population; and although a Protestant church was established by law, it was and is the church of the minority (see IRELAND). In 1635, the English articles were received; and in 1662, the English book of common prayer was adopted by convocation. Before the political union of the countries, the two churches were in full communion. By an act of the imperial parliament in 1833, ten of the Irish bishoprics were suppressed, and the funds thus obtained were applied to the augmentation of small livings and the building and repair of churches. There are now twelve Irish bishops. But in 1869, the Irish church was disestablished and disendowed; and this branch of the Anglican community now stands in much the same relation to the church of England as does the Episcopal church in Scotland.

In later times, three great controversies have shaken the English church, which have led to some great reforms, some internal divisions, and the secession of some members to Rome, of a few to the ranks of dissent. These were the Tractarian, the Gorham, and the Essays-and-Reviews controversies. The former was occasioned by some tracts which began to be published at Oxford in 1833, the object of which was to revive something of the spirit of Catholic antiquity, and reform the abuses and slovenly practices which had crept into every part of the church system. See TRACTARIANISM. The Gorham controversy (q.v.) related to the doctrine of baptismal regeneration. The Tractarians are accused of Romanizing tendencies; and their views, when carried to extremes, undoubtedly lead in that direction, as is proved by the numerous secessions to that church. With the extreme low church party, episcopacy is rather an expedient than a necessary form of church government. They think but little of the efficacy of sacraments, and deny that regeneration necessarily takes place in infant baptism. Justification by faith, the atonement of the cross, and the Calvinistic doctrines on election, are their leading topics in preaching. Charles Simeon (q.v.) and Henry Venn (q.v.) were leaders in this party.

The Essays-and-Reviews controversy (so called from a book thus named) concerned what are called BROAD CHURCH views, which are attributed to men of the Arnold school, and the followers of Mr. Maurice (q.v.). Those who hold them can scarcely be called a party, and are, indeed, unwilling to be so considered; but if their position must be defined, they might be described as a party between, and somewhat antagonistic to, both the high and low church parties. The high church party insist on the authority of the church and priesthood, the efficacy of sacraments when rightly received, and the necessity of apostolical succession in the matter of orders, and in their general teaching they take the prayer-book as the exponent of Scripture. They are scrupulous in observing the rubrics, and have done much to revive the practice of daily prayer in the churches, and the observance of the festivals. Order, unity, antiquity, and catholicity are what they profess to have in view. See RITUALISM.

There are at present, in round numbers, 13,000 benefices in England and Wales, of which a large number are new districts, which are being continually formed out of the old large and overpopulous parishes. These districts are called perpetual curacies, or incumbencies, and for the most part are but very slenderly endowed. The old benefices are either rectories, where the incumbent receives the *great* or corn tithes, or vicarages, where he receives the small tithe only. The great tithes had anciently been bestowed upon the neighboring monasteries, who undertook the cure of the souls and appointed vicars for the purpose, who lived on the small tithes and the offerings of the people. At the dissolution of the monasteries, many of the great tithes were given to laymen, and laymen now extensively hold them, and some to endowed colleges. The endowments were all by private beneficence, and there is no tenure so ancient as that by which the parish church holds her property. The aggregate amount was ascertained by the commission appointed in 1830 to be as follows: Bishops, £181,631; deans and chapters, £360,095; parochial clergy, £3,251,159; total annual revenue, £3,792,885. In 1891 the revenues of the church, from endowments in tithes, land and offerings, were estimated at £8,000,000. The church rates, amounting to £500,000 annually, were no part of the minister's endowment; they were exclusively devoted to the repairs of the church fabric, and the warming, lighting, cleaning, etc., of the church; and were under the exclusive control of the church-wardens. Of these there are two in each parish, one generally nominated by the minister, the other elected by the parishioners. The payment of church rates is no longer compulsory. The church accommodation (1896) was represented by 6,000,000 sittings.

The church of England has three orders of clergy—bishops, priests, and deacons. Generally, a degree at one of the English universities, or at Dublin, is required in a candidate for orders; but in Wales and some of the more populous districts, this condition is dispensed with. In England and Wales there are two archbishops (Canterbury and York) and 33 bishops; besides 2 archbishops and 11 bishops in Ireland. There are also 17 suffragan and 5 assistant bishops, 31 deans, 91 archdeacons, 810 rural deans, about 14,200 beneficed clergy, and about 7,400 curates. See GREAT BRITAIN.

The patronage of the church is in a great variety of hands—in the crown, the bishops, the nobles, and the gentry, and incorporate bodies such as colleges and cathedrals. Advowsons and next presentations may be sold as property, but a presentation may not be sold when a living is vacant. A clergyman is "presented" to his living by the

patron; he is admitted and inducted by the bishop or his appointee; he must "read himself in," i.e., he must read the Thirty-nine Articles after the morning or evening prayer within two months after induction. The bishop may refuse institution on the ground of false doctrine or immorality; but an appeal lies to the Archies court and the head court of appeal.

The Episcopal church in Scotland is not, politically speaking, in union with that of England. But an act of parliament, passed in 1864, has taken away many restrictions imposed on Scottish Episcopalians after the battle of Culloden; and clergy ordained by Scotch bishops may now, under some slight restrictions, be presented to benefices in England. Events connected with the colonies have also drawn these two communions into closer alliance; and some bishops, selected by English authorities for foreign parts, have been consecrated in Scotland.

The above sketch has been largely drawn from Short's excellent *History of the Church of England*; see also Marsden's able *Dictionary of Christian Churches and Sects*, and Hardwick; also Fuller's *Church History*, Collier, Strype, Mosheim, Burnet, and Clarendon. Among the great divines whose works should be consulted for further information regarding the views of the church, may be named Barrow, Pearson, Hooker, Jeremy Taylor, Lightfoot, Hammond, Sancroft, South, Tillotson, bishop Butler, Atterbury, Bull, Sherlock, and others. See EPISCOPACY; ARCHBISHOP, BISHOP; DEAN.

ENGLAND, FREE CHURCH OF. See REFORMED EPISCOPAL CHURCH.

ENGLANTE, in heraldry, is bearing acorns or other similar glands.

EN'GLESHERY, EN'GLESBURY, i.e., being an Englishman. The presentment of Engleshery is thus explained, Hale's *Pl. of Crown*, p. 446: "Anciently, there was a law introduced by Canutus the Dane, that if any man were slain in the fields, and the manslaughter were unknown, and could not be taken, the township where he was slain should be amerced to 66 marks; and if it were not sufficient to pay it, the 100 should be charged, unless it could be made appear before the coroner, upon the view of the body, that the party slain was an *Englishman*; and this making it appear was various according to the custom of several places, but most ordinarily it was by the testimony of two males of the part of the father of him that was slain, and by two females of the part of his mother." William the Conqueror continued this law. Presentment of E. was taken away 21 Edw. III. st. 1. c. 4.

ENGLEWOOD, a city (incorporated 1896), in Bergen co., N. J., 15 m. n. of New York, on the West Shore and the Northern New Jersey railroads. It is occupied chiefly by the families of men who do business in New York and has large boarding houses, several churches, hospital, public library, national bank, electric railroad, weekly newspapers, and several high grade schools. It is noted for fine scenery and cultivated society. Pop. '90, 4785.

ENGLISH, forms the first part of several geographical names.—1. English cove is a bay of the Pacific ocean, on the s.w. coast of the island of Neu-Mecklenburg (formerly New Ireland) in the Bismarck Archipelago.—2. English harbor, on the s. coast of Antigua, is one of the best havens in the West Indies. It is situated in lat. 17° 3' n., and long. 61° 45' west.—3. English harbor is on the Pacific shore of Costa Rica, in Central America, lying in lat. 8° 50' n., and long. 83° 55' west.—4. English river is an estuary on the w. side of Delagoa bay, an inlet of the Indian ocean, in Africa. It is about lat. 25° 58' s., and long. 32° 36' east.—5. English river, otherwise known as Mississippi or Churchill, enters Hudson's bay from the w. at fort Churchill, about lat. 59° n., and long. 94° w., after an estimated course of 800 miles.

ENGLISH, GEORGE BETHUNE, 1787-1828; b. Mass.; graduated at Harvard, and was a member of the Boston bar, but finally studied divinity. He published *The Grounds of Christianity Examined*, a work favoring Jewish views. After editing a paper in the west, he became a lieutenant of marines, and went on service in the Mediterranean, resigned his commission, became a Mohammedan, joined the army of Ismail Pasha in 1820, and served in the artillery in the expedition against Sennaar. He was subsequently agent for the United States government in the Levant, returning home in 1827. He published *Narrative of the Expedition to Dongola and Sennaar*.

ENGLISH, JAMES EDWARD, b. New Haven, Conn., 1812; was a member of the Conn. house of rep., 1855; and of the state senate, 1856-58; was elected as a democrat from Conn. to the XXXVIIth, and re-elected to the XXXVIIIth congress; was elected gov. of Conn., 1867, defeating Joseph R. Hawley; re-elected, 1868, defeating Marshall Jewell. E. was for the third time elected gov. in 1880; and was appointed U. S. senator from Conn., 1875, to fill the vacancy caused by the death of Orris S. Ferry. He d. in 1890.

ENGLISH, THOMAS DUNN, b. Philadelphia, 1819; studied medicine and law, but soon devoted his whole attention to literature, editing newspapers and magazines, and writing novels, dramas, poems, etc. His song of *Ben Bolt* is widely known. He was a democratic member of congress from New Jersey in 1891-5, and composed *Old Glory*, a patriotic march song, in 1895.

ENGLISH, WILLIAM HAYDEN, b. Ind., 1822. He studied law, and in 1843 was chosen clerk of the Indiana house of representatives. In 1851, he was made speaker of the

legislature, and in 1852 was elected to congress, holding his seat till 1860, when he retired from active political life. His chief title to distinction was his nomination for vice-president of the United States by the democratic national convention, in 1880, on the ticket with Gen. Winfield S. Hancock for president. He d. in 1896.

ENGLISH or BRITISH CHANNEL (*La Manche* or the *Sleeve* of the French, and the *Oceanus Britannicus* of the Romans) is the narrow sea which separates England and France, having on the n. the English counties of Kent, Sussex, Hants, Dorset, Devon, and Cornwall; and on the s. the French provinces of Artois, Picardy, Normandy, and Bretagne. On the e., it joins the North sea, at the strait of Dover, where it is narrowest, being only 21 m. wide from Dover to cape Grisnez. From this strait it runs w.s.w. for 280 m., and joins the Atlantic ocean at the Chops, with a breadth of 100 m. between the Scilly isles and Ushant isle. With an average breadth of 70 m., it is 90 m. wide from Brighton to Havre; 60 m. from Portland Point to cape La Hague; 140 m.—its greatest breadth—from Sidmouth to St. Malo; and 100 to 110 m. w. of the latter line. It occupies 23,900 sq. geographical m., and includes the Scilly isles, Channel isles, Ushant isle, isle of Wight, and many islets and rocks, especially off the coast of Bretagne. It is shallowest at the strait of Dover, where a chalk-ridge at the depth of 12 to 30 fathoms joins England and France. W. of this, it deepens to 60 fathoms, with some banks at 3 to 5 fathoms, and some hollows 5 to 30 fathoms deeper than the parts around. A coarse gravel covers the bottom. The English coast-line of the E. C. is 390 m. long, with an inshore depth of 12 to 55 fathoms, and the French coast-line of the E. C. is 570 m. long. Westerly winds prevail in the E. C., and the current, though imperceptible, is always from w. to east. The E. C. abounds in fish, of which the chief are pilchard, mackerel, and oysters.

ENGLISH CONSTITUTION. See PARLIAMENT.

ENGLISH DRAMA. See DRAMA.

ENGLISH LANGUAGE, which is now spoken by nearly 80 millions of the earth's inhabitants, is in its vocabulary one of the most heterogeneous that ever existed; a fact, the causes of which are to be traced in the history of England (q.v.). Its composition and grammatical character are thus described by M. Müller in his *Lectures on the Science of Language* (1861). "There is, perhaps, no language so full of words evidently derived from the most distant sources as English. Every country of the globe seems to have brought some of its verbal manufactures to the intellectual market of England. Latin, Greek, Hebrew, Celtic, Saxon, Danish, French, Spanish, Italian, German—nay, even Hindustani, Malay, and Chinese words—lie mixed together in the English dictionary. On the evidence of words alone, it would be impossible to classify English with any other of the established stocks and stems of human speech. Leaving out of consideration the smaller ingredients, we find, on comparing the Teutonic with the Latin, or Neo-Latin, or Norman elements in English, that the latter have a decided majority over the home-grown Saxon terms. . . . M. Thommerel, who counted every word in the dictionaries of Robertson and Webster, has established the fact, that the number of Teutonic or Saxon words in English amounts to only 13,230 against 29,853 words which can either mediate or immediately be traced to a Latin source. On the evidence of its dictionary, therefore, and treating English as a mixed language, it would have to be classified together with French, Italian, and Spanish as one of the Romance or Neo-Latin dialects. Languages, however, though mixed in their dictionary, can never be mixed in their grammar. . . . We may form whole sentences in English consisting entirely of Latin or Romance words; yet whatever there is left of grammar in English bears unmistakable traces of Teutonic workmanship. What may now be called grammar in English, is little more than the terminations of the genitive singular and nominative plural of nouns, the degrees of comparison, and a few of the persons and tenses of the verb. Yet the single *s*, used as the exponent of the third person singular of the indicative present, is irrefragable evidence that in a scientific classification of languages, English, though it did not retain a single word of Saxon origin, would have to be classed as Saxon, and as a branch of the great Teutonic stem of the Aryan family of speech." See PALEOGRAPHY; PHILOLOGY.

In tracing the growth of the E. L., the history is usually divided into *four* leading periods: the *Anglo-Saxon period* (440 A.D. to 1066 A.D.); the *Semi-Saxon period* (from 1066 A.D. to 1250 A.D.); the *Early English period*, comprising the two periods of *old* and *middle English* (from 1250 A.D. to 1550 A.D.); and the *Modern English period* (from 1550 A.D. to the present time). But this nomenclature and these divisions are now impugned by an increasing number of scholars, who affirm, not without reason, that English was always English, and never "Anglo-Saxon;" that the fact of its being inflected in the period before the Norman conquest, and losing most of its inflections in later times, is no reason at all for speaking of it as if it were two or even three different languages, and that we have no warrant in the usage of the inflected period for calling our forefathers or their speech anything but English. It is certainly very misleading to name the period immediately succeeding the conquest *Semi-Saxon*, because it induces people to imagine that the so-called "Saxon," that is, the English, element of our language had begun to be mixed up with foreign ingredients, though, in point of fact, its two great monuments, *The Chronicle*, and Layamon's *Brut*, are all but absolutely free from such. It is proba-

ble, therefore, that the old divisions and their designations will before long be abandoned, and they are only retained here out of respect to a usage which has penetrated modern English literature.

As early as the 5th c., Teutonic invaders from the continent settled in this country, and drove the original Celtic-speaking inhabitants to the n. and w. of the island; so that before the battle of Hastings (1066), the tongue of the conquerors had been spoken in England for at least 600 years. The final absorption, after numerous conflicts, by the kings of Wessex, or West Saxons, of the various states of the "Heptarchy," in the 9th c., went far to make the ruling speech of the land identical with that of Berkshire and Hants, the recognized center of the predominant sept. The use, besides, of this southern Anglo-Teuton speech as the chief instrument of literary communication, was permanently confirmed by the influence of king Alfred, a native of Berks. Further back than the time of this literary monarch, few existing remains of the language permit us to go; yet, from the writings of Cædmon, who was a North Anglian, and a few ecclesiastical MSS. of the kingdom of Northumbria, which extended from the Humber to the firth of Forth, it has been generally concluded that at least two dialects must have been used in the island—a northern and a southern one. The Anglian or northern dialect was, to some slight extent, marked by Scandinavian features; while the Saxon or southern dialect was more purely Low-Germanic, though the Anglian was also Low-German in all essentials. Some have accounted for the partial approximation of the Anglian dialect to Scandinavian by the fact that the Danes, at a later period, effected a settlement in the n.e. of England; but on the other hand, it is argued that "certain peculiarities of a Scandinavian character are to be found in the Anglian, even of a date anterior to the first Danish occupation of a part of England in the latter half of the 9th century." Nor would this be at all surprising if we admit that the Angles came from that corner of Slesvig still called "Angeln," or indeed from any region n. of the Elbe. Some philologists, again, insist on distributing the Anglo-Saxon language into more dialects than two; but it will be sufficient if the reader bear in mind the two which have been mentioned. It is important to notice here that neither the Anglian nor the Saxon borrowed almost anything from the language of the conquered Britons; in other words, English is very nearly free of any Celtic element. On the other hand, a considerable, but not large, number of Latin words found their way into the English vocabulary before the Norman conquest, through the introduction of Latin Christianity, and the translation of Latin authors into English.

The period in the history of our English tongue incorrectly described as *Semi-Saxon* because the inflections that marked the earlier stage then began to give way, dates from a generation after the conquest until near the middle of the 13th century. Like every transition era, it was a period of confusion, both to those using the language, and to those desirous of tracing its history. The monks of the time, accustomed to the use of mediæval Latin, had in a great measure forgotten the grammar of their native language; and when they attempted to write it, did so very badly. The *Chronicle*, which in its latest form comes down to 1154, and Layamon's *Brut*, written about 1190 or 1200, exhibit traces of the breaking up of the grammar. The inflections and genders of the substantives, the definite and indefinite declensions of adjectives, are for the most part disregarded; a marked partiality is showed for weak preterits and participles; there is a constant substitution of *en* for *on* in the plurals of verbs; and the final *e* is often discarded; besides a great uncertainty prevailing in the government of prepositions. As regards the vocabulary itself, although employed in literature a century and a half after the Norman conquest, it exhibits, as already noticed, but few traces of Norman-French (only 90 words in 57,000 verses); proving beyond question that the immediate effects of that great change were by no means so important on the English tongue as they were at one time believed to be.

When we come to the *third* period in the history of English, commonly called *early English*, we have escaped most of the perplexities which attach themselves to the previous stage of our language. The tendency of the language to substitute an *analytical* for a *synthetical* structure is now seen vigorously at work. The "Anglo-Saxon" was tolerably rich in inflections, which are now largely got rid of. The various modifications of an idea are expressed by some relational word or words attached to the leading idea. During the second or semi-inflected period, the verbs suffered much less inflectional change than the substantives and adjectives; this will be found to hold throughout the entire 250 years of the era of reconstruction. In the fine poem of *The Owl and the Nightingale*, the Anglo-Saxon vowels *a*, *e*, *u*, in final syllables, are all represented by *e*, and the final *n* of the infinitive is beginning to disappear. In the chronicle of Robert of Gloucester we encounter, besides, a great number of French words (Dr. Marsh found 4 per cent in 10 pages), which had gradually become familiar to the people, through the presence of their Norman masters, and through the efforts of the latter to speak English after it was found impossible to supplant it by Norman French. The presence of French is, besides, very noticeable in the poetry of Chaucer and Gower; but there is no ground for the statement that these writers corrupted the language by a large admixture of novel French words. Dr. Morris is quite correct when he says (introduction to Chaucer's *Prologue*, etc., Clarendon press series), that Chaucer, "with few exceptions, employed only such terms as were in use in the *spoken* language, and stamped them

with the impress of his genius, so that they became current coin of the literary realm.* And Mr. Skeat remarks (introduction to *Piers the Plowman*, same series), that "Langland does the very same thing, employing Norman-French words freely whenever he wishes to do so." As to Scotland, again, in the Anglian counties lying south of the Forth, and as far north of it as English had got a footing, the language also underwent such changes as we have noted in the more southern dialects. Barbour, a Scottish contemporary of Chaucer, wrote purer English than Chaucer did, only because he used less French. Regarding the north-eastern dialects of Scotland, indeed, some diversity of opinion exists. Some antiquaries are of opinion that the large infusion of Norse or Scandinavian elements in these dialects is to be accounted for by the fact of a Norwegian kingdom having been maintained there more or less from the 9th to the 11th c.; while others allege that the language of the n.e. of Scotland is in substance and grammar as decidedly Anglian as that of Norfolk or Yorkshire.

We may here notice the question which has often been asked: Which of the early dialects spoken in England is the origin of the form now used? We have seen that in the pre-Norman period *two* were employed for literary purposes, a northern or Anglian, and a southern or Saxon, the latter of which, through political causes, was perhaps considered the more classical of the two. In the period, however, succeeding the Norman conquest, and more especially after 1250, we find not *two*, but *three* dialects; a northern, a midland, and a southern. The cause of this was probably the breaking up of the supremacy of Wessex after the battle of Hastings. Circumstances now gave prominence to the midland counties, in which arose the great universities, the rich monasteries, and many other religious foundations. One of its subdivisions, the east midland, was the dialect in which Ælfric, Robert of Brunne, Wicliffe, Gower, and, above all, Chaucer wrote. It had then become the speech of the metropolis, and had probably forced its way south of the Thames into Kent and Surrey. This, therefore, may be considered the immediate parent of modern English, but inasmuch as the midland gathered into itself from its very position many of the peculiarities of the dialects spoken north and south of it, sir Frederick Madden's view (*Layamon's Brut*, 1851), that we must look for the real groundwork of modern English in a gradual coalescence of the various dialects, may still be considered substantially correct. See Emerson, *History of the English Language* (1894).

ENGLISH LITERATURE, like every other mental product, is qualified by the history of the nation to which it belongs. The great social eras of a country's history have always been found to correspond with the great intellectual eras of her growth. It will, however, be sufficient for our purpose to arrange the literary annals of England into three periods: 1. The period antecedent to the Norman conquest; 2. The period extending from the Norman conquest to the English reformation; and 3. The period extending from the English reformation to the present day.

1. *The Period antecedent to the Conquest.*—This period possesses a literature composed in three distinct languages—the *Celtic*, the *Latin*, and the *English*. Regarding the Celtic literature, see **CELTIC NATIONS**, **IRISH LITERATURE**, and **WELSH LITERATURE**. The introduction of Latin literature into this country was considerably later than the Roman invasion of it. The cultivation of the letters of Rome followed as a necessary consequence on the introduction of Christianity into the country. Towards the close of the 6th c., St. Augustine landed in the south of England, and laid the foundations of the Anglo-Catholic church. These great evangelists, however, rather prepared the way for literary effort on the part of others, than were themselves literary. The earliest names that we encounter are Gildas, Nennius, Bede, Alcuin, Asser, and Erigena. After the immigration of the Angles and Saxons into Britain, this people began to form a literature of their own. Their three historical poems—*The Gleeman's Song*, *The Battle of Finnesburgh*, and *The Tale of Beowulf* (q.v.)—are mainly versions of events which happened on the continent before the descent on the shores of England. Except the remarkable religious poems of the Northumbrian monk Cædmon, in the 7th c., little more of any moment in verse has been handed down to us by the English people who lived before the conquest. But this people, though comparatively poor in poetry, are eminently simple and straightforward prose writers. King Alfred discarded Latin in all his communications with his subjects, and in consequence the native language made an impressive start throughout the whole of England. From the *Chronicle*, which is made up from the MS. of several conventual records, modern scholars have derived special and valuable information. Portions of the sacred Scriptures were translated into English, several of the leading men of the time, such as Ælfric, Bede, and Alfred, lending their assistance. Sermons and grammars, glossaries and medical treatises, geographies and dialogues between Solomon and Saturn, make up the file of this period of the literature.

2. *The Period extending from the Norman Conquest to the English Reformation.*—The conquest had the effect of changing the language of the court, the schools, and the tribunals of justice; it took but little effect on the native inhabitants. In a few centuries, owing partly to the obstinacy with which the English people clung to their mother-tongue, and partly to the circumstance that long settlement in England and political antagonism to France had practically changed the descendants of the Norman conquerors into English nobles, and inspired them with English feelings, the latter began to

abandon the use of French. "In 1349, boys ceased to learn their Latin through the medium of this tongue; and in 1362 (the 36th year of Edward III.), it was directed by act of parliament that all pleadings in the law-courts should henceforth be conducted in English, because, as is stated in the preamble to the act, French was become much unknown in the realm" (Morris's *Historical Outlines of English Accidence*, 1872). In a generation or two after the conquest, classical and theological learning made very considerable progress. Monasteries were busy, and the English universities were both by this time founded; while an interchange of teachers and pupils constantly went on between the English seminaries and those of France and other countries. Lanfranc and Anselm, Hales and Duns Scotus, Michael Scot and Roger Bacon, had attained to a great eminence in speculative and in physical philosophy. Doubtless their thinking was more characterized by its hair-splitting ingenuity than by its solidity, but the 12th and 13th centuries stand out in a distinguished manner in England, and indeed throughout Europe, for their peculiar devotion to speculative studies. But all these philosophers wrote in Latin, as did the historical writers of the same period, of whom the chief were William of Malmesbury, Geoffrey of Monmouth, Giraldus Cambrensis, and Matthew Paris. A literary feature of the age which must not be overlooked was the frequency of satire expressed in rhymed Latin verse. The most notable of the mediæval satirists was Walter Mapes, to whom is ascribed (though the evidence of his authorship is not conclusive) certain clever half-scurrilous poems, from one of which, the *Confessio Goliæ*, have been extracted a number of verses, commonly but erroneously spoken of as a "drinking-song" (see MAPES). The satire passed from the clergy, and was directed against the feeble king (John). De Montfort and the other great barons who distinguished themselves at Runnymede, are the theme of popular praise. In the same Latin tongue was composed the oldest legendary work of the middle ages. The *Gesta Romanorum* (q. v.) is a compilation of uncertain origin. The stories themselves are in many cases of great antiquity, and in their earliest forms can be traced to the distant east. In their Latin dress they were the property, not of England only, but of all western Christendom, and their only claim to notice in a special survey of E. L. arises from the fact that their editor, Elinandus, was perhaps an Englishman, and that they have furnished (at second or third hand) incidents and plots to the genius of Shakespeare and Scott. In the same relation to E. L. stands *The Seven Wise Masters*, traceable back to India, but known to all western Europe in a Latin form, and to England in particular under the title of the *Process of the Seven Sages*. The French Fabliaux affected our literature but little before the time of Chaucer. On the other hand, the romances of chivalry, rude and spirited, pathetic and imaginative, are well worth the attention of the student of English literature. The best of these, first written in French, but afterwards translated into English, celebrate the glory and fall of king Arthur and his knights of the Round Table, of which splendid use has recently been made by Alfred Tennyson in his *Idyls of the King*.

Meanwhile the English tongue was undergoing those serious grammatical and phonetic changes to which reference has already been made. During this half-chaotic stage it was scarcely fit to be a vehicle of literary expression, even if the ignorance and helplessness of the conquered people had not of themselves been sufficient to prevent the growth of a vernacular literature. The first indication of reviving life is the appearance of Layamon's *Brut* (see LAYAMON) about the close of the 12th century. The next century is comparatively rich in writers who use the English tongue, and whose works, if not masterpieces of artistic skill, are at least invaluable for linguistic purposes. The most important of these writers are Orm, Guildford, and Robert of Gloucester.

The period of what is called *Early English*, embracing the 14th and 15th centuries, is one of great importance, both in the progress of English history and of English literature. The translation (the first ever executed) of the Bible into English, which was completed by Wicliffe about 1380, is a work of great value, not only as a monument in the religious history of our nation, but in a philological point of view, being, as it is, all but first among the prose-writings in that form of the English tongue which is now in use. The principal book which precedes it, and the very oldest written in "early English," is sir John Mandeville's account of his eastern travels (1356). Somewhat later (between 1390 and 1400), Geoffrey Chaucer, the genuine father of English poetry, published his *Canterbury Tales*. A shrewd and sagacious observer, he has left behind him in these *Tales* a series of sportive and pathetic narratives, told with such a wonderful power of tenderness and humor, in such a simple, healthy style (although his vocabulary is largely modified by French, and is by no means a "well of English undefiled"), that they have been the wonder and delight of all succeeding times. Laurence Minot, Richard Rolle, Langland, author of *Piers the Plowman*, and Gower, fitly close round Chaucer as contemporaries who wrote more or less vigorous verse. About the same period flourished in Scotland John Barbour, whose epic narrative, *The Brus*, written about 1376, is incomparably the greatest of all the metrical chronicles. In the following century (the 15th), and in the early part of the 16th, occur in England the names of John Lydgate (1430), whose *London Lyckpeny* is still agreeable reading; Alexander Barclay, whose *Ship of Fools* was printed in 1509; John Skelton, author of the scurrilous satires of *Colin Clout* and *Why Come ye not to Court?* (died 1529); Howard, earl of Surrey (beheaded 1546-47), who wrote the first sonnets and the first blank verse in the English tongue; and sir Thomas Wyatt (died 1541). The prose writers of this period are sir John

Fortescue, chief-justice of the King's Bench under Henry VI., who flourished 1430-70, and who wrote, among other things, a tract on the *Difference between an Absolute and Limited Monarchy*, as it more particularly regards the *English Constitution*; William Caxton, who introduced printing into Britain in 1477—the first book ever printed in this country being a translation of the French work *Le Recueil des Histoires de Troye*; sir Thomas Malory, whose *Morte d'Arthur* (1469-70) is the final form of the Arthurian romance; Hall, an English lawyer (died 1547), who wrote a chronicle of the *Wars of the Roses*; and Tyndale, burned (1536) for heresy. In Scotland, during the same period, we encounter in poetry the names of James I., king of Scotland (murdered 1437), author of the *King's Quhair*, etc.; Andrew Wyntoun, prior of Lochleven, whose *Orygynale Cronykil of Scotland* was completed about 1420; Blind Harry, author of *The Adventures of William Wallace*, a work written about 1460, and long exceedingly popular with the Scottish peasantry; Robert Henryson (died circa 1500), author of *The Testament of Cresseid*, etc.; William Dunbar (died about 1520), whose *Dance of the Seven Deadly Sins* shows him to have possessed great boldness and vigor in his delineations of character; and Gavin Douglas (died 1522), whose best work is a translation of Virgil's *Æneid* into English verse—at least into what both Scotchmen and Englishmen then reckoned English verse.

3. *The Period extending from the English Reformation to the Present Day.*—Among the brilliant works of the Elizabethan age, there is probably none of which we may not detect germs in some of the efforts which were made in the century that preceded. In theology, the names of Latimer (burned 1555), of Cranmer (burned 1556), and of Ridley (burned 1555), shine forth conspicuously; and it is sufficient to mention sir Thomas More (beheaded 1535), author of *Utopia*, a curious philosophical work, and Roger Ascham (died 1568), as excellent miscellaneous writers of that time. The last-mentioned, indeed, exercised no inconsiderable influence on the development of the English tongue, and his *Scholemaster* is a work that is even yet influential. We may here mention the Scotchmen, Mair or Major, sir David Lyndsay, Boece, Melville, and, above all, George Buchanan, who is universally admitted to have been one of the finest classical scholars that ever appeared in Christendom.

The origin of the English drama is discussed in the articles *DRAMA* and *MYSTERIES AND MIRACLE PLAYS*. It is therefore only necessary here to note that the first English comedy, *Ralph Roister Doister*, was written by Nicholas Udall about 1552-53, and the first English tragedy, *Gorboduc*, or *Ferrex and Porrex*, by Sackville and Norton a few years later. The era on which we are next to look, the Elizabethan, is the most brilliant in the literary history of England. We may quote here the words of lord Jeffrey: "In point of real force and originality of genius, neither the age of Pericles, nor the age of Augustus, nor the times of Leo X. or of Louis XIV., can come at all into comparison. For in that short period we shall find the names of almost all the great men that this nation has ever produced; the names of Shakespeare, and Bacon, and Spenser, and Sidney; of Raleigh, and Hooker, and Taylor; of Napier, and Milton, and Cudworth, and Hobbes; and many others—men, all of them not merely of great talents and accomplishments, but of vast compass and reach of understanding, and of minds truly creative; not men who perfected art by the delicacy of their taste, or digested knowledge by the justness of their reasonings; but men who made vast and substantial additions to the materials upon which taste and reason must hereafter be employed, and who enlarged to an incredible and unparalleled extent both the stores and the resources of the human faculties." Even the minor dramatists of the time, such as Marlowe and Chapman, Beaumont and Fletcher, Jonson and Drummond, are all nearly the equals of any succeeding poets that have appeared. In the latter half of this period a new class of poetic writers started up, who were lyrical rather than dramatic, and whose occasional verses, sometimes descriptive, sometimes amatory, and sometimes religious, are characterized by a bright and delicate fancy, as if morning sunbeams glittered on their pages. These are George Wither, William Browne, Francis Quarles, and George Herbert, "the sweet psalmist of the 17th c." (as Emerson calls him). The last forty years of the 17th c. are generally known as the age of the restoration and the revolution. During this period, the literature of the stage was disgraced by its indecency. Charles II. and his court had brought back with them from France a love of polite profligacy, which found its most fitting expression in the comedy of intrigue. Four names stand out conspicuous as "sinners above all men in that generation"—Wycherly, Congreve, Vanbrugh, and Farquhar. Yet theology could boast of such names as Baxter, Owen, Calamy, Collier, Leighton, South, Tillotson, and Barrow. This was also the epoch when the great Milton, driven into the shades of obscurity by political adversities, fulfilled the uttered hope of his youth, and wrote "something which posterity will not willingly let die." About this time, too, Walton angled, and Butler burlesqued dissent; Marvell turned his keen irony against the high church; Locke and Newton speculated and discovered; and John Dryden, the literary chief of the time, "found the English language," according to Dr. Johnson, "of brick, and left it of marble."

The literary history of the 18th c., and of the reign of Queen Anne, has been variously estimated. "If it was overvalued," says Prof. Spalding, "by those who lived in it, and in the age that succeeded, it has assuredly been undervalued in our own day. It was long glorified as the Augustan age of English literature; but among ourselves it has been set aside as a skeptical, utilitarian age, when poetry could find no higher field

than didactic discussion, and prose found nothing to amuse but comic and domestic narrative, or bitter and stinging satire. The truth, as usual, lies in the middle. This age was far from being superior to every era that had gone before it, and it was not quite so low as some of its hostile critics have represented. One thing, however, is beyond dispute, viz., that the *form*, both in poetry and in prose, had come to be much more regarded than the *matter*. Addison, Swift, and Johnson may be taken as types of the prose writers of this century. The first, for ease and grace, is unmatched in any age; the second stands equally high for rough and pointed vigor; and the third is famous for his ponderous, finely balanced sentences, the dignity of which not unfrequently surpassed the sense. Defoe created no school, but the author of *Robinson Crusoe* will live for ever. The poetry of the time is represented by Pope, and it has been gravely asked whether he was a poet at all. He certainly versified with brilliant elegance, and the terror which his polished epigrams excited in the breasts of his enemies, showed him to possess a force of genius which at least demands our admiration. Young and Akenside were perhaps animated by a higher poetic sense, but they accomplished much less; and the same may also be said of Thomson, Gray, Collins, Beattie, and Cowper. Incomparably the greatest poet, however, of the 18th c. was Robert Burns, though he wrote in a dialect of English that has since become a *patois*, and even then, though used by a nation, was not the recognized standard of literary expression. Richardson, Fielding, Smollett, Sterne, Goldsmith, and Mackenzie are its novelists; Hume, Robertson, and Gibbon, its historians; Butler, Berkeley, Clarke, Shaftesbury, Hume, Paley, and Adam Smith its philosophers.

The first quarter of the nineteenth century belongs to the Georgian era of English literature, an epoch second only to the great Elizabethan era in brilliancy, and even superior to that in respect to the variety and range of its productiveness. The period was one of great and general unrest. Vast social, moral, economic, and political problems demanded solution. In France the ferment of the times had resulted in the terrible upheaval of the Revolution, and the Napoleonic wars which followed were involving all the nations of Europe. In England, as elsewhere, the minds of men were stirred to their depths concerning the vital questions of the hour, and their utterances in literature were characterized by vigor, earnestness, and simplicity. Two great schools of poetry originated almost simultaneously: one, the contemplative and ideal; the other, the romantic and sentimental. The latter developed rapidly and was predominant during the era, the former was of slower growth, and has much influenced the verse of our own time. The great reviews and magazines which came into existence early in the century had an important effect upon its literary progress. The *Edinburgh Review* (Whig) was founded in 1802 by Sydney Smith, Brougham, and Jeffrey, and the latter soon became its editor. Its severe criticisms of contemporary authors caused an immense sensation, and evoked Byron's sharp retort entitled *English Bards and Scotch Reviewers*. The *Quarterly Review* was established in 1809 as the organ of the Tory party, and the truculent Gifford was its first editor. Among its contributors were Southey, Scott, and Lamb. Somewhat later came *Blackwood's Magazine*, for which Wilson, as "Christopher North," wrote the celebrated *Noctes Ambrosianæ*, and Lockhart, his trenchant criticisms. There was also the *London Magazine*, to which Lamb contributed his delightful *Essays of Elia*, De Quincey, his *Confessions of an Opium Eater*, and Carlyle, articles on Schiller, and which numbered also among its writers Hazlitt, Leigh Hunt, and Cary. All these great periodicals exerted a powerful influence upon literature, especially in the development of the art of criticism, which has attained such importance now as to be almost an independent profession in the domain of letters. In this limited sketch it will only be possible briefly to characterize a few of the more illustrious authors of the period. Wordsworth, Coleridge, and Southey were all for a time residents of the Lake Country, and were more or less intimately associated; Coleridge and Southey had married sisters, and Wordsworth and Coleridge had published a volume of *Lyrical Ballads* to which each had contributed, but the nickname of "The Lake Poets," applied to them by an Edinburgh reviewer, was incorrect as implying that the three belonged to the same school of poetry. Wordsworth and Southey were quite different in their aims and methods, and as for Coleridge, the "inspired creator of splendid fragments," he was incapable of long pursuing any definite aim. Wordsworth, earnest, spiritual, philosophic, possessed of clear insight and lofty imagination, was the founder of the contemplative school of poetry. He was an intense egotist and delighted to record his own emotions as aroused by the phenomena of nature, or by intercourse with his fellow-men. To his receptive mind all objects and events were richly suggestive. His imagination was accustomed to exercise itself upon the simplest themes, and from them he derived material for profoundest thought. His poetry is, however, very unequal, and his longer productions contain much that is prosaic and uninteresting. Deficient in the sense of humor, he failed in some of his early poems to distinguish between the simple and unaffected and the trivial and commonplace, but his influence was most wholesome and valuable in directing men to a closer study of nature, and in showing them that the realm of poetry is far wider than they had supposed. Among his best works are the *Ode to Duty*, *Ode on Intimations of Immortality*, *Laodamia*, parts of the *Excursion*, and many of the sonnets and short lyrical poems. A discussion of Wordsworth's theories in regard to poetical composition would require too much space, but the reader will find them ably treated by several of the authorities referred to at the close of this article. The versatile and exuberant genius of Coleridge, as shown in his

wonderful gift of discourse, profoundly impressed his contemporaries. He has left but little poetry, but that is of the highest order, and of ideal beauty in form and spirit. The *Ancient Mariner*, *Christabel*, *Genevieve*, *Kubla Khan*, and *Youth and Age* are most sweet and melodious. The supernatural element in the *Ancient Mariner* and *Christabel* gives them a strange fascination, and the meter of the latter is charmingly diversified by counting only the four accented beats of each line, while the number of syllables varies from seven to twelve. As a critic he is remarkable for sympathy and insight. His *Aids to Reflection* are rich in suggestiveness, and the influence of his fertile thought has been deeply felt by the best minds of the century. Southey, poet laureate, was a fluent and copious writer of verse, which, notwithstanding its gorgeous coloring, does not rank very high as poetry. His description of his return to his home after a journey on the continent, contained in the Proem to his *Pilgrimage to Waterloo*, and some of his short poems, as *After Blenheim*, are charming. Among his prose works are the quaint and curious *Doctor* and an admirable *Life of Nelson*. Scott is the great exemplar of the romantic school. His first original work of importance, *The Lay of the Last Minstrel*, is a romance of Border Life in the 16th century. It met with instantaneous success, and *Marmion* and *The Lady of the Lake* were received with ever-increasing delight. His later poems were less popular, for a new luminary, Byron, had appeared, of sufficient brilliancy to eclipse even Scott. The latter then turned his attention to prose, and with the long series of *Waverley Novels*, in which his vivid narrative and descriptive powers had full scope, the genial "Wizard of the North" won a still more enduring fame than that which he had gained as a poet. Byron, like Scott, is clear, fluent, and vigorous, but far more fervid and impassioned. He had no dramatic gift. His chief power lay in description. The public have always been disposed to identify the poet himself with his morbid and cynical heroes. But Moore gives a much more attractive picture of the character of his friend, and Byron has avowed that his typical hero, the melancholy and misanthropic *Childe Harold*, was modelled after Dr. Moore's *Zeluco*. Byron's undoubted genius is not fully evident in the first two cantos of *Childe Harold's Pilgrimage*, and the sudden fame which followed their publication has puzzled the critics. Prof. Minto plausibly suggests that the instantaneous and rapturous applause that greeted these cantos was largely due to the opportune moment at which they appeared, when the public mind was regarding with the most intense interest the localities described: Spain, which was then the seat of the war with Napoleon, and Greece, the description of whose fallen glories touched the hearts that were at that time trembling for the future of England. Among Byron's best works are the third and fourth cantos of *Childe Harold's Pilgrimage* and the fine sonnet *On the Castle of Chillon*. Moore, sparkling and humorous, was one of the most popular and successful authors of his day, but his posthumous is not equal to his contemporary fame. He wrote many graceful and tender songs for Irish national melodies. *Lalla Rookh*, his longest work, consists of a brief prose romance which forms the framework of four Oriental poems. His *Life of Byron* is a trustworthy and creditable biography. Campbell's reputation rests mainly on his spirited lyrical poems, *Hohenlinden*, *The Battle of the Baltic*, *Lord Ullin's Daughter*, and others. Crabbe had in the previous century produced some realistic pictures of peasant life, and after an interval of twenty-two years resumed his pen with greater skill in *The Parish Register*. Of Shelley, Dowden says, "No other poet has pursued with such breathless speed on such aerial heights the spirit of ideal beauty." Swinburne, who is an ardent admirer of Landor, places him midway between Shelley and Byron, as far below Shelley as he is above Byron. *Prometheus Unbound* is the masterpiece of Shelley's longer works; *The Cenci* is a powerful tragedy. The *Ode to the West Wind*, *To a Skylark*, and *The Cloud* are exquisite lyrics. The early death of Keats cut short a career of unusual promise. His genius is akin to that of Shelley, and his beautiful poems, the *Ode to a Nightingale*, the *Ode to Autumn*, and that *On a Grecian Urn*, had he written nothing else, would have assured the immortality which he hopefully but modestly anticipated in writing to his brother, "I think I shall be among the English poets after my death." Leigh Hunt (the chief of the "Cockney" school of poets, as they were satirically dubbed by the *Edin. Rev.*), although not free from certain foibles and affectations, wrote both verse and prose of high merit. Among his chief works are the narrative poem, *The Story of Rimini*, and an excellent play called *A Legend of Florence*. His best-known poem is the little apologue *Abou Ben Adhem*. His critical works, *Imagination and Fancy*, and *Wit and Humor* evince his admirable taste and his alertness in discerning minute felicities. Among the lesser poets of this era are H. K. White, Jas. Montgomery, R. Bloomfield, the Scotch poets, J. Grahame, A. Cunningham and W. Tennant, J. Wolcot ("Peter Pindar"), the satirist, Mrs. Barbauld, whose exquisite little apostrophe to *Life* is sufficient to keep her memory green, C. Wolfe, whose fame is also dependent on a single fine poem, *The Burial of Sir John Moore*, Joseph Blanco White, author of *The Sonnet to Night*, one of the most beautiful in the English language, Mrs. Hemans, Mrs. Opie, John Clare, S. Rogers, the genial banker-poet, the brothers J. and H. Smith, who wrote the witty *Rejected Addresses*, Mrs. Tighe, F. Mahony ("Father Prout"), Praed, and Bp. Heber, whose hymns are familiar to all. Charles Lamb, the delightful essayist, has a quaint and somewhat antique style derived from his fondness for certain writers of a bygone age. His playful fancy, his delicate humor, and his sweet and lovable disposition endear him to all. His reputation chiefly rests on the *Essays of Elia*, but he has written a few graceful poems, as *Hester*, *Savory* and *The Old Familiar Faces*.

Before the appearance of Scott's *Waverley*, Maria Edgeworth, in *Castle Rackrent* and other tales, pictured Irish life and character with attractive and minute fidelity. A little later Jane Austen, in *Pride and Prejudice*, *Emma*, and *Persuasion*, and Susan Ferrier, in *Marriage and The Inheritance*, pictured with similar fidelity provincial life in England, and life in the Scotch Highlands, and with a charm which has not yet lost its potency. Other celebrated romances of the time are: Mrs. Radcliffe's *Mysteries of Udolpho*, Godwin's *Caleb Williams*, Matthew Gregory Lewis's *Monk*, Mary Shelley's *Frankenstein*, Jane Porter's *Scottish Chiefs* and *Thaddeus of Warsaw*, Lady Morgan's *Wild Irish Girl*, Beckford's *Vathek*, Croly's *Salathiel*, and Peacock's *Headlong Hall* and other curious tales. John Galt's Scotch and Gerald Griffin's Irish stories are of this period also. Among the dramatists are G. Colman, Jr., and Joanna Baillie, whose much-admired *Plays on the Passions* are now forgotten. Holcroft's *Road to Ruin*, Knowles's *Virginus*, *The Hunchback*, and *The Wife*, and Tobin's *Honeymoon* are still occasionally seen upon the stage.

The Scottish school of philosophy founded by Reid was represented by Dugald Stewart, Dr. Thos. Brown, and Sir James Mackintosh, the latter of whom ably opposed the utilitarian theory of Bentham and of his distinguished follower, James Mill.

In accuracy, in vividness of portrayal, and in the philosophic interpretation of the relationship of events, the historians of the 19th century have made so marked an advance as to supersede all of the older historians except Gibbon. The historians of the Georgian era are the calm and judicious Hallam, author of a *View of the State of Europe during the Middle Ages*, a *Constitutional Hist. of Eng.*, and an *Introd. to the Literature of Europe in the 15th, 16th, and 17th Centuries*; John Lingard, author of a well-written and honest *Hist. of Eng.* as seen from a Roman Catholic point of view; James Mill, who wrote a severe but impartial *Hist. of India*; Sir James Mackintosh, whose *Vindiciae Gallicæ* was the ablest argument against Burke's denouncement of the French Revolution (though he was afterwards led by the excesses of that bloody period to modify his opinions), and whose unfinished *Hist. of the Eng. Rev. of 1688* is a brilliant and valuable fragment; Sharon Turner, author of a *Hist. of the Anglo-Saxons*, and *Hist. of Eng. in the Middle Ages*; and Henry Hart Milman, whose principal work is his able *Hist. of Latin Christianity*. Sir H. Davy and Whewell are the most prominent writers on science, and Hall, Chalmers, and Irving on theological topics.

The poetry of the Victorian era is mainly lyrical. Its principal characteristics are intellectuality, refinement, and exquisite finish. The best representative of this school is Tennyson. "In technical excellence, as an artist in verse," says Stedman, "Tennyson is the greatest of modern poets." In *Memoriam*, the noble elegy in memory of A. H. Hallam, and the *Idylls of the King*, especially *Morte d'Arthur* and *Guinevere*, are his masterpieces. Landor ranks high as a poet, and is even more distinguished as a prose writer. *Count Julian* is a noble tragedy, and the *Hellenics*, translations made in his old age of his own Latin poems written many years before, are among the most beautiful of the shorter poems. His *Imaginary Conversations*, particularly the *Citation of Shakespeare*, the *Pentameron*, and *Pericles and Aspasia*, are marvelous productions of genius and learning. Hood's prominent characteristics are humor and pathos. He is an inveterate punster. Among his most notable poems are *The Bridge of Sighs*, *The Song of the Shirt*, *The Dream of Eugene Aram*, and the satire, *Miss Kilmansegg*. Procter ("Barry Cornwall") is chiefly distinguished for a great variety of charming songs and lyrics. Browning, like Tennyson, is profoundly intellectual, but far more impassioned. With him art and finish are decidedly subordinate. His thoughts crowd one upon another, and his sentences frequently become so involved and intricate as to be obscure. His insight into the workings of the human mind is wonderful. *The Ring and the Book* is perhaps his greatest work. The prelude briefly narrates the story on which the poem is founded (the trial of an Italian for wife-murder), and tells that it was found in an old book picked up by chance at a book-stall. This story, as given by the chief witnesses at the trial, as commented on by "half Rome" and by "the other half Rome," as discussed by the opposing lawyers, as told by the defendant, and as summed up by the Pope, is repeated in detail in each of the ten principal divisions of the poem, and yet the interest of the reader is held to the end. It is a wonderful achievement. But Browning's inequality of performance is shown in this masterpiece, in which occur certain passages of mere affectation and clap-trap, such as no poet of lesser reputation would dare to publish. The spirited poems *How they Brought the Good News from Ghent to Aix*, *The Lost Leader*, *Hervé Riel*, and the *Pied Piper of Hamelin* are general favorites. In the *Dramatic Romances and Lyrics*, *Men and Women*, and *Dramatic Idylls* are gathered the best of his shorter poems. Mrs. Browning ranks as the foremost among women poets. Intellectual, impassioned, sometimes obscure and wanting in finish, she has merits and faults similar to those of her distinguished husband. All her writings breathe a firm and abiding trust in God, and a tender and sympathizing love for humanity. Among her chief works are *Aurora Leigh*, a narrative poem in nine books, into which, she says, her "highest convictions upon life and art have entered," but which is not, on the whole, her most successful production; *A Drama of Exile*, the subject of which is the expulsion of Adam and Eve from Eden; the noble *Vision of Poets*; and the lovely, so-called, *Sonnets from the Portuguese*, which are, in fact, a record of her own heart-experience. She felt an ardent interest in the enfranchisement of Italy, and some of her strongest and most impassioned poems, as *Casa Guidi Windows* and *Mother and Poet*, have reference to the struggle of that country for nationality. Mrs. Browning

had a thorough acquaintance with the Greek language and literature, and translated the *Prometheus Bound* of Æschylus and various other Greek, and some Latin and German poems. Matthew Arnold is a poet of much refinement, and is still more eminent as an essayist and critic. *Sohrab and Rustum*, *Balder Dead*, *The Scholar-Gipsy*, and the beautiful elegy, *Thyrsis*, are some of his best productions. Robert Buchanan as poet is a true interpreter of Nature. He is also a sympathetic and candid critic. Among his finest poems may be mentioned *The Scairth o' Bartle*, *The Ballad of Judas Iscariot*, and *Lights of Leith*. He has written some excellent dramas also. D. G. Rossetti, quaint in diction and ornate in style, has composed many exquisite sonnets and dramatic lyrics, and has made admirable translations from the early Italian poets. *The Blessed Damozel* is one of his best-known poems. Wm. Morris, a most facile and melodious poet, is a follower of Chaucer. His *Earthly Paradise* is modeled after the *Canterbury Tales*. In the prelude to each section he faithfully paints Nature in her various moods throughout the year, and the twenty-four tales of the voyagers are most skilfully narrated. In *Life and Death of Jason*, *Sigurd*, and *House of the Wolfings* he maintains nearly the same high level as in the *Earthly Paradise*, showing a wonderful ease and grace whether in verse or prose. A. C. Swinburne, a most accomplished linguist and scholar, has employed various new metres, and has developed hitherto unknown capabilities of the English language in rhythm and melody. *Atalanta in Calydon* represents perfectly the form and spirit of the old Greek drama. *Chastelard*, *Bothwell*, and *Mary Stuart*, written at different periods of the poet's career, compose a grand dramatic trilogy. Of several fine elegies, the most beautiful is *Ave atque Vale*, in memory of Baudelaire. As a critic Swinburne exhibits at times a rare insight, but his opinions are occasionally biased by a friendly partiality. Austin Dobson and Andrew Lang are charming writers of society verse, and their dainty reproductions of French metres have found many imitators. Other poets of the period are Palgrave, Clough, Monckton Milnes, Aytoun, Th. Martin, Macaulay, Bailey, A. Smith, Massey, Dobell, Patmore, Adelaide Procter, Jean Ingelow, Christina Rossetti, A. M. F. Robinson, Mrs. C. F. Alexander, "Owen Meredith" (Lord Lytton), C. Kingsley, Thackeray, Edwin Arnold, Lewis Morris, Jas. Thomson, E. Gosse, Locker, and Calverley. Miss Mitford will be better remembered for her fresh and pleasing sketches of *Our Village* than for her more ambitious dramas. Milman, Talfourd, Bulwer, C. Kingsley, R. H. Horne, Sir H. Taylor, Tennyson, Westland Marston, H. C. Merivale, W. G. Wills, and W. S. Gilbert have also written dramas, some of which, however, although of much literary merit, are better adapted for reading than for stage representation, Faber, Newman, Trench, Alford, Bonar, Chr. Wordsworth, Mrs. S. F. Adams, and Charlotte Elliott have increased the treasures of hymnology by original contributions, and Neale, Caswall, Miss Winkworth, and others, by excellent translations. Pattison, Symonds, E. Gosse, T. Watts, Caine, Dowden, Shairp, Sharp, Craik, Saintsbury, and Minto are cultivated and discerning critics, and several of them are graceful poets also.

The principal novelists and romancers of the period are Dickens, Thackeray, and "George Eliot" (Mrs. Cross). The genial humor of Dickens rendered him extremely popular. His characters are chiefly taken from the lower ranks of life, but are nevertheless unreal, as he is apt to make some one trait unduly prominent. *David Copperfield* and *A Tale of Two Cities* are among his best works. Thackeray is a satirist who never allows us to forget the foibles and vices of human nature, although he gives some beautiful illustrations of noble character. The personages that he depicts are mainly from the upper classes of society. *Henry Esmond*, *Vanity Fair*, and *The Newcomes* are his masterpieces. "George Eliot," with her original and powerful intellect, her learning, her remarkable skill in psychological analysis, and her keen sense of humor, undoubtedly stands first among the many women who have been successful in fiction. *Adam Bede* and *Romola* are the most famous of her works. The brilliant genius of the Brontë sisters won for them a hearty tribute of applause, and Charlotte Brontë, with *Jane Eyre*, *Shirley*, and *Villette*, fascinated a host of readers. Mrs. Gaskell, the biographer of Charlotte, was a delightful novelist herself, as *Mary Barton*, *Cranford*, and *Wives and Daughters* evince. Mrs. Craik's *John Halifax* is a charming story, and doubtless the favorite among her many books. Miss Yonge, Miss Amelia B. Edwards, Miss Ingelow, Mrs. Oliphant, Mrs. Anne Thackeray Ritchie, and "Lucas Malet" (Mrs. Harrison, daughter of Chas. Kingsley) have also won distinction as novelists, and several of them in other departments also. Disraeli wrote political novels; Bulwer, novels of society chiefly. Trollope has cleverly sketched various phases of clerical life. Charles Kingsley's versatile genius is displayed in *Hypatia*, *Westward Ho*, and the *Water-Babies*. Charles Reade is a vigorous writer with very decided mannerisms. His earlier novels, especially *The Cloister and the Hearth*, are his best. R. L. Stevenson has written romances, sketches of travel, and poems, in all of which the charm of style is exquisite. Other prominent novelists and romancers are Hardy, Blackmore, Black, Besant, McCarthy, Meredith, MacDonald, Mrs. Humphry Ward, Caine, Barrie, Kipling, Doyle, Du Maurier, Crockett, John Maclaren Watson, and Anthony Hope Hawkins.

The brilliant and dogmatic Macaulay has been of great service in popularizing the study of history. Formerly somewhat overestimated, he is now in danger of being undervalued. Carlyle is of all historians the most vivid and graphic. His style is unique, rapid, and full of allusions. As an essayist he is most inspiring and stimulating. Froude's literary skill is admirable in history, biography, and essays, but his great *Hist. of Eng. from the Fall of Wolsey to the Death of Elizabeth* is marred by undue par-

tiality for Henry VIII. His record of the reign of Elizabeth is valuable. Kinglake's *Hist. of the Crimean War*, though too long, is of great interest, but it also is affected by the prejudices of the author. Freeman's *Norman Conquest* is an able and trustworthy account of this early period of English history. J. R. Green's *Hist. of the Eng. People* is compendious, well proportioned, and reliable. Bryce's *American Commonwealth* is admirable for lucidity, accuracy, and candor. Stanley's *Hist. of the Jewish Church, Sinai and Palestine*, and *Hist. of Westminster Abbey* are delightful and valuable works. Buckle and Lecky have written notable books on the philosophy of history. Other important historical works are Arnold's *Hist. of Rome*; Merivale's *Hist. of the Romans under the Empire*, which forms a link between the histories of Arnold and Gibbon; Grote's *Hist. of Greece*; Bp. Thirlwall's *Hist. of Greece*; Rawlinson's *Hist. of Egypt*, and his various other histories of Oriental monarchies; Sir F. Palgrave's *Hist. of Normandy and England*; the *Hist. of the Peninsular War*, and *Hist. of the Conquest of Scinde*, by Sir W. F. P. Napier, the most distinguished military historian of England; Sir T. E. May's *Const. Hist. of Eng. since the Accession of Geo. III.*, which serves as a continuation of Hallam's *Const. Hist.*; Bp. Stubbs's *Const. Hist. of Eng.*; Justin McCarthy's *Hist. of Our Own Times* and *Hist. of the Four Georges*; and Goldwin Smith's *England and America, Civil War in America*, and *Irish History and Irish Character*. Ruskin, eloquent and dogmatic, and Hamerton, genial and stimulating, are prominent writers on art. Sir Wm. Hamilton is the leader of the Scotch school of metaphysics, and J. S. Mill, Lewes, and Spencer are representatives of the English materialistic school. Bain is an able exponent of the utilitarian view of ethics. J. S. Mill, Fawcett, Jevons, Thorold Rogers, and Harriet Martineau have written on political economy. Brewster, Faraday, Mary Somerville, Sir J. Herschel, R. Owen, Hugh Miller, Darwin, Tyndall, Huxley, Mivart, R. A. Proctor, W. K. Clifford, P. G. Tait, and Lubbock are distinguished in science, and several of them have written with marked force and beauty of style. Prominent philologists and writers on the English language are Max Müller, Isaac Taylor, Trench, Alford, Moon, F. Hall, T. L. K. Oliphant, and W. W. Skeat. Whateley, Lightfoot, Pusey, Conybeare, Howson, Ellicott, Alford, Trench, Robertson, Farrar, Liddon, Mozley, Stopford Brooke, Kingsley, Maurice, Martineau, Hanna, Tulloch, J. Caird, Spurgeon, Newman Hall, Drummond, F. B. Meyer, Faber, Newman, Manning, and Wiseman are eminent religious writers of various denominations. Want of space forbids the mention of other authors of note who have contributed to the departments of literature above mentioned, and it is also impossible to speak of many writers whose works cannot be included in those departments.

The following books are recommended for consultation: Wright, *Bibliographia Britannica Literaria*, 1. Anglo-Saxon Per.; 2. Anglo-Norman Per. T. Warton, *Hist. Eng. Poetry*. *Eng. Lit. Hist.*, 3 vols.: I., S. A. Brooke, *Eng. Poetry to Accession of King Alfred*; II., G. Saintsbury, *Elizabethan Era*; III., E. Gosse, *18th Century*. Chambers's *Cyc. of Eng. Lit.* Taine, *Hist. Eng. Lit.*, tr. by Van Laun. Bernhard ten Brink, *Hist. Eng. Lit.*, 2 vols.: I., *Early Lit. to Wiclif*, tr. by H. M. Kennedy; II., pt. 1, *Wiclif, Chaucer, Earliest Drama, Renaissance*, tr. by W. C. Robinson; Katharine Lee Bates, *The English Religious Drama*; Mrs. Oliphant, *Lit. Hist. of Eng., xviii.-xix. Centuries*; W. Minto, *Lit. of the Georgian Era*; E. C. Stedman, *Victorian Poets*; Bascom, *Philos. of Eng. Lit.*; G. L. Craik, *Compendious Hist. of Eng. Lit.*; A. W. Ward, *Hist. Eng. Dram. Lit.*; J. P. Collier, *Hist. Eng. Dram. Poetry*; T. H. Ward, *The English Poets*; H. Morley, *Lit. in the Reign of Victoria*; B. Tuckerman, *Hist. Eng. Prose Fiction*; J. Morley (ed.), *Eng. Men of Letters*; M. Arnold, *Essays in Criticism*; Dowden, *Studies in Lit.*; Swinburne, *Essays and Studies*; Frederick Ryland, *Chron. Outlines of Eng. Lit.*

ENGLISH PALE, or **IRISH PALE**, or **THE PALE**, a portion of Ireland brought under English rule before the complete subjugation of the whole island, corresponding nearly with the present province of Leinster, with the counties of Cork, Kerry, Waterford, Limerick, and Tipperary; but the boundaries varied at different times.

ENGRAFTING. See **GRAFTING**.

ENGRAILED, in heraldry, a line composed of a series of little half-moons, or semi-circles, supposed to have been made in it by hail. **E.** is the opposite of **invected**.

ENGRAVING, in its widest sense, is the art of incising designs, writing, etc., on any hard substance, such as stone, metal, or wood. Many branches of the art are of great antiquity; such as gem-engraving, cameo-cutting, and die-sinking. The more important of these ornamental and useful kinds of **E.** are described under their proper heads. But in a narrower sense, **E.** is the special designation of the art of cutting or indenting the surface of metal plates or of blocks of wood with designs, for the purpose of taking off impressions or *prints* of the designs on paper. This department of the art arose as late as the 15th c., the earliest wood-engraving with a date being 1423, and the earliest dated **E.** from a metal plate being 1461.

Wood-engraving differs from **E.** on metal in this, that on a metal plate the traces or marks which are to appear on the paper are cut or sunk into the plate, and when printed from are filled with ink, while the rest of the surface is kept clean; whereas in wood-engraving they are left prominent or in relief, and the blank parts of the design are cut away. Hence a wood-cut acts as a *type*, and is inked and printed from in the usual way. See **PRINTING**. This makes wood-engraving peculiarly suitable for the illustration of

books; as the blocks can be printed from along with the letterpress; while the impressions from a metal plate must be taken by themselves, and by a slow process. The further treatment of the important art of wood-engraving is reserved for a separate article; our attention at present being confined to E. on metal.

It is beyond our scope to enter into the practical details of the various processes; we can only aim at enabling a reader altogether ignorant of them to conceive how the effects may be produced, and to understand the terms currently used in speaking of this kind of art.

The metals most commonly used for E. are copper and steel, the former having the advantage of being more easily worked, the latter of greater durability. The processes of working are essentially the same in both. The several manners or styles of E. are distinguished as line-engraving, mezzotinto, stippling, and aquatinta.

1. *Line-engraving*—in which, as the name implies, the effect is produced by a combination of lines—is executed either by direct incision with the graver or the dry-point, or by a combination of incision with *etching*—a chemical process to be immediately described. The *graver* or *burin* is usually in the form of a quadrangular prism, fitted into a short handle. In making the incision, the graver is pushed forward in the direction of the line required, being held by the handle, at an angle very slightly inclined to the plane of the copper. A *scraper* is required to scrape off the barb or burr which is formed by the action of the graver and dry-point. The *rubber* is a roll of cloth dipped in oil, and is used to make the surface smooth. A *burnisher* is required to polish the plate, and erases any scratches which it may accidentally receive, and also to make lighter any part of the work which may have been made too dark. The *dry-point* is like a sewing-needle fixed into a handle, and is used to cut or scratch the finer lines. The graver cuts the copper clean out, the dry-point throws it up on each side; and in some cases this is not scraped off, but made use of till it is worn off, as it gives richness to the line.

In etching, the first step is to cover the plate with a composition of wax, asphaltum, gum-mastic, resin, etc., dissolved by heat; an outline of the design, made on paper in pencil or red chalk, is then “transferred” to the surface of this composition, by being passed through a press. The subject is then drawn on the ground with the etching-point, which cuts through it, and exposes the copper. *Etching-points* or *needles* resemble large sewing-needles shortened, and fixed into handles 4 or 5 in. long; some are made oval, to produce broader lines. A rim of wax being put round the plate, acid is poured on, and corrodes the copper not protected by the ground. If the acid is found not to have acted sufficiently, it may be applied again to the whole design, or only to portions of it, by *stopping up*, with a mixture of lampblack and Venice turpentine applied with a camel-hair pencil, what been sufficiently *bitten in*.

When a series of parallel lines are wanted, as in backgrounds, etc., an ingenious machine called a ruler is employed, the accuracy of whose operation is exceedingly perfect. This is made to act on etching-ground by a point or diamond connected with the apparatus, and the tracings are bit in with aquafortis in the ordinary way.

2. The process of *mezzotinto* is by no means so difficult as line-engraving. The plate is prepared by being indented or hacked all over by an instrument with a serrated edge, called a cradle, which is rocked to and fro upon it in all directions. The barb or nap thus produced retains the printer's ink, and if printed, a uniform dark surface would be the result. On this plate, after a tracing has been transferred, the engraver goes to work with tools called scrapers and burnishers—those parts of the ground most smoothed being the highest lights, and the ground the least operated on producing the deepest shadows. As the work proceeds, it may be blackened with ink, applied with a printer's ball or otherwise, in order to ascertain the effect. The design is sometimes etched on the plate by the ordinary process, before the mezzotinto ground is laid.

3. *Aquatint Engraving*.—By this method, the effect of drawings in Indian ink is produced; and at one time it was greatly made use of in rendering the drawings of Paul Sandby and our early water-color painters, and particularly prints for drawing-books. In this process, which is a very complex kind of etching, the ground, which is composed of pulverized rosin and spirits of wine, assumes when dry a granulated form; and the aquafortis acting on the metal between the particles, reduces the surface to a state that an impression from it resembles a tint or wash of color on paper. David Allan engraved his celebrated illustrations of the *Gentle Shepherd* in this manner. It has now gone almost entirely out of use, having, like E. in imitations of drawings in chalk or pencil, been in a great degree superseded by lithography.

4. In E. in *stipple*, which was much in vogue in the end of the last century, the drawing and effect are produced by small dots, in place of lines. Ryland, Bartolozzi, and Sherwin, excelled in this style. It is well suited for portraits; several of Raeburn's have been capitally engraved in stipple by Walker. It involves much more labor than mezzotint, and is now little practiced.

Plate-printing.—Copper-plates, engraved in any of the above styles, are ready for press as soon as they are finished by the engraver. The method of printing from them is very simple. Their engraved surface is daubed over with a thick oleaginous ink, so that the lines are effectually filled. As this dirties the whole face of the plate, it is necessary to clean it, which is done by the workman wiping it first with a piece of cloth,

and then with the palms of his hands, rubbed on fine whiting. It may be calculated that a hundred times more ink is thus removed than actually remains in the indentations; however, such is necessary. The plate being thoroughly cleaned, it is laid on a press, with a piece of damped paper over it; and being wound beneath a roller covered with blanket stuff, it is forced to yield an impression on the paper. The plate requires to be kept at a moderate warmth during the operation. The frequent rubbing of the plate with the hand to clean it, as may be supposed, tends greatly to wear it down; and such is the wear chiefly from this cause, that few copper-plates will yield more than a few thousands of impressions in good order. The earliest, called *proofs*, are always the best and most highly prized.

In consequence of this defect in copper, the practice of *engraving steel-plates*, for all subjects requiring a great many impressions, has now become very common. This process was introduced by the late Mr. Perkins of London, who originally softened the plates, engraved them, and then rehardened them—a practice now abandoned, as ordinary steel-plates can be worked upon by the burin, dry-point, scraper, and burnisher with perfect facility. Etching on steel-plates is executed much in the same way as in the process on copper. An E. on a steel-plate may be transferred in relief to a softened steel cylinder by pressure; and this cylinder, after being hardened, may again transfer the design by rolling it upon a fresh steel-plate; and thus the design may be multiplied at pleasure.

History of Engraving.—This most important invention, by which the productions of art are diffused without limit, is said to have been accidental, and is claimed for Tommaso Finiguerra, who first took impressions on paper about the year 1440. His employment was executing ornamental E., chiefly on articles used in religious services, such as small portable shrines, or altar-pieces. These were generally made of silver, and the designs engraved on them were filled up with a black composition, that hardened in a short time. This composition was called in Italian *niello* (from Lat. *nigellus*, dim. of *niger*, black), and the workers in it *niellatori*. It was the practice of Finiguerra, in the course of executing his work, to prove it by rubbing lampblack and oil into, and pressing paper over it; he thus obtained an impression of his work up to a particular stage, and was enabled safely to carry it on till it was completed. Finiguerra's title to the invention has been disputed; and in a recent work by J. D. Passavant, *Le Peintre-Graveur* (Leip. 1860), a strong case seems to be made out for its German origin. Be that as it may, the principal early Italian engravers who followed Finiguerra, were Bacio Baldini (born about 1436, died 1515); Sandro Botticelli (born 1437, died 1515)—he embellished an edition of Dante's *Inferno*, brought out in 1481; Antonio Pollajuoli (born 1426, died 1498, at Florence); Andrea Mantegna (born at Padua 1431, died at Mantua 1505); and Marc Antonio Raymondi (born at Bologna 1487 or 1488, died 1539), who executed his chief works at Rome. The most celebrated early German engravers were Martin Schoengauer (born at Colmar about 1455, died 1499); Israel van Meckeln, or Meckenen (born at Meckenen on the Meuse about 1450, and died 1523); Michel Wohlgemuth, who died in 1519; Albert Dürer (born at Nürnberg in 1471, died in 1528); and Lucas van Leyden (born at Leyden 1494, died 1533). The engravings of all these artists are very valuable, not only from their scarceness, and as illustrating the early history and progress of the art, but as exemplifying many high qualities that have never been surpassed in later times. The most of them were painters, and engraved their own works, except Marc Antonio, who engraved chiefly those of Raphael, by whom he was employed, and who occasionally overlooked and directed him. All those engravers, and their immediate followers, executed their works with the graver; but soon after, engravings came to be generally executed by two processes—etching, and cutting with the graver or the dry-point. The works of these early masters are often remarkable for character and expression, as those, for instance, by Mantegna; and for the correctness and high style of the drawing, for which qualities Marc Antonio has never been surpassed; also for finish of the most careful and elaborate kind, which has been carried further by Albert Dürer and Lucas van Leyden than by any other engravers. The styles of these early engravers were cultivated by numerous successors, several of whom followed their masters as closely as they could, while others diverged into something like originality: the chief names are Agostino Veneziano, about 1620; Nicolas Belin da Modena, and Giov. Ghisi, 1630; Luc. Damesz, who died in 1533; Giov. Giac. Caraglio, and Marco da Ravenna, about 1640; Giul. Bonasone, born at Bologna in 1498, died in Rome in 1564; Eneus Vicus, George Vens, Henrid Aldegraf, and Jean Sebast. Böhm, about 1550; Adrian, Charles, William, and John Collert, Adam and George Ghisi, Suter mann, Virgilius Solis, Cornelius Cort, Martin Rota, and others, ranging from the middle to the end of the 16th century. Agost. Caracci, the celebrated painter, executed many spirited engravings. Saenredam, De Bruyn, Galle, Kellerthaller, Alberti, De Goudt, C. de Pass, Sadeler, are names of well-known engravers that enter on the 17th century. Henry Goltzius is noted for the number and variety of his works, and his imitations of the styles of the older masters. In the plates of engravers towards the middle of the 17th, and beginning of the 18th c., a large proportion of the work consists of etching, the graver being chiefly used for deepening and clearing up the etching. This arose from the manner of working being well adapted for rendering the style of the painters of that period, whose works were distinguished for freedom of execution or touch, and clear-

ness and transparency. The most noted engravers of this period were the Vischers, who flourished between 1610 and 1650, and engraved many of Berghem's pictures; Bolswert, 1620; Lucas Vosterman the elder, 1630; Suyderhoef, about 1640. These engravers rendered many of the works of Rubens in a very spirited manner. Coryn Boel—whose engravings from Teniers are in some respects superior even to La Bas—Troyen, and Van Kessel, are worthy contemporaries.

In the age of Louis XIV., a race of engravers of portraits arose, who carried execution with the graver almost to perfection. The works of the artists they engraved from were florid in style, with a great display of drapery and lace, and accessories in the backgrounds elaborately executed. Among these engravers the following rank highest: Gerard Edelinck (b. Antwerp 1627, d. Paris 1707)—he was one of the best engravers of the period, and specially patronized by Louis XIV.; Masson (b. 1636, d. 1700); Larmessin (b. 1640, d. 1684); Drevet the elder (b. 1664, d. 1739); Drevet the younger (b. 1697); Gerard Andran (b. 1640, d. 1703). There was a large family of Andrans engravers, but Gerard was the most celebrated, indeed, he was one of the best of the French engravers. Among engravers of talent in England may be mentioned Robert Walker (b. 1572); William Faithorne (b. London between 1620 and 1630, d. 1694) executed many excellent engravings of portraits; George Vertue (b. London 1684, d. 1756), a good engraver, and a man of general information and taste in matters of art; John Smith (b. London 1654, d. 1732) executed in mezzotinto a vast number of interesting portraits. In the 18th c., there were numerous excellent engravers, by whose works the taste for the pictures of the Dutch school of the 17th c. has been widely extended. Two of the most distinguished of these were John Philip le Bas (b. Paris 1708, d. 1782) and John George Wille (b. Königsberg 1717, d. 1808). Their styles are totally dissimilar. Le Bas's plates are chiefly etched, and remarkable for spirit and sharpness of touch and transparency; accordingly, mostly all his works are after painters who excelled in these qualities, particularly Teniers. Wille's engravings, again, are of the most careful and elaborate description, and his best prints are after Gerard Dow, Terburg, Mieris, and Metz—masters distinguished for the high finish of their pictures. He worked with the graver; and his plates are distinguished by the precision and clearness with which the lines are cut. See Henri Bérault's *Engravers of the 18th Century*.

It was about the middle and latter portion of last century that engraving reached its highest point in England. The works of William Hogarth (b. London 1698, d. 1764) are of world-wide celebrity, but that is owing mainly to the excellence and dramatic interest of the pictures from which the engravings are made, though, no doubt, his prints are engraved in a firm clear style, similar to that practiced by the French engravers of the time, several of whom were employed by him. It was sir Robert Strange (b. Orkney 1721, d. London 1792), an engraver of figures, and William Woollet (b. Maidstone 1735, d. London 1785), a landscape-engraver, who imparted to English E. those qualities and characteristics that enable us to claim a style of E. that is national, differing from other styles, and that has arisen and been best carried out in this country. In drawing and form, Strange was rather defective; but he excelled in what engravers call color, or the art of producing, by means of variety of line, a texture or quality that compensates for the want of color, by giving to the E. something of the richness produced by color in a picture. His imitation of the softness and semi-transparency of flesh was particularly successful, and superior to that of the French engravers, whose works, though in most respects admirable, failed in that respect, and had, in the more delicate parts, a hard or metallic look. Woollet treated landscape-engraving in a manner totally new, imparting to it more firmness and decision, by making great use of the graver. His works have more finish and force than former landscape-engravers, but they are in some degree liable to the objection of hardness, in the treatment of foliage in particular. The works of these two engravers have had a marked influence on art, not only in this country, but abroad. The merit of Strange's style was acknowledged on the continent; he was elected a member of the academies of Florence, Bologna, Parma, and Rome. At the end of last century, art had fallen very low on the continent, but a regeneration was beginning; and in Italy, engravers were then arising, such as Volpato and Cunego, who studied and imitated the softness and, technically speaking, fleshiness of texture that distinguished the works of the British engraver; those, again, were followed by Raphael Morghen, Longhi, Mercurii, and others, in Italy; by Boucher Desnoyers, Forster, etc., in France; and by Müller, Keller, Gruner, and numerous other engravers in Germany. By them, engraving has been carried to the highest pitch. Amongst their works, the following are *chefs-d'œuvres*: "The Last Supper," after Da Vinci, by R. Morghen; the "Sposalizia," after Raphael, by Longhi; "La Belle Jardinière," and other works, after Raphael, by Boucher Desnoyers, who has engraved the works of Raphael perhaps on the whole better than any other engraver; "The Madonna de San Sisto," by Müller, and "The Dispute on the Sacrament," after Raphael, of Keller. No engravings executed in this country come up to the works of these last-named masters, who have engraved works of a higher class than the majority of those done by Strange, while the drawing and general treatment of their works are in a purer and more correct style. However, the engravings of Burnet, Raimbach, Stewart, and others after Wilkie and contemporary British painters, deservedly held the highest place among works of the class to which they belong, and betoken clearly the great influ-

ence which Strange exercised on their style. At present, few figure-subjects are executed in the line-manner, and that art has certainly fallen in this country. This may be accounted for, perhaps, by the great use made of mechanical appliances, in portions of the work, to save time, and by the preference shown for mezzotinto-engraving as practiced at present, that is, with a mixture of lining or stippling. The greater number of Landseer's works have been engraved in that way, and it is now adopted for rendering the works of John Phillip and Millais, and the leading artists of the day. Several, however, of Landseer's earlier works have been engraved in the line-manner, particularly his pictures of "Drovers Leaving the Grampians," and "The Watering-place," by Watt, which are capital examples of line-engraving. There is no good modern school of landscape-engraving on the continent; the influence of Woollet was entirely confined to this country, where landscape-engraving, particularly in illustrated works after Turner, has attained great excellence.

Towards the end of last century, mezzotint engraving was practiced in England with great success; arising from its being peculiarly adapted to render effectively the works of sir Joshua Reynolds. M'Ardell, Earlom, Watson, Smith, Valentine Green, and Ward were among the best engravers of his works. The invention of this process is generally given to prince Rupert, others ascribe it to Dr. Wren, 1662, and state that prince Rupert merely improved on the invention. It has been practiced very generally from the time of its invention, but attained its highest position in sir Joshua's time; and it is very successfully carried out now, in an altered manner, additional force being aimed at, by means of stippling and etching. It is well calculated for producing broad effects: Turner's *Liber Studiorum*, and the landscapes after Constable, are admirable examples of its capabilities in this way; the effect in Turner's plates, however, is heightened by etching.

The nineteenth century has produced some of the most thoroughly artistic work in line engraving, both in figure and in landscape. Its characteristics, in comparison with the work of other centuries, are chiefly a more thorough and delicate rendering of local colors, light and shade, and texture. The older engravers could draw as correctly as the modern; but they either neglected these elements or admitted them sparingly, as opposed to the spirit of their art. If you look at a modern engraving from Landseer, you will see the blackness of a gentleman's boot (local color), the soft roughness of his coat (texture), and the exact value in light and dark of his face and costume against the cloudy sky. Nay, more, you will find every sparkle on bit, boot, and stirrup. Modern painting pays more attention to texture and *chiaroscuro* than classical painting did, so engraving has followed in the same directions; but there is a certain sameness in pure line engraving which is more favorable to some forms and textures than to others. This sameness of line engraving, and its costliness, have led to the adoption of mixed methods, which are extremely prevalent in modern commercial prints from popular artists. In the well-known prints from Rosa Bonheur, for example, by T. Landseer, H. T. Ryall, and C. G. Lewis, the tone of the sky is produced by machine-ruling, and so is much under tone in the landscape; the fur of the animals is all etched, and so are the foreground plants, the real burin work being used sparingly where most favorable to texture. Even in the exquisite engravings after Turner, by Cooke, Goodall, Wallis, Miller, Wilmore, and others, who reached a degree of delicacy in light and shade far surpassing the work of the old masters, the engravers have recourse to etching, finishing with the burin and dry-point. Turner's name may be added to those of Raphael, Rubens, and Claude in the list of painters who have had a special influence upon engraving. The specialty of Turner's influence was in the direction of delicacy of tone. In this respect the Turner vignettes to Rogers' poems were a high-water mark of human attainment, not likely to be surpassed.

Pure line engraving is still practiced by a few artists in England and France. In France, the lovers of line engraving have endeavored to keep it alive by organizing themselves into a society for its encouragement. The most recent direction of the art, in the works of Ferdinand Gaillard, is a return to studied outline, but in combination with the most elaborate modeling. In his "St. Sebastian" the outline is studied and marked with careful firmness throughout, and the modeling is thoroughly worked out in minute touches and fine lines, giving powerful relief without any but the most delicate *chiaroscuro*.

To prepare a plate for etching, it is first covered with etching-ground, a composition which resists acid. A ground is to be of a quality so adhesive that it will not quit the copper when a small quantity is left isolated between the lines, yet not so adhesive that the etching point cannot easily and entirely remove it; at the same time a good ground will be hard enough to bear the hand upon it, or a sheet of paper, yet not so hard as to be brittle. The plate being grounded, its back and edges are protected from the acid by Japan varnish, which soon dries; then the drawing is traced upon it. The best way of tracing a drawing is to use sheet gelatine, which is employed as follows: The gelatine is laid upon the drawing, which its transparency allows you to see perfectly, and you trace the lines by scratching the smooth surface with a sharp point. You then fill these scratches with fine black-lead in powder, rubbing it in with the finger; turn the tracing with its face to the plate, and rub the back of it with a burnisher. The black-lead from the scratches adheres to the etching-ground, and shows upon it as pale gray,

much more visible than anything else which you can use for tracing. Then comes the work of the etching-needle, which is merely a piece of steel sharpened more or less. Turner used a prong of an old steel fork, which did as well as anything; but neater etching-needles are sold by artists' color-makers. The needle removes the acid and lays the copper bare. Some artists sharpen their needles so as to present a cutting edge, which, when used sideways, scrapes away a broad line; and many etchers use needles of various degrees of sharpness to get thicker or thinner lines. It may be well to observe, in connection with this part of the subject, that while thick lines agree perfectly well with the nature of wood-cut, they are very apt to give an unpleasant heaviness to plate engraving of all kinds, whilst thin lines have generally a clear and agreeable appearance in plate engraving. Nevertheless, lines of moderate thickness are used effectively in etching when covered with fine shading, and very thick lines indeed were employed with good results by Turner when he intended to cover them with mezzotint and to print in brown ink, because their thickness was essential to prevent them from being overwhelmed by the mezzotint, and the brown ink made them print less heavily than the black. Etchers differ in opinion as to whether the needle ought to scratch the copper or simply to glide upon its surface. A gliding needle is much more free, and therefore communicates a greater appearance of freedom to the etching; but it has the inconvenience that the etching-ground may not always be entirely removed, and then the lines may be defective from insufficient biting. A scratch needle, on the other hand, is free from this serious inconvenience; but it must not scratch irregularly so as to engrave lines of various depth. The biting in former times was generally done with a mixture of nitrous acid and water, in equal proportions; but in the present day a Dutch mordant is much used, which is composed as follows: Hydrochloric acid, 100 grammes; chlorate of potash, 20 grammes; water, 880 grammes. To make it, heat the water, add the chlorate of potash, wait until it is entirely dissolved, then add the acid. The nitrous mordant acts rapidly, and causes ebullition; the Dutch mordant acts slowly, and causes no ebullition. The nitrous mordant widens the lines; the Dutch mordant bites in depth, and does not widen the lines to any perceptible degree. The time required for both depends upon temperature. A mordant bites slowly when cold, and more and more rapidly when heated. To obviate irregularity caused by difference of temperature, a good plan is to heat the Dutch mordant artificially to 95° F. by lamps under the bath, for which a photographer's porcelain tray is most convenient, and to keep it steadily to that temperature; the result may be counted upon; but whatever the temperature fixed upon, the result will be regular if the temperature be regular. To get different degrees of biting on the same plate, the lines which are to be pale are "stopped out" by being painted over with Japan varnish, or with etching-ground dissolved in oil of lavender, the darkest lines being reserved to the last, as they have to bite longest. When the acid has done its work properly, the lines are bitten in such various degrees of depth that they will print with the degree of blackness required; but if some parts of the subject require to be made paler, they can be lowered by rubbing them with charcoal and olive oil, and if they have to be made deeper, they can be re-bitten or covered with added shading. Re-biting is done with the roller above mentioned, which is now charged very lightly with paste, and rolled over the copper with no pressure but its own weight, so as to cover the smooth surface, but not to fill up any of the lines. The oil of lavender is then expelled as before by gently heating the plate, but it is not smoked. The lines which require re-biting may now be re-bitten, and the others preserved against the action of the acid by stopping out. These are a few of the most essential technical points in etching, but there are many matters of detail for which the reader is referred to the special works on the subject. During the last twenty years there has been a great revival of etching as an independent art. The comparative rapidity of the process, and the ease with which it imitates the manner of painters, have caused it to be now very generally preferred to line engraving by publishers for the transcription of all pictures except those belonging to a severe and classical style of art. See Hamerton's *The Etcher's Handbook* (London, 1871), and *Etching and Etchers* (London, 1876); Bishop's *The Etcher's Guide* (Phila., 1879); Lalanne's *A Treatise on Etching* (Boston, 1885).

Aquatint may be effectively used in combination with line-etching, and still more harmoniously with soft-ground etching in which the line imitates that of the lead pencil. Of all kinds of engraving, mezzotint comes nearest to nature, though it is far from being the best as a means of artistic expression. Copper, steel, and zinc are the metals chiefly used in engraving. The use of copper is largely increased of late, as the copper is now coated with steel by electrotype process, which enables it to resist printing almost indefinitely, and the steel can be removed at pleasure. Zinc is similarly coated with copper, and is sometimes used for small editions. See WOOD ENGRAVING.

Etching has been already described as a part of the process of E.; but as practiced by painters, it is classed as a distinct art. The plate is prepared with a ground, and corroded in the same way; but the treatment is more free. Not being tied to the task of literally copying or translating the idea of another, like the engraver, the painter has scope to impart a spirit to his work peculiarly suggestive of what he intends to embody; his idea is represented directly, and not at second-hand, as it were. The etchings of Rembrandt, Paul Potter, Karl du Jardin, Adrian Vandevelde, Teniers, Ostade, Berg-

hem, Backhuysen, Van Dyck, Claude, Salvator Rosa, Canaletti, and other painters, are very highly valued, as conveying more completely the feeling of the painter than the best engravings. Etching was more practiced by the old than by modern painters; yet Wilkie, Landseer, and other modern artists, have etched various plates, remarkable for character and spirit.

English works on E.—*Sculpture, or the History and Art of Chalcography and Engraving on Copper*, by John Evelyn (Lond. 12mo, 1663; 8vo, 1755); *The Art of Engraving and Etching, with the Way of Printing Copper-plates*, by M. Faithorne (Lond. 1702); *Sculptura Historico-technica, or the History and Art of Engraving, extracted from Baldinucci Florent, Le Compt, Faithorne, the Abecadario Pittorico, and other authors* (Lond. 4to, 1747, 1766, and 1770); *An Essay upon Prints*, by Gilpin (Lond. 8vo, 1767, 1768, and 1781); Strutt's *Biographical Dictionary of Engravers* (2 vols., 4to, Lond. 1785); Landseer's *Lectures on Engraving* (8vo, Lond. 1806); *An Inquiry into the Origin and Early History of Engraving upon Copper and on Wood*, by Otley (1816); Hamerton's *Graphic Arts* (1882).

Of late years, many inventions have been introduced, having for their object to supersede the slow and laborious manual operations of E. by means of machinery and other appliances. It is, however, to business and ornamental purposes that they are chiefly applicable, and not to the production of artistic work of the kind treated of in this article. The subject will be noticed under MACHINE-ENGRAVING, MEDAL, GLASS, etc. With regard to the reproduction of plates, and other applications of galvanic electricity to E., see GALVANISM AND MAGNETO-ELECTRICITY. See also PHOTOGRAPHY AND PHOTOGRAPHIC PROCESSES.

ENGRAVINGS, PROPERTY IN. The copyright law adopted by the United States in 1891 includes in the list of articles to which the right of copyright may attach, engravings, cuts, prints, photographs and negatives thereof, as well as books, maps, and the like. Proprietorship, therefore, in any engraving may be retained by the process of depositing before publication with the Librarian of Congress a copy of the title of the engraving with a description thereof and delivering to the same person after publication two copies of the work. As in other cases, the copyright runs for twenty-eight years, and it may be renewed by the artist or his widow or children for a further term of fourteen years. Engravings judged to be immoral or obscene are not entitled to copyright privilege. In England a comparatively recent statute defines the acts relating to copyright in engraving to include lithographs or the products of any mechanical process by which prints or impressions of drawings or designs are capable of being multiplied indefinitely; and this definition has been held to include photographs. See COPYRIGHT.

ENGROSSING A DEED. See INGROSSING.

ENGROSSING AND REGRATING. An engrosser, regrater, or forestaller, is a person who buys grain, flesh, fish, or other articles of food, with the intention of selling them again at an enhanced price, either in the same fair or market, or in another in the neighborhood, or who purchases or contracts for corn while still in the field. These practices were regarded as criminal in most countries, before the laws by which trade is regulated were properly understood. In England, they were forbidden by various statutes, from the time of Edward VI. to that of queen Anne. These statutes were repealed by 12 Geo. III. c. 71, on the preamble, that it hath been found by experience, that the restraints laid upon the dealing in corn, meal, flour, cattle, and sundry other sorts of victuals, by preventing a free trade in the said commodities, have a tendency to discourage the growth, and to enhance the price of the same. It was found, however, that engrossing was not only a statutory but a common law offense, and a prosecution for it in the latter character actually took place in the present century. The act 7 and 8 Vict. c. 24, for abolishing the offenses of forestalling, regrating, and engrossing, was consequently passed. Besides declaring that the several offenses of badgering, engrossing, forestalling, and regrating be utterly taken away and abolished, and that no information or prosecution shall lie either at common law or by virtue of any statute, either in England, Scotland, or Ireland, this statute repeals a whole host of earlier enactments in restraint of trade, which had been omitted in the statute in the time of George III., above referred to. The rubrics of these enactments give a curious picture not only of the trading errors, but in many other respects of the obsolete customs of our ancestors. The first, for example (51 Henry III.), is called a "statute of the pillory and tumbrel, and of the assize of bread and ale." Then there is an act passed in several reigns which provides for the punishment of "a butcher or cook that buyeth flesh of Jews, and selleth the same to Christians."

Notwithstanding the doctrine of the Scottish law, that statutes may be repealed by mere desuetude, it was thought safer to include the Scottish statutes to the same effect. The earliest is 1503, c. 38, and the latest 1661, c. 280.

The statute 6 and 7 Vict. c. 24, does not apply to the spreading of false rumors, with the intent to enhance or decry the price of merchandise, or preventing goods from being brought to market by force or threats, which continue to be punishable as if that act had not been made.

ENGUE'RA, a t. of Spain, in the province of Valencia, 35 m. s.w. of the town of that name. It is poorly built, and has narrow and irregular streets. It has manufactures of linen and woolen goods, and some trade in cattle and agricultural produce. Pop. '87, 6256.

ENGUICHÉ. A hunting-horn, the rim around the mouth of which is of a different color from the horn itself, is said heraldically to be enguiché, of the color in question.

ENHARMONIC, a term applied in music when the name of a note is changed without any sensible difference of sound, such as C \sharp and D \flat , F \sharp and G \flat . Correctly speaking, there is, or ought to be, a difference; but on keyed instruments, such as the organ and pianoforte, there can be none, as the same key serves for both sharp and flat, while with a just equal temperament the ear is in no way offended. In harmony, the principal seat of enharmonic change is in the chord of the diminished seventh, which, by a change of the notes, may be treated fundamentally in four different ways, without any sensible difference in the intonation.

ENKHUI'SEN, a fortified t. and seaport of the Netherlands, in the province of North Holland, is situated on the western shore of the Zuider Zee, about 30 m. n.e. of Amsterdam. It is built with great regularity, and is of a circular form. The most important public building is an elegant town-house, with a lofty tower. In the sixteenth and seventeenth centuries it was a very important commercial centre with a large population, of whom many were engaged in the herring fisheries. The chief industries are ship and boat-building, rope-spinning, sail-making, refining salt, brewing, etc. There is an export trade in butter, cheese, corn, timber, cattle, and fish. Several vessels are engaged in the herring-fishing. Pop. '89, 5,780.

ENLIGHTENED DOCTOR. See LULLY, RAYMOND.

ENLISTMENT IN THE ARMY is superintended by the recruiting service, the chief of which is stationed in New York. The recruiting service is both general and special—general when performed by officers selected and detached for such duty, and special when it concerns departments and regiments, or particular military organizations. The adjutant-general details the field officers to superintend the service and command the recruiting depots, and announces in orders the number of the company officers to be furnished for it by each regiment.

Applicants for enlistment must be between the ages of eighteen and thirty-five years, unmarried, of good character and habits, able-bodied, and free from disease. No applicants are enlisted who cannot intelligibly converse in English and fully understand orders and instructions given in that language.

Applicants are required to satisfy the recruiting officer regarding age and character, and should be prepared to furnish the necessary evidence. *A minor can be enlisted only with the written consent of his parents or a legally appointed guardian, and when his physical development is exceptionally good and presents many characteristics of maturity.*

For infantry and artillery the height must be not less than five feet four inches, and weight not less than one hundred and twenty-eight (128) pounds, and not more than one hundred and ninety (190) pounds.

For cavalry the height must not be less than five feet four inches, and not more than five feet ten inches, and weight not to exceed one hundred and sixty-five (165) pounds. The maximum age for cavalry recruits upon original enlistment is fixed at thirty years.

The term of service is five years. Under the law a soldier in his first enlistment, after having served one year, can purchase his discharge for \$120, with a reduction of \$5 in the purchase price for every subsequent month until he completes three years' service, when, if he has served honestly and faithfully, he is entitled to a furlough for three months, with the privilege of discharge at the expiration of the furlough. All soldiers, in addition to their pay, receive rations, clothing, bedding, medicines and medical attendance.

The following is the rate of pay as now established :

| GRADE. | Pay per Month. |
|---|----------------|
| Hospital Steward..... | \$45 |
| Acting Hospital Steward..... | 25 |
| Sergeants of Post Non-commissioned Staff..... | 34 |
| Sergeant Major—Cavalry, Artillery, and Infantry..... | 23 |
| Regimental Quartermaster Sergeant—Cavalry, Artillery, and Infantry..... | 23 |
| Principal Musician—Artillery and Infantry..... | 22 |
| Chief Trumpeter of Cavalry..... | 22 |
| Saddler Sergeant—Cavalry..... | 22 |
| First Sergeant of a Company—Cavalry, Artillery, and Infantry..... | 22 |
| Sergeants—Cavalry, Artillery, and Infantry..... | 17 |
| Corporals—Cavalry, Artillery, and Infantry..... | 15 |
| Farriers and Blacksmiths—Cavalry..... | 15 |
| Saddlers—Cavalry..... | 15 |
| Field Musicians—Cavalry, Artillery, and Infantry..... | 13 |
| Privates—Cavalry, Artillery, Infantry, and Hospital Corps..... | 13 |

From the first year's pay \$4 per month is retained, which, together with \$1 per month for the third year of enlistment, \$2 per month for the fourth year, and \$3 per month for

the fifth year, in addition to the rates above enumerated, will be paid to the soldier upon discharge, provided he has served honestly and faithfully. The sums thus retained will be treated as deposits, upon which interest, at the rate of four per cent. per annum, will be paid from the end of the year of the soldier's enlistment in which they have accrued.

The soldier can deposit his savings in sums not less than \$5 with any army paymaster, and for any sums not less than \$5 so deposited for the period of six months or longer, the soldier, on his final discharge, will be paid interest at the rate of four per cent. per annum. These deposits are non-forfeitable except for desertion.

For soldiers who have become infirm during 20 years' service, or who have been discharged for wounds received or sickness brought on in service, a comfortable home is maintained in the city of Washington. Twelve and a half cents per month is deducted from the soldiers' pay to be applied toward the support of the home. After 30 years' service enlisted men are entitled to retire upon three-fourths of the monthly pay in the grade they held when retired, with commutation for allowances of clothing and subsistence.

ENLISTMENTS IN THE NAVY are made at naval rendezvous, on board receiving ships, and on board cruising vessels, and are usually for a term of three years. Enlistments for duty on board receiving ships, coast survey vessels, fish commission vessels, at the Naval Academy, and other naval stations are for special service for the term of one year. Enlistments on board vessels in foreign waters are for the cruise of the vessel only, and no person can be enlisted in the naval service unless the commanding and medical officers both pronounce favorably as to his fitness. No person under the age of fourteen, no insane nor intoxicated person, no person known to have committed an infamous crime, and no deserter from the naval or military service of the United States can be elected. Minors cannot be enlisted without the consent of their parents or guardians. The shipping articles are read to every person about enlisting, in order that he may clearly understand what he is doing. General service men can only be enlisted in the following ratings: Seamen, ordinary seamen, landsmen, machinists, boilermakers, first-class firemen, second-class firemen, coalheavers, and such petty officers as are entitled to be enlisted in their ratings from having received three consecutive good conduct badges, or holding a seaman gunner's certificate. The master-at-arms, ship's and engineer's yeomen, will be enlisted as landsmen and rated. Bandsmen, officers' stewards, cooks, and attendants are enlisted for the cruise only.

ENLISTMENT DURING THE CIVIL WAR. The following is a complete list of the various "calls" for troops by the United States government during the civil war:

| Date of Call. | Number of Men. | Term of Service. | Number Obtained. |
|---------------------|----------------|-------------------|------------------|
| April 15, 1861..... | 75,000 | 3 months | 91,816 |
| May 3, 1861..... | 500,000 | 6 mo.-1-2-3 years | 700,080 |
| July 2, 1862..... | 300,000 | 3 years | 421,465 |
| Aug. 4, 1862..... | 300,000 | 9 months | 87,588 |
| Oct. 17, 1863..... | 300,000 | 3 years | 317,092 |
| Feb. 1, 1864..... | 200,000 | 3 years } | |
| Mar. 14, 1864..... | 200,000 | 3 years | 259,515 |
| July 18, 1864..... | 500,000 | 1-2-3-4 years | 385,163 |
| Dec. 19, 1864..... | 300,000 | 1-2-3-4 years | 211,752 |

There were other calls for 30 and 100 days' men. The aggregate quota called for was 2,763,670; total obtained, 2,678,967. By act of congress Mar. 3, 1863, called the "conscription act," the president was authorized to draft troops. The act provided for an enrollment, a draft, the reception of substitutes, and arrest of deserters. About 3,000,000 men between the ages of 20 and 45 were enrolled. The calls from Oct. 17, 1863, were orders for drafts. But probably not more than 50,000 drafted men performed personal service. Substitutes were obtained. "The substitute fund" of the government, consisting of money paid in as a release from service, and which was used as a "bounty fund" for volunteers, amounted to \$25,902,029.

ENMANCHÉ, or EMANCHÉ. See MANCHE.

ENNEAN'DRIA, is the ninth class of plants in the Linnæan system, so called because the flowers have nine stamens. It is a small class, and the Linnæan classification being now generally superseded, the term is not often used.

ENNEMOSER, JOSEPH, known as a medico-philosophic writer, was b. 15th Nov., 1787, at Hintersee, in the Tyrol, and commenced his academic studies at Innsbruck in 1806. On the rising of the Tyrolese against the French in 1809, E. followed Andreas Hofer as his secretary, and honorably distinguished himself in battle on several occasions. At the close of the war, he went to Erlangen, and subsequently to Vienna, for the purpose of concluding his studies. Here, however, he experienced the greatest difficulty in procuring the means of subsistence, but fortunately fell in with a merchant from Altona, in whose company he traveled for some time. When Napoleon declared war against Russia in 1812, E. was despatched to England, to solicit aid for the Tyrolese in their meditated insurrection against the French domination. He was afterwards appointed by Friedrich Wilhelm III., king of Prussia, an officer in a regiment of volunteers, and soon gathered about him a company of Tyrolese marksmen, who were

of great service during the campaigns of 1813 and 1814. After the peace of Paris, E. went to Berlin, where he finished his curriculum, and in 1816, took his degree of doctor of medicine. In 1819, he was made professor of medicine at the new university of Bonn, where he lectured on anthropology, physical therapeutics, and pathology. A love of his native country induced him to settle as a physician in Innsbruck, but in 1841 he went to Munich, where he obtained a great reputation by the application of magnetism as a curative power. Among his writings may be mentioned, *Der Magnetismus in seiner geschichtlichen Entwicklung* (Leip. 1819), which is reckoned his principal work; *Historisch-psychologische Untersuchungen über den Ursprung und das Wesen der Menschlichen Seele* (Bonn, 1824); *Anthropologische Ansichten zur bessern Kenntniss des Menschen* (Bonn, 1828); *Der Magnetismus im Verhältniss zur Natur und Religion* (Stuttg. 1842); *Der Geist des Menschen in der Natur* (Stuttg. 1849); *Was ist die Cholera* (2d edit., Stuttg. 1850); and *Anleitung zur Mesmer'schen Praxis* (Stuttg. 1852). He died in 1854.

ENNIS, a municipal borough, chief t. of co. Clare, Ireland, on the Fergus, 20 m. w.n.w. of Limerick, is a neat town, with some good houses. Pop. '91, 6500. Till 1885 it returned one member to parliament. It has a Roman Catholic college, a Roman Catholic cathedral, the ruins of a monastery founded in 1240 by O'Brien, prince of Thomond. Near the town is Ennis college, founded by Erasmus Smith. E. has a valuable limestone quarry, large flour mills, and some trade in grain.

ENNISCORTHY, a market t. in the middle of Wexford co., Ireland, on a rising ground on the Slaney, 14 m. n.n.w. of Wexford. The Slaney is here tidal and navigable for barges, and flows through a fertile and beautiful valley. Pop. '91, 5,648.

ENNISKILLEN, a municipal and till 1885 a parliamentary borough, chief town of co. Fermanagh, Ireland, about 75 m. w.s.w. of Belfast, is beautifully situated on the Erne; the greater portion on an isle in the river between the upper and lower loughs Erne. It consists mainly of one undulating street running e. and w. Around are richly cultivated eminences and many fine mansions. It has various manufactories including tanneries, cutlery works, and straw hat works and markets for butter, pork, and flax. Pop. '91, 5,570. E. received its first charter in 1613. It is famous for the victory, in 1689, of the troops of William III., under lord Hamilton, over a superior force of James II., under lord Galmoy.

ENNIVS, QUINTUS, an early Roman poet, the father of the Roman Epos, was b. at Rudia, in Calabria, about 240 years before the Christian era, and was probably of Greek extraction. He is said to have served in the wars, and to have risen to the rank of a centurion. In Sardinia, he became acquainted with Cato the elder, and returned with him to Rome, when about the age of 38. Here he gained for himself the friendship of the most eminent men, among others that of Scipio Africanus the elder, and attained (what was then exceedingly rare in the case of an alien) to the rank of a Roman citizen. He supported himself in a decent but humble manner by instructing some young Romans of distinguished families in the Greek language and literature, his accurate knowledge of which explains the influence he had on the development of the Latin tongue. He died when he had attained the age of 70, or about 169 B.C. His remains were interred in the tomb of the Scipios, and his bust was placed among those of that great family. E. has tried his powers in almost every species of poetry, and although his language and versification are rough and unpolished, these defects are fully compensated by the energy of his expressions, and the fire of his poetry. His poems were highly esteemed by Cicero, Horace, and Virgil: the last, indeed, frequently introduces whole lines from the poetry of E. into his own compositions. His memory seems to have been lovingly cherished by his countrymen; *Noster Ennius*, "Our Ennius," they used to call him. Of his tragedies, comedies, satires, and particularly of his *Annales*, an epos in 18 books, only fragments are still extant. What adds to our regret is, that it is believed his whole works were extant as late as the 13th c. (A. G. Cramer, *Hauschronick*). The fragments have been collected and edited by various scholars, among others by Hessel (Amst. 1707). The fragments of the *Annales* have been edited by J. Vahlen (Berlin, 1886). Compare Hoch, *De Ennianorum Annalium Fragmentis* (Bonn, 1839). The few fragments of his dramas that have come down to us were collected by Ribbeck in his *Scenica Romanorum Poesis Fragmenta* (2 vols. 1871-73).

ENNS, a river of Austria, rises at the northern base of a branch of the Noric Alps in the crownland of Salzburg, 12 m. s. of Radstadt. It first flows n. to Radstadt, then n.e. to Hieflau, after which it proceeds in a general direction n.n.w., passes Steyer, and joins the Danube 11 m. below the town of Linz, after a course of about 120 miles. Its chief affluents are the Salza and the Steyer. For the last 15 m. of its course, the E. forms the boundary between Upper Austria (Ober der Enns) and Lower Austria (Unter der Enns). The scenery on the banks of the E. is in general bold and romantic, as it flows, for the most part, between parallel mountain-chains, which are lofty and precipitous. In its lower course, it becomes navigable, but it is chiefly important from the valuable water-power which it supplies.

ENNS, or ENS, a t. in Austria, on the river Enns, near its junction with the Danube; pop. '90, 4,674. It has iron and steel manufactures. It stands on the site of a Roman station, Lauriacum, where in 304 Galerius inflicted a cruel persecution upon the Chris-

tians. The walls of the town were built with the ransom money paid for Richard I. of England.

ENNUI (Fr. *ennuyer*, to annoy). The English equivalent of this expression, as nearly as it can be rendered, is "listlessness," "dullness." It denotes a wearied state of mind due to the want of an object of interest, or to enforced attention to something devoid of interest; the state of being bored. In common parlance, it denotes a listlessness found among ultra-fashionable people caused by an excess of pleasure.

ENOCH, the name of two different individuals in Scripture.—1. The eldest son of Cain, who built a city which was called after his name.—2. The son of Jared, and father of Methuselah. A peculiarly mysterious interest attaches to him on account of the supernatural manner in which his earthly career terminated. We are told by the writer of Genesis, that E. "walked with God 300 years . . . and he was not; for God took him." What the statement "he was not" signified to the later Jews, is explained by the writer of the Epistle to the Hebrews: "Enoch was translated that he should not see death." E. and Elijah are the only human beings on record who did not require to discharge the debt which mortals owe to nature. It may naturally be supposed that E. was a character on whom the extravagant fancy of the later Jews would fasten with unusual pleasure. As they came more and more into contact with Grecian and other culture, they felt the necessity of linking on the arts and sciences of Gentile nations to their own history, if they would continue to preserve that feeling of supremacy which was so dear to their pride as the chosen people. Hence, E. appears as the inventor of writing, arithmetic, astronomy, etc., and is affirmed to have filled 300 books with the revelations which he received, the number 300 being obviously suggested by the number of years during which he is said to have walked with God.

ENOCH, Book of. This book, from which, curiously enough, St. Jude quotes as if it were history, shows how richly mythical the history of the mysterious antediluvian E. had become! It was probably written originally in Aramaic, by a native of Palestine, in the 2d. c. B.C. The precise date is not known. At subsequent periods, it would seem to have been enlarged by additions and interpolations. It is divided into five parts; and the *first* discourses of such subjects as the fall of the angels, and the journey of E. through the earth and through Paradise in the company of an angel, by whom he is initiated into the secrets of nature, etc.; the *second* contains E.'s account of what was revealed to him concerning the heavenly or spiritual region; the *third* treats of astronomy and the phenomena of the seasons; the *fourth* represents E. beholding in prophetic vision the course of Divine Providence till the coming of the Messiah; and the *last* consists of exhortations based on what has preceded. The book was current in the primitive church, and was quoted by the fathers, but was lost sight of by Christian writers about the close of the 8th c., so that until last century it was only known by extracts. Fortunately, however, the traveler Bruce discovered in Abyssinia three complete MSS. of the work, which he brought to England in 1773. These MSS. proved to be an Ethiopic version made from the Greek one, in use among the fathers, as was evident from the coincidence of language. The Ethiopic version did not appear till 1838 when it was published by archbishop Lawrence. An English translation, however, by the same writer, had appeared in 1821, which passed through three editions, and formed the basis of the German edition of Hoffmann (Jena, 1833-1838). In 1840, Gfrörer published a Latin translation of the work; but by far the best edition is that of Dr. A. Dillmann, who in 1851 published the Ethiopic text from five MSS., and in 1853, a German translation, with an introduction and commentary, which has recently turned the attention of many German scholars to the subject. See Schodde's Eng. trans. (1882).

ENOMOTO KAMAJIRO, one of the Japanese young men of promise sent by the tycoon in 1862 to study in Europe. In Holland, E. obtained a solid training in science and naval practice. Returning to Japan in 1867, he was put in command of the *Kaiyo Maru*, a 26-gun vessel of 400-horse power. The revolution breaking out, and the tycoon being overthrown, E. endeavored to obtain from the United States minister, Gen. Van Valkenburgh, the possession of the *Stonewall*, formerly a confederate iron-clad ram built in England, captured by the United States forces, and purchased and paid for by the tycoon's government. Being unsuccessful, E. left the anchorage near Yedo, with the seven war vessels under his charge, and sailed to Hakodadi. Being disowned by his former master, E. declared himself and his forces independent, and set up a republic somewhat after the model of the United States, of which he was elected president. This government continued for several months, but by June, 1869, the land and naval forces of the mikado had reached Yezo, and battles rapidly followed each other at Esashi, Matsumae, and Kikonai. Finally, June 4, the final conflict took place at Hakodadi. The three vessels of E. were opposed to the five flying the mikado's flag, one of which was the iron-clad ram *Stonewall*. A terrific naval battle was kept up during several days, while the land forces were engaged almost continually. The "rebel" fleet and forts were utterly destroyed, chiefly by the iron-clad, and on the 26th, E. and the leaders surrendered. He was kept in prison until 1872, when he was pardoned and given a position in the Kai Takn Shi (department of colonization of Yezo). In 1874, he was made vice-admiral in the imperial navy, and sent to Russia as minister plenipotentiary, negotiating the treaty by which Russia gave to Japan the Kurile islands. In 1890 he was made minister of state for communications.

ENOS (anciently, *Ænos*), an ancient t. and seaport of European Turkey, in the province of Adrianople, is situated on a rocky isthmus at the mouth of a gulf of the same name, about 35 m. w.n.w. of Gallipoli. It is the port of Adrianople, and has some trade in wool, camels' hair, cotton, leather, silk, etc. Its harbor is commodious, but so shallow, from being choked up with sand, that it admits only small vessels. Pop. 6,000, principally Greeks. The gulf of Enos is about $2\frac{1}{2}$ m. wide at the entrance, extends into the country for about 14 m., and is on an average 5 m. broad.

The town of E. is very ancient. Virgil mentions it (*Æn.* iii. 18) as being one of the towns founded by Æneas, after the sack of Troy; and Homer also attests its antiquity by alluding to it in his great poem (*Il.* iv. 519).

ENOS, ROGER, 1729–1808; an officer in Arnold's expedition to Quebec, but sent back with his troops for lack of provisions. He was afterwards an eminent citizen of Vermont.

EN RAPPORT (Fr.). This phrase is rendered, "in agreement with," "in harmony with." It refers especially to a peculiarly sympathetic relation existing between parties, and may be due to ordinary or mesmeric influence. This expression is in general use in ordinary life, but has a special significance among spiritualists to denote the relations existing between the medium and the subject.

ENRIQUEZ, GOMEZ ANTONIO (properly, **ENRIQUEZ DE PAZ**), a Spanish poet, the son of a baptized Portuguese Jew, was b. at Segovia early in the 17th century. He entered the army in his 20th year, and rose to the rank of capt.; but in 1636, had to flee the country, to escape the persecution of the Inquisition, which suspected him of a secret leaning to the creed of his father. E. settled at Amsterdam, and latterly professed the Jewish faith; in consequence of which, he was burned in effigy by the pious Catholics of Seville, 14th April, 1660. The date of his death is not known. During his residence in Spain, E. had considerable reputation as a dramatic poet. According to his own account, he wrote 22 comedies, which met with great success on the stage, in consequence of which, several of them passed as Calderon's. *La prudente Abigail*; *Engañar para reinar*; *Celos no ofenden al sol*; and *A lo que obligan los celos*, were published under the name of Fernando de Zárate. E.'s comedies show him to have possessed much inventiveness, but in other respects they deserve little praise. Among his other writings are *Las Academias morales* (Rouen, 1642), containing some fine elegiac verse; *La Culpa del primer peregrino* (Rouen, 1644), a mystico-theologic poem; *El siglo Pitagórico* (Rouen, 1647), a series of satirical portraits partly in prose and partly in verse; and *El Samson Nazareno* (Rouen, 1656), an abortive epic. For a notice of E. and his writings, see Ticknor's *History of Spanish Literature*.

ENROLLMENT, entry upon a register or record. In English law it is the registering or entering of any lawful act, as a recognizance, deed of bargain and sale, and the like, on the rolls of chancery, king's bench, common pleas, or exchequer, or by the clerk of the peace on the records of the court of quarter sessions. In the United States the term is employed with reference to vessels engaged in the coasting and home trade, which are *enrolled*, while those employed in foreign trade are *registered*; and the words *registration* and *enrollment* are used to distinguish the certificates to those two classes of vessels. Enrollment applies only to the vessels engaged in domestic commerce, and in voyages along the coast or in inland waters.

ENSCHEDÉ, a t. in the Netherlands, province of Overijssel, lies about 4 m. from the Hanoverian boundary, and 30 m. w.n.w. of Zutphen. Besides fustians and dimities, cottons for export to Java are largely manufactured. Cotton-spinning, bleaching, dyeing, and calendering also employ many of the inhabitants. There are several benevolent institutions, churches of various denominations, a chamber of trade, and grammar-school, in which French, English, and German are taught. In 1889, pop. 7,079.

ENSEMBLE (Fr.), the general effect produced by the whole figures or objects in a picture, the persons and plot of a drama, or the various parts of a musical performance.

ENSIGN was, until 1871, the title of the lowest combatant rank of commissioned officers in the British army, and is derived from their being charged with the duty of carrying the regimental colors or E. (Fr. *enseigne*, Lat. *insigne*). In the hand-to-hand mêlées of the middle ages, the preservation of the colors or standard, as the rallying-point of those fighting under the same leader, was a matter of vital importance, and was only intrusted to the bravest and most trustworthy. The colors were committed to him with imposing ceremony in presence of the assembled regiment, and he had to take an oath to defend them with life and limb, and if need were, to wrap himself in them as a shroud, and devote himself to death. The man who undertook this perilous post received sometimes as much as sixfold the usual pay. It was doubtless in this way that the point of honor arose respecting the colors. History records repeated instances where the oath was kept to the letter. In the modern system of warfare, the regimental colors are seldom exposed to such danger, and the office of E. is of less account.

ENSIGN, in the United States navy, is the national flag. It is also used in the merchant service to designate the country to which the vessel belongs. There is an officer in the navy called ensign, who ranks below master and above midshipman. In the army and the militia an ensign is assigned to each company, his duty being to carry the flag or standard of the company. Sometimes the duty falls to a sergeant.

ENSILAGE, green fodder, preserved for cattle, by a process not unlike that employed in the preparation of sauerkraut. A silo or pit, large or small, is first prepared; usually placed, for convenience of feeding, contiguously to the barn in which cattle are housed. It must be so constructed that the air can be excluded from its contents, and of such form and dimensions as will facilitate their settling into a solid mass, and as, when opened for feeding, will expose to the atmosphere as small a part of the surface as practicable. The construction of a silo 16 to 20 ft. long, 8 ft. wide, and from 15 to 20 ft. deep, is thus described: 12-in. perpendicular walls of hard brick, well laid in cement, with smooth joints. If the ground is sandy or gravelly, the outside of the walls next the earth is covered with a coat of cement, or the walls are filled in behind with clay or clayey earth, to prevent the passage of the air through them. The bottoms are also laid with brick upon the flat in cement. The walls are made so smooth upon their inner sides as to offer no obstacle to the settling and compacting of the food by friction of the sides. The pit may be made either open at the top and covered with a roof, or arched over under ground, with two necks coming up to within one foot of the surface of the ground, through which it is filled. The pit being prepared, the fodder is cut green, when in the best condition, or in bloom, passed immediately through the cutting-machine, to reduce it to uniform short lengths of not more than 1 in., and then deposited and trodden firmly into the pit, sufficient salt being used to render it palatable, but no more. As fermentation—which will commence at once—proceeds, and the mass settles, the cutting and treading in of fresh fodder must be continued from day to day, after an interval of about 36 hours, until the pit is filled and settling has ceased. Then the pit is immediately and thoroughly sealed over the whole top surface of the fodder, by a well-compacted layer of clean fodder, not less than 6 in. thick, excluding the air. Over this layer, some lay planks weighted with heavy stones; others deem this needless. The fodder to be thus treated may be corn, red clover, pearl millet, West India millet, or Guinea corn, green rye, oats, mixed grasses, or any other succulent production of which cattle are fond. Food preserved by this process is greatly relished. It is eaten eagerly and clean, leaf and stalk, without any loss whatever; and stock thus fed exhibit the highest conditions of health and thrift. It is recommended especially for milch cows, as it increases the quantity and improves the quality of milk.

The Greek word *siros*, a pit, and the Spanish word *ensilar*, to store grain in a pit, explains the origin of the word ensilage. Vaults or pits in the ground for the storage of grain are of very early date. In Syria and other parts of the east they are still in use, but it was dried grain that was stored in these early silos. In 1850 the Rev. John Wilson gave a detailed account of the German and East Prussian method of storing green crops in silos. M. Goffart in 1874 stored 250 tons green corn mixed with one fifth of its weight of dry chaff from rye straw. The dimensions of the silos used were—length 12 yds., depth 2 yds. The result was satisfactory, and the process extended rapidly in France. Mr. Morris of Md. and Mr. Mills of N. J. were among the first to try the new process in this country. Mr. Mills, it is said, kept 120 cattle and 12 horses for seven months on the product of 13 acres. Since that time the method has been rapidly extending in the U. S., and seems to be very highly esteemed. A special report was issued on the subject by the U. S. commissioner of agriculture in 1882, and the replies, received from all parts of the country, to the questions asked showed that in the experience of all who had used it, this method of storing food for cattle was successful and economical. It is merely a canning process on a large scale, or doing for the lower animals what has long been done for man—giving them the advantage of a green food in winter. The exclusion of the oxygen of the air, which leads to putrefactive fermentation, is the object to which all the methods tend, and upon which their success depends. The silo of the Vicomte de Chezelles is the largest of which we have any account; its length is 72 yds., width $6\frac{1}{2}$ yds., height above the ground $4\frac{1}{2}$ yds., and its bottom is 4 yds. below the surface. It holds the green crops from 170 acres. In the case of very large silos, they should be partitioned off for convenience in packing. This also prevents exposure of too large a surface of the ensilage to the air while it is being used. Cylindrical forms are highly recommended, and by giving them a sufficient depth much of the weighting can be dispensed with. A silo containing 19,200 cu. ft. will hold about 480 tons. The cost is from four to five dollars per ton when built with stone walls laid in cement. If built above ground, which will serve very well, the walls may be made of two thicknesses of inch boards with sheathing paper between them; the cost of such a silo should not exceed 50 cents a ton. In the case of a very dry soil with good drainage a pit or trench without any wall will suffice. If a simple earthen pit be used more weight must be placed upon it, especially around the edges. In a pit silo the outer portions of the contents are apt to be spoiled, so that in the end it is not economical. Iron has sometimes been used as a material for making the silos. After the silo is filled, weighting it is specially important; this has been done by

means of screws and pulleys. In the U. S. corn is considered the best green crop for storing; its average yield per acre is placed at 20 tons. The crop may be put in from June to October as it reaches the proper stage for cutting; the storage may be carried on in wet as well as dry weather; and in this respect it presents a great advantage, as the farmer runs no risk of losing his crop through a season of rain.

M. Goffart recommends that the pit be filled at the rate of two feet per day. If for any reason the filling has to be stopped, the silo should be covered and weighted till the storing begins again. The cost of filling varies according to circumstances, and no general price can be fixed. A great advantage of Ensilage is that it permits the utilization of a great many green crops that would otherwise be wasted. Salt was at first mixed with the fodder as it was being packed, but is not now much used. As soon as the silo is closed the process of fermentation begins, and a large amount of heat is evolved, due to the vegetable matter undergoing oxidation, which is caused by the oxygen that has not all been forced out. The temperature in some cases rises as high as 60° C. Carbonic acid is produced, and this gas by its pressure keeps out any air that otherwise might enter. The plant cells, when the air has been excluded from them act sluggishly, and do not undergo the destructive decomposition that would take place were air supplied; and by the time that all the oxygen left in the mass has been used up, the substance has become so compact that the air cannot enter, and the cell life continues in a low form till a supply of air is admitted, or till the exposure of the substance to the air, which soon brings decomposition. The heat generated in the first instance is sufficient to destroy the germs that would produce destructive fermentation, and after they are killed none others can penetrate the mass. While the temperature remains high, the process of saccharification goes on, converting some of the carbon compounds into saccharine substance.

The chemical processes that go on in the silo make the substance more digestible, and resemble the change that is supposed to take place in the first stomach of ruminant animals. The effect of the fermentation is to break down the fibrous substance and render it more soluble. The change makes it very palatable to the animals and they seem to prefer it to the green fodder. The analysis of the ensilage compared with that of artificially dried, and field dried Lucerne, shows the following results:

| | Ensilage. | Carefully dried Lucerne. | Field dried Lucerne. |
|---|-----------|-----------------------------|-------------------------|
| Albumenoids..... | 18.35 | 17.00 | 14.94 |
| Fiber | 28.87 | 31.81 | 33.90 |
| Fat, Soluble Carbo-hydrates and Alcohol (if any) } | 38.95 | 43.80 | 44.22 |
| Ash..... | 11.29 | 7.39 | 6.94 |

The acid taste of the ensilage is due to the presence of acetic and lactic acid which are found in small quantities. There is also found a slight trace of alcohol, but not enough to be in the least injurious. As the oxygen left in the mass is used up, the temperature becomes gradually lower, till the ensilage reaches the proper state to be used, generally in three or four months. The material is said to be equal to one third of its weight of the best hay, and its effect on milch cows is like that of turning them into a green pasture. Whether it is good for horses depends upon the green fodder from which the ensilage is made; if that was not suitable for them the ensilage from it will not be. The ration for a cow is 50 or 60 lbs. daily; it has the best effect when fed with a small quantity of dry food. Six tons will keep one cow six months, and a cu. ft. weighs from 40 to 50 lbs., so that the size of a silo to keep a certain number of cows can be readily ascertained. In one experiment seven acres yielded 212 tons of corn ensilage, which kept 35 cows for six months. Mr. Wolcott of Mass. concludes from his experiments that four times as many cows can be kept by using ensilage than by the old plan of dry hay. The ensilage should appear soft, moist, and wholesome, with a slight alcoholic smell somewhat like brewers' grains. It is best to keep it a day out of the pit before using. Care should be taken not to expose the surface of the ensilage to the air any more than can be avoided, and if it can be cut so as to leave a fresh surface each day it is best. There is no trouble about its keeping after the pit is once opened. M. Goffart fed from one of his pits from April to August, the pit remaining open all the time. The material should not be kept for more than a year, as it deteriorates in quality though it has been kept usable for four years.

At the end of June 1884 there were in Great Britain 610 silos, 514 of which were in England. Their total capacity was 1,861,744 cu. ft. The largest one was in the county of Argyll, its length being 60 ft., breadth 60, depth 16. The smallest was 6 ft. long, 4 wide, and 5 deep. See Thorold Rogers's *E. in America* (1883).

ENTABLATURE, that part of a design in classic architecture which surmounts the columns (q.v.), and rests upon the capitals. It is usually about two diameters of the column in height, and is divided in every style of classical architecture into three parts—architrave, frieze, and cornice. These parts vary in their relative proportions in different styles. In Doric architecture, for example, if the E. be divided into eight equal parts, two of these form the height of the architrave, three that of the frieze, and three

that of the cornice. In the other styles, the relative proportions are as three, three, and four.

The term E. was not used till the 17th c., the members composing it being previously simply designated the cornice, frieze, and architrave.

1. *The architrave* is the horizontal portion which rests immediately upon the abacus of the column. It is usually ornamented with horizontal moldings, with flat spaces or *faciæ* between. The upper molding always projects further than the others, so as to throw off the rain. This molding varies in different styles. In Doric, it is a plain square projection, with small pendants or *guttae* under the triglyphs. In the other styles, it is generally an ogee or talon molding. These moldings are frequently enriched with leaf ornaments, and in very florid designs the *faciæ* are also enriched.

2. *The frieze* is the middle portion of the E., between the top of the architrave and the bed of the cornice. In the Doric style, it is ornamented with triglyphs or slight projections, divided by angular grooves into three parts. The spaces between the triglyphs (called metopes) are square, and are either plain or enriched, either with figure-sculpture, as in the Parthenon, or with bulls' heads, pateræ, or other ornaments. In the other styles, the frieze is never cut into portions, but is either left quite plain or ornamented with figure-sculpture or scroll-work. The former is most usual in Greek art, the latter in Roman. In late Roman works, the frieze is sometimes *swelled* or made to project with a curve.

3. *The Cornice* forms the upper portion of the entablature. It is divided into several parts. The lower molding or moldings resting on the frieze are called the bed-moldings—the upper projecting part is called the corona (q.v.), and between the two there are frequently introduced modillions and dentil bands. The bed-molding is generally of an oval or echinus form, and is frequently enriched with the egg and tongue or leaf ornaments. The upper molding of the corona is generally of a *cymarecta* form (see COLUMN, fig. 1), and is often ornamented with lions' heads. These represent the openings through which the rain was at first led off from the roof-gutters, which were cut in the top of this molding, and were retained as ornaments after their original use was discontinued. The corona projects well over the frieze and architrave, and protects them from rain, while at the same time, by its broad shadow, it gives repose and variety of effect to the building. The *soffit*, or under side of the corona, is frequently paneled and ornamented with pateræ.

Origin.—The component parts of the E. are said, with some appearance of truth, to owe their origin to the forms of the construction of the oldest temples. These were of wood, and were put together in the manner most natural for that material. The square beams laid across from post to post are represented by the architrave; the triglyphs of the frieze are copied from the ends of the cross-beams; the cornice is taken from the boarding which covered the rafters and ties of the roof—projected so as to throw off the rain; and the dentils and modillions show the ends of the rafters left uncovered.

Whatever the origin of the E. may have been, it is a remarkable fact, as connected with Greek and Roman art, how persistent the E. was as a feature in the decoration of these classic styles. So long as buildings consisted of one story in height, this was quite natural; but after this simple system was abandoned, and when, as in Roman architecture, series of columns and entablatures were piled one above the other—not used constructionally, but simply applied to the face of the building—the cornice, frieze, and architrave still retained their places and proportions. In the revived Roman art of the 16th c., the E. was used in a manner still further removed from its original purpose. The strict proportions of the various parts were entirely lost sight of. The frieze was increased in height, so as to admit of small windows to light the entresol (q.v.) or mezzanine, and in the French and English forms of the renaissance, the various members become still more attenuated and altered from the original design (see RENAISSANCE). But in no modification of classic architecture, however debased, is the E. wanting. The architrave, frieze, and cornice are essential portions of every classic design.

ENTADA, a genus of climbing shrubs of the natural order *leguminosæ*, sub-order *mimosæ*, having pinnate or bipinnate leaves, and remarkable for their great pods, in which the seeds lie amidst a glutinous or gelatinous substance. The seeds of *E. purshiana*, an East Indian species, are saponaceous, and are used for washing the hair. The plant attains a great size; its pods are sometimes fully 5 ft. long, and 6 in. broad; the seeds are beautiful brown beans, so large that in Ceylon they are often hollowed out and used as tinder-boxes.

ENTAIL, or, as it is frequently called in Scotland, *tailzie*, from Fr. *tailler*, to cut, properly signifies any destination by which the legal course of succession is cut off, one or more of the heirs-at-law being excluded or postponed, and the settlement of land made upon a particular heir or series of heirs. The desire to preserve in our own family land which we have either inherited or acquired, appears to be inherent in the human mind. The first distinct trace of the existence of entails, is to be found in the Roman law. The Greeks, indeed, permitted persons to name successors to their estates, and to appoint a substitute who should take the estate on the failure of him first named. The substitute, as appointed, was permitted to succeed on the death of the institute (as he was called) without leaving issue or without alienating the estate. But this limited

right fell far short of the power of entailing which has since prevailed in various countries. At Rome, under the later emperors, the practice of settling land upon a series of heirs, by means of *fideicommissa* (q.v.), grew up, and was sanctioned by the state. These deeds, which were originally simply a trust reposed in the honor of a friend, to whom the property was conveyed, to carry out the will of the grantor, by degrees received the sanction of the law. In their early form they contained merely a substitution of heirs. Thus, "*Rogo ne testamentum faciat, donec liberos susceperit.*" "*Rogo ut testamento suo Scium heredem faciat.*" "*Rogo heredem, ne hereditatem alienet, sed relinquat familie.*"—Heineccius, s. 658. But by the later law, a much fuller form of settlement was admitted, whereby the estate was protected from every sort of alienation. "*Volo meas aedes non vendi ab heredibus meis, neque fenerari super eas: sed manere eas firmas, simplices, filiis meis et nepotibus in universum tempus. Si aliquis autem eorum voluerit vendere partem suam, vel fenerari super eam, potestatem habeat vendere coheredi suo et fenerari ab eo: si autem aliquis præter hæc fecerit, erit quod obligatur, inutile atque irritum.*"—Dig. xxxi. 88, s. 15. Here we have an example of the principal clauses of a strict E. as subsequently more fully carried out in Scotland. It is impossible to doubt that this Roman form must have been adopted by the Scottish lawyers in framing their deeds of entail. The limitation to a particular line of descent, the prohibition to alienate or burden with debt, and the still more peculiar feature of the declaration of forfeiture in case of non-compliance, are to be found in both forms. There are, however, two points in which the Roman law differed from that which prevailed for many years in Scotland—viz., that the former did not recognize the right of primogeniture, and that the limitation of the deed was restricted to four generations. For the right of primogeniture, as recognized in deeds of E., we are indebted to the feudal law. That system, which has united with the civil law to form a basis for the codes of modern Europe, did not, in its original form, recognize the right of a holder of land to alienate his feudal benefice. But the right of the eldest son to represent his father, both in the duties and privileges of the fief, if not an original principle of the system, was universally recognized in the days of its greatest power. We shall presently see how this principle was embodied in a Scottish deed of entail. We come now to consider entails as they have existed in modern nations.

In *England*, the Saxons, it is said, prohibited the alienation of lands by those who had succeeded to them under condition that they should not alienate.—Wilkins's *Leges Saxonice*, p. 43 (note). Among the Saxons, the law of primogeniture was not recognized. But on the establishment of the feudal laws in England, a practice began to prevail whereby an estate was settled upon a particular series of heirs, as "to a man and the heirs of his body." This is the first germ of an entail in England. It was called a fee-simple conditional, because the judges refused to recognize an absolute limitation of the estate to a particular line of heirs, but held the destination to be conditional on the birth of an heir, and that that condition having been purified, the donee was free to alienate the estate. The common law thus refusing to recognize entails, a statute was passed which had the effect of introducing that practice into England. This was the famous statute *De Donis* (q.v.), whereby it was declared that the estate should be held *secundum formam doni*. In order to the creation of an entail under this statute, it was not enough that the estate was limited to "a man and his heirs," as those words were held to constitute an estate in fee; it was necessary that the estate should be given to "a man and the heirs of his body," or "to a man and the heirs of his body by his wife Joan." The former was called a general, the latter a special entail. Another form whereby lands might be entailed under the statute *De Donis*, was by settlement in Frank-marriage (q.v.). For nearly 200 years after the passing of this act, lands settled in the form which it prescribed continued to be held under the fetters of a strict entail. But the tendency of the law, which in Scotland, as we shall presently see, was to strengthen the power of entails, was, in England, in the opposite direction. For a long time, tenants in tail, taking advantage of legal technicalities, were able practically to defeat the limitation in tail by means of a discontinuance. But it was not till the time of Edward IV. that an effectual means of evading the provisions of the act was brought into use; this was achieved by means of a process called a common recovery. See *FINE OR LANDS*. By this process, a tenant in tail could bar the E., and convert the estate into a fee-simple. Another mode of barring an E. was by means of a fine. It had been declared by the statute *De Donis*, that levying a fine of lands should be no bar to the E.; but by 32 Hen. VIII. c. 36, it was enacted that a fine of lands, when duly levied, should be a complete bar to the tenant in tail, and those claiming under him. It is to be observed that the operation of a fine was confined to those claiming under the tenant in tail; those who had rights of reversion or remainder under the grantor of the E. were not excluded by this species of assurance; so that by means of a recovery only could an estate tail be converted into a fee-simple. From the introduction of common recoveries till the passing of the fines and recoveries act (3 and 4 Will. IV. c. 74), a period of more than 300 years, it was impossible that an estate could be held under the fetters of an E., if the tenant in tail and the next heir chose to combine to defeat the entail. By the fines and recoveries act, the technicalities formerly necessary in order to bar an E. were removed, and tenant in tail may now, by a simple conveyance, alienate his estate at pleasure. An estate tail is a freehold of a limited

description. Tenant in tail may commit waste (q.v.). Formerly, an estate tail was not liable to the debts of the tenant, but by 1 and 2 Vict. c. 110, this restriction has been removed. Copyhold lands have been held not to fall under the operation of the statute *De Donis*. A limitation, therefore, which in a freehold creates an estate tail, in copyhold lands creates a fee-simple conditional, according to the old common law, except where the custom of the manor is to the contrary.

In Scotland, as in England, entails appear first to have taken their rise from the feudal usages. It has been observed by lord Kames, that while the feudal system was in its vigor, every estate was in fact entailed, because no proprietor had any power to alter the order of the succession. But when the stricter feudal principles gave way, and the power of alienating land began to be recognized, the holders of estates sought to secure, by deed, in their own families the lands which they possessed. The form first adopted for this purpose was the simple destination, whereby the estate was simply limited to a particular series of heirs, without prohibition to alienate, or declaration of forfeiture for contravention of the will of the grantor. In this form, the deed must have resembled the early English entails. The feudal law of primogeniture having been received as a principle of common law, the estate would naturally descend from father to son in the line indicated by the deed. But, as it was held that those succeeding under this deed were not restrained from alienating, the practice of adding prohibitory clauses was introduced. Entails in this form were held to bind the heir from granting gratuitous alienations; but he was not restrained from selling the estate, or burdening it with debt. Early in the 17th c., a further addition was made to the form of the deed by the introduction of irritant and resolute clauses, i.e., clauses declaring the act of alienation to be null, and to infer the forfeiture of the estate. The form thus adopted, which resembles closely the form of the Roman deed already noticed, was fortified by a decision of the court of session in the *Stormont E.*, M. 13,994, holding that an estate so protected could not be attached by creditors. This decision created much difference of opinion amongst lawyers as to the power of the grantor thus to protect an estate from the onerous act of the heir, in consequence of which the famous Scotch E. act, 1685, c. 22, was passed, by which it was enacted that an estate conveyed by a deed fortified by prohibitory, irritant, and resolute clauses, and recorded in a particular register, should be effectually secured in the line of destination. This act has always been most strictly viewed by Scottish lawyers; and entails which have been found deficient in any of the prescribed requisites, have been regarded by the courts as utterly ineffectual. The first lord Meadowbank, in a judgment which has always been regarded as a leading authority, laid it down that entails "are the mere creatures of statute," and that where the interests of third parties are concerned, every part of an E. is liable to the strictest interpretation (*Hamilton v. Macdowall*, 3d Mar., 1815). The operation of the old E. act was found, notwithstanding, to be of the most oppressive character. Statutes were in consequence passed from time to time, empowering heirs of E. to exercise larger powers of ownership than could be granted under the act 1685, and to make provisions for their families. At length, by 11 and 12 Vict. c. 36, and 38 and 39 Vict. c. 61, the power of fettering lands by a strict E. has been finally destroyed. By this act, heirs under an existing E. may disentail, with the consent of certain heirs next in succession; and in all entails made after 1st Aug., 1848, and also in old entails where the heir in possession was born since 1st Aug., 1848, the heir of E. in possession may, by means of a simple deed of disentail, free his estate from the restrictions of the entail.

In America, before the civil war, the English law as to estates tail prevailed. But in the United States the law of entails has been gradually abandoned by the several states; and property can now be fettered, to a limited extent only, by means of executory devices (q.v.). In France, the power of creating entails has varied much at different periods, from the right to make a perpetual E., which appears to have been the original principle, to a limitation to four, and at one time to two degrees. But by the code Napoleon, ss. 896-897, entails are now absolutely prohibited. In Spain, also, entails, which were permitted under certain restrictions, have been entirely abolished by a law of the cortes in 1820. Thus it will be seen that the right of securing land in a particular family, which commends itself to the natural feelings, has been found so oppressive in operation, and so injurious to the public interest, that after an existence of more than 600 years it has been practically discarded almost simultaneously by the general consent of modern nations.

Gardiner's Island (q.v.), the oldest of the manorial grants in the colony of New York, and confirmed as a manor and lordship in 1668, is believed to be the only property in the United States still (1891) held in entail by direct descendants of the grantee. Down to 1829 it descended in unbroken succession from father to eldest son, and then passed, through lack of issue, to a younger branch of the family.

ENTAIL, or ENTAYLE (Fr. *tailler*, to cut), often used by old English authors for any architectural ornament which is sculptured or cut in stone. Chaucer speaks of

"An image of an other entaille;"

and other examples are given by Parker (*Glossary of Architecture*).

ENTASIS (Gr.), the swelling outline given to the shaft of a column (q.v.).

ENTELECHY (Gk. *perfection*), the absoluteness, actuality, actual being of a thing, opposed to mere potentiality or capability. The term was employed by Aristotle in his psychology. In Aristotle's view, the world is a perpetual process of development, a ceaseless transformation of that which merely has the *power of being* into that which actually exists. Existence therefore shows two inseparable and correlative aspects of its operations—a state of *potentiality* or capability on the one hand and a state of *realization* on the other, this realization being itself in turn only a stage of potentiality for the development of some other aspect of reality. Without soul, the body is a mere potential existence, a mere possible substratum for development in the future: it is nothing actual or real. Just as the seed reaches its true meaning in the tree, so the soul constitutes the real significance of the body. Soul is thus not only the realization, the true meaning of body, but also in a sense its end, for when an organism has advanced so far as to possess a soul, it has reached, as it were, the last stage in development. Entelechy in short is the realization which contains the end of a process, the complete expression of some function, the last stage in the process from potentiality to actuality. Iron, for example, exists potentially in its ore, which must be worked to be made iron. When this is done, the iron exists in entelechy. Aristotle makes a distinction between *first* and *second* entelechy, calling the soul the first entelechy of the body. Any development may be either implicit or explicit. For example, the knowledge through which man gains the perfect realization of his faculties may be either knowledge possessed but dormant in the mind, or it may proceed to something further and be this same knowledge consciously used and applied. Now it is in the first of these two senses that soul is the entelechy of the body. It is the first or earliest, the relatively dormant or implicit realization in which our bodily processes attain their real truth. To sum up, by calling the soul the first entelechy of the body, Aristotle means that it is the perfect development which having reached the stage of realization is nevertheless capable of continued action. "First entelechy is being in working order, second entelechy is being in action." This article is based chiefly on Edwin Wallace's *Aristotle's Psychology*, page XLIII. See also Trendelenburg ad Arist. de Anima, pp. 295 seq.; and Brandis, *Aristoteles und seine Akademischen Zeitgenossen*.

ENTELLUS MONKEY, or **HONUMAN** (*semnopithecus entellus*), an East Indian species of monkey, with yellowish fur, face of violet tinge, surrounded with projecting hairs, long limbs, and very long, muscular and powerful—though not prehensile—tail. It is held in superstitious reverence by the Hindus, and is often to be seen exhibiting much impudent familiarity in the precincts of temples; indeed, temples are often specially dedicated to it; hospitals are erected for its reception when sick or wounded. Hindu laws affix a far more severe punishment to the slaughter of one of these sacred monkeys than of a man; the peasant esteems it an honor when his garden is plundered or his house robbed by troops of them, and would consider it an act of the greatest sacrilege to drive them away. They take their places with perfect confidence on the roofs of houses, and gaze at the passing crowd. This is one of the very few species of monkeys found in the northern provinces of India, and in summer ascends the Himalaya to the pine-forests, and almost to the snow-line; it has even succeeded in crossing the mountains, and occurs in Bhotan.

ENTERIC FEVER is another name for enteritis, which will be found described below.

ENTENTE CORDIALE (Fr.). This expression denotes literally a friendly or cordial understanding; but it is used specifically in politics to denote the friendly relations existing between different countries and statesmen. It may be said, for example, that an *entente cordiale* now exists between England and the United States.

ENTERITIS (Gr. *enteron*, the intestines), inflammation of the bowels, and especially of their muscular and serous coat, leading to constipation (q.v.) and pain, with colic (q.v.), and sometimes ileus (q.v.). E. is distinguished from these last affections, indeed, only by the presence of inflammatory symptoms—i.e., pain, tenderness, fever, etc., from a very early stage of the disease, and in so decided a form as to require special attention. If E. does not depend upon mechanical obstruction, it may be combated by hot fomentations, with moderate leeching and counter-irritation, and the internal administration of opium. Injections of warm water, or of asafetida and turpentine (see **CLYSTER**), should be at the same time given to clear the lower bowel; and all purgatives, except in some cases castor oil, should be avoided. The disease is, however, one of great danger, and should never be incautiously treated with domestic remedies. It is closely allied to peritonitis (q.v.), and often depends upon internal mechanical causes, or on external injury.

In the Lower Animals.—Inflammation of the bowels, among the heavier breeds of horses, generally results from some error of diet, such as a long fast, followed by a large, hastily-devoured meal, indigestible or easily fermentable food, or large draughts of water at improper times. When thus produced, it is frequently preceded by stomach staggers or colic, affects chiefly the mucous coat of the large intestines, and often runs its course in from eight to twelve hours. With increasing fever and restlessness, the pulse soon rises to 70 or upwards, and, unlike what obtains in colic, continues throughout considerably above the natural standard of 40 beats per minute. The pain is great, but the animal, instead of recklessly throwing himself about, as in colic, gets up and lies down

cautiously. Respiration is quickened, the bowels torpid. Cold sweats, stupor, and occasionally delirium, precede death. When connected with, or occurring as a sequel to influenza, laminitis, and other complaints, the small intestines are as much affected as the large, and the peritoneal as well as the mucous coat of the bowels. This form is more common in the lighter breeds. When the patient is seen early, whilst the pulse is still clear and distinct, and not above 60, and the legs and ears warm, blood-letting is useful, as it relieves the overloaded vessels, and prevents that exudation of blood which speedily becomes poured out in the interior of the bowels. This disease should be treated as follows: In a pint of oil, or an infusion of two drams of aloes in hot water, give a scruple of calomel and an ounce of laudanum, and repeat the calomel and laudanum every hour in gruel until the bowels are opened, or five or six doses are given. Encourage the action of the bowels by using every half-hour soap and water clysters, to which add laudanum so long as pain and straining continue. If the animal is nauseated and stupid, with a cold skin, weak quick pulse, bleeding and reducing remedies are very injurious; and the only hope lies in following up one dose of the calomel and aloes with small doses of laudanum and sweet spirit of niter, or other stimulants, repeated every forty minutes. In all stages, woolen cloths wrung out of hot water and applied to the belly encourage the action of the bowels, and relieve the pain.

E. in cattle is mostly produced by coarse wet pasture, acrid or poisonous plants, bad water, and overdriving. The symptoms are fever and thirst, a quick but rather weak pulse, restless twitching up of the hind limbs, tenderness of the belly, and torpidity of the bowels. Calves generally die in three or four days, other cattle in a week or nine days. Bleed early, open the bowels with a pint of oil and a dram of calomel, which may be repeated in eight or ten hours, if no effect is produced. Give every hour fifteen drops of Fleming's tincture of aconite in water, until six or seven doses are given. Allow only sloppy and laxative food, such as treacle, gruel, or a thin bran mash; employ clysters and hot cloths to the belly, and use two ounce doses of laudanum if the pain is great. E. in sheep mostly occurs in cold exposed localities, and where flocks are subjected to great privations or improper feeding.

ENTEROPNEUSTA (Gr. "gut-breathers") a class of worm-like animals having paired respiratory pouches opening from the front part of the alimentary canal. Its members, which in their characters resemble vertebrates, include *balanoglossus* and *cephalodiscus*.

ENTERPRISE, a town and winter resort in Volusia co., Fla.; on lake Monroe, the Jacksonville, Tampa, and Keywest railroad, and the St. John's river line of steamers; 198 miles s. of Jacksonville. It is on the opposite side of the lake from Sanford, has several hotels and, near by, a noted sulphur spring, and is much frequented by rheumatic persons.

ENTHYME (Gk., from the verb *enthumeisthai*, "to revolve in the mind"), a term used by Aristotle, to denote the rhetorical syllogism, viz., a syllogism "from *probabilities* and *signs*." The *probability* is a general proposition, stating that which usually happens, as, "wise men are just." By *sign* he designated particular propositions, as, "Socrates is just," or according to others, "by signs he designates facts or marks, such as attend on other facts or conceptions, so that from the presence of the sign we suspect or know that the thing signified is present." The sign may be either fallible or infallible. If we say, "Wise men are just, for Socrates was wise and just," we have an enthymeme from a fallible sign, the implied syllogism being "Socrates was wise; Socrates was just (sign); therefore, all wise men are just." If we say, "Here is a sign that he is ill—he is feverish," our enthymeme is using an infallible sign, the syllogism being, "all who are feverish are ill; he is feverish (sign); therefore, he is ill." The premises of such syllogisms seldom belong to the class of necessary facts. "The propositions from which enthymemes are taken," says Aristotle, "will sometimes be necessarily true, but more often only contingently true." Aristotle did not regard the suppression of one premise in the statement as essential to the enthymeme. This is shown by his remark that the enthymeme may often be more concisely stated than the full or normal syllogism. There is no reason why the rhetorical reasoner should not state both his premises, if he finds it convenient or effective to do so. Since, however, one of the premises is often left to be supplied, some of the later writers on rhetoric came to treat this as part of the essence of the enthymeme. Thus, Quintilian says of the enthymeme, "Some call it a rhetorical syllogism, others an imperfect syllogism." In accordance with this idea, Webster defines enthymeme thus: "An argument consisting of only two propositions, an antecedent and a consequent deduced from it; as, We are dependent; therefore, we should be humble. Here, the major proposition is suppressed. The full syllogism would be: Dependent creatures should be humble; we are dependent creatures, therefore we should be humble."

ENTOMOLOGY (Gr. *entomon*, an insect, *logos*, a discourse), the science which has insects (q.v.) for its subject. The mere collector of insects may be one of the humblest laborers in the great field of natural history, but his labors contribute materials for the more philosophic naturalist who studies the structures of these creatures, and compares them with one another according to the unity and the variety of design which they exhibit. And when we begin to take into account the vast number of different species of insects, their great diversities of structure and of habits, their great complexity of organization,

the wonderful transformations which many of them undergo at different stages of their existence, and the equally wonderful but extremely various instincts which many of them display, we find E. to be a science worthy to engage the noblest mind. But besides all these things, we must remember that insects serve most important purposes in the general economy of nature; and that some of them are directly useful to man, some directly injurious, at least when their numbers are at any time excessively multiplied.

E., along with the other branches of natural history, was cultivated by Aristotle and other Greeks. Aristotle is the most ancient author of whose works anything relating to this science now remains. Pliny has little on this subject but what is copied from Aristotle; and it can scarcely be said to have been again studied as a science till the 16th c., when attention began once more to be directed to it, although it was not till the 17th c. that much progress was made, or that any important works on E. appeared. Insects then began to be described, not only those of Europe, but also some of the curious and splendid insects of tropical countries; bees and other insects of particular interest received attention; the metamorphoses of insects began to be studied, and their anatomy to be investigated. The names of Goedart, Malpighi, Swammerdam, Leuewenhoek, and Ray deserve to be particularly mentioned; but the infant state of the science may be illustrated by the fact, that about the end of the 17th c., Ray estimated the whole number of insects in the world at 10,000 species, a number smaller than is now known to exist in Britain alone. In the 18th c., the name of Linnæus occupies as high a place in the history of E. as in that of kindred branches of science. The progress of the science was much promoted by his arrangement and exhibition of the discoveries of previous and contemporary naturalists; and by his system of classification, founded on characters taken from the wings, or their absence, a system professedly artificial, yet so harmonizing with the most natural distribution into groups, that some of its orders were indicated by Aristotle, and that it has retained and seems likely to retain its place, modified, indeed, but not essentially changed. De Geer and Fabricius are perhaps, after Linnæus, the most worthy to be named of the great entomologists of the 18th century. At the close of the 18th and beginning of the 19th c., the name of Latreille is pre-eminently conspicuous; and in the year 1815, a new impulse began to be given to the study of E. in Britain by the publication of the admirable *Introduction to Entomology* of Messrs. Kirby and Spence, a work combining in a remarkable degree the merits of being at once popular and scientific. Since the beginning of the 19th c., the number of insects known and described has prodigiously increased; many entomologists have with great advantage devoted themselves particularly to the study of particular orders of insects; and many valuable monographs have appeared. Entomological literature has now become very extensive. The progress of the science has owed not a little to entomological societies, of which the entomological society of London may be particularly mentioned. We cannot attempt to enumerate the distinguished entomologists of the 19th c., but perhaps the names of Leach, Macleay, Curtis, Stephens, Westwood, Smith, Walker, Stainton, Swainson, and Newman, deserve particular notice among those of Britain; Meigen, Jurine, Gyllenhal, Gravenhorst, Hubner, Dufour, Boisduval, Erichsen, and Lacordaire among those of the continent of Europe; and Say among those of America. It is to be regretted that we have not yet any complete work on the insects of Britain. The *Insecta Britannica*, of which some volumes by different authors have been published under the auspices of the entomological society, is intended to supply the want. See also American works on ants, by McCook; Packard, *Guide to the Study of Insects*; Our Common Insects; Harris, *Insects Injurious to Vegetation*; Scudder, *The Butterflies of the Eastern United States and Canada*.

ENTOMOSTRACA (Gr. insect-shells), a term introduced by Müller, and adopted by Latreille, Cuvier, and other naturalists, to designate the second of their two great divisions of crustaceans (q.v.). The number of species of E. is very great. They are all of small size, except the king-crabs (*limulus*), which in many respects differ from all the rest, and have recently been formed by some naturalists into a sub-class of crustaceans by themselves. Many of them are minute, and exist in great numbers both in fresh and salt water, particularly in stagnant or nearly stagnant fresh water, affording to many kinds of fishes their principal food. They differ very much in general form; the number of organs of locomotion is also very various—in some very few, in some more than 100—usually adapted for swimming only, and attached to the abdominal as well as to the thoracic segments; but there never is a fin-like expansion of the tail, as in some of the malacostracous crustaceans. The antennæ of some are, however, used as organs of locomotion. Some of the E. have mouths fitted for mastication, and some for suction. Not a few are parasitic. The heart has the form of a long vessel. One or two nervous knots or globules supply the place of a brain. The organs of respiration are in certain species attached to some of the organs of locomotion, in the form of hairs, often grouped into beards, combs, or tufts, or blade-like expansions of the anterior legs are subservient to the purpose of respiration; in others, no special organs of respiration are known to exist. The eyes are sometimes confluent, so as to form a single mass—one eye—in the front of the head. The name E. has been given to these creatures in consequence of most of the species having shells of one or two pieces, rather horny than calcareous, and of very slender consistence, generally almost membranous and transparent. In

very many, the shell consists of two valves, capable of being completely closed, but which, at the pleasure of the little animal, can also be opened so as to permit the antennæ and feet to be stretched out.

The study of the smaller crustaceans has recently been prosecuted with great assiduity and success, by Milne-Edwards and others; and in consequence of the great differences existing among them, new classifications have been proposed, and the name *E.* has by some been restricted to those which have a mouth formed for mastication, but no special organs of respiration, forming a section which is subdivided into two orders, *ostrapoda* and *copepoda*, the former having a bivalve shell or shield, the latter destitute of it.—But the name *E.* is still commonly employed in its former wider sense.

ENTOMOSTRACA, FOSSIL. *E.* attained their maximum size in the palæozoic waters, which they tenanted in vast shoals. The Silurian trilobite (q.v.) was a phyllopod, and the pteregotus of the old red sandstone was nearly allied to the modern limulus. Small bivalvular species are found in all strata, sometimes, as at Burdie-house, near Edinburgh, forming layers of considerable thickness, at others scattered in enormous numbers in the dried sediments of lakes, as in the fresh-water clays of the Wealden, or forming in some places a large proportion of chalk, with the multitudes of their thin calcareous coverings.

ENTOPHYTES (*Entophyta*; Gr. *enton*, within, and *phyton*, a plant), a term usually employed to denote those parasitic plants which grow on living animals. It is seldom extended to vegetable parasites which grow on living vegetables, whether on external or internal parts, nor is it restricted to those which are found in the internal cavities, or within the substance of animal bodies, but includes all which have their seat on living animal tissues. It does not, like the analogous term *entozoa*, denote any particular class of organized beings; some of the *E.* are *algæ*, and some *fungi*, but to these two orders they are limited, and all of them belong to the lower sections of these orders; some of them to those lowest sections in which the distinguishing characters of the two orders cannot easily be traced, so that they are referred to the one or the other on very slender grounds; those in which a coloring matter is present being reckoned *algæ*, although it can be observed only in masses of aggregated cells, and not in the cells when viewed separately, and those which even in the mass appear entirely colorless, being considered *fungi*. Many of the *algæ* and *fungi* parasitic on plants are nearly allied to those which occur on animals; thus, ergot and the kind of mildew which has proved so destructive to vines, are referred to the same genus (*oidium*) to which is also referred the fungus found in the diseased mucous membrane in cases of *aphthæ* or *thrush*: and another genus (*botrytis*, q.v.) contains the fungus called muscardine, or silkworm rot, so destructive to silkworms, together with the fungus which accompanies or causes the potato disease, and many other species which infest plants. Common mold is even supposed to occur on animal tissues tending to decay, during life, as well as on dead animal and vegetable substances.

Vegetable parasites occur both in man and in the lower animals; not a few of them are peculiar to fishes, and more are peculiar to insects than to any other class of animals. The fungi which grow on the bodies of insects sometimes attain an extraordinary development: *sphaeria Sinensis*, which grows on a Chinese caterpillar, and to which medicinal virtues, probably imaginary, are ascribed in China, attains a length greater than that of the caterpillar itself. A similar species (*S. Robertsi*) is found on the caterpillar of a New Zealand moth.

The situations in which *E.* occur are very various. Some, like the thrush fungus already noticed, appear in diseased conditions of the mucous membrane; some find their place in the lungs, the ear, or other organs; some on the skin, in the hair follicles, and *in* as well as *on* the hair itself. The “fur” which appears on the tongue when the stomach is disordered, abounds in the extremely slender unbranching threads of the *algæ* called *leptothrix buccalis*, which also vegetates luxuriantly in cavities and corners of the teeth not sufficiently visited by the tooth-brush. The lungs of birds, the gills of fishes, the intestines of insects, the wing-covers of beetles, the eggs of mollusks, all have their peculiar vegetable parasites by which they are sometimes infested.

It is often by no means easy to say whether the presence of *E.* is to be regarded as the consequence or as the cause of disease; sometimes it may be both. Sometimes it appears to be certainly a consequence, as when the *sarcina* (or *merismopæ*) *diacentriculi* occurs in the contents of the stomach and bowels; sometimes, as in the diseases called *favus*, *porrigo*, *tinea*, *herpes tonsurans*, *plica polonica*, *mentagra*, *pityriasis versicolor*, etc., it seems entitled to be regarded as the cause of the diseased state, and the cure of the disease seems to be accomplished by killing the parasite, often a thing of no little difficulty.

Whence the germs of *E.* are derived is often a question to which it would not be easy to find an answer. Their spores are extremely minute; but there are no plants which produce seeds or spores more abundantly than some of them do; the growth of the plants themselves is very rapid, and reproduction is “very intense and rapid.”

It has sometimes been imagined that epidemic diseases may be caused by spores of *E.* conveyed through the air; no evidence has, however, been produced to render this

opinion probable. An attempt was made to establish the existence of cholera fungi or algæ, but it completely failed.

ENTOZO'A. This term is applied to all the animal forms which live either in the natural cavities (as, for example, the intestinal canal), or in the solid tissues (as, for example, the liver) of other animals. The number of these parasites is so great (there being at least 20 distinct species of worms found in man, 14 in the dog, 15 in the horse, 11 in the common fowl, etc.), and their occurrence so frequent, especially in some of the lower animals, that we must regard their presence, at all events in many species, rather as the normal condition, than as a morbid state due to accidental causes.

It is worthy of notice, that many of the animals included amongst the E. only enjoy a parasitic existence during a part of their total life, which often, as in the well-known case of perfect insects, presents very varied and distinct phases. Thus, for example, the larvæ of the gadfly (*œstrus equi*) undergo their entire development in the stomach of the horse, attaching themselves by minute hooks to the gastric mucous membrane; they then detach themselves, pass along the intestines, and in due time are discharged, and undergo their further changes externally; and many similar instances might be quoted. For this reason, and additionally because parasites are now known to belong to various classes of animals, we no longer attempt, like Linnæus and Cuvier, to form a special group of E.; and a reference to the *vermes intestinales* in the *systema naturæ*, or to the *entozoaires* in the *règne animal*, at once shows that these illustrious naturalists grouped together animals with few or no true natural affinities.

Although most E. belong to the class of *vermes*, or *worms*, this, as has been already observed, is by no means exclusively the case. Thus, even fishes may lead a parasitic existence; a fish of the genus *flæasfer* being frequently found in the respiratory cavity of the *holothuria tubulosa*, or *sea-cucumber*, and small fishes having been frequently observed in the cavity of the *asteria discoides*. Amongst the crustaceans, instances of parasitism are by no means rare; different species of *lernæa* being abundant in the branchial (or gill) cavity, and on the surface of numerous fishes, while the *linguacula* infest mammals, reptiles, and fishes, being found in the olfactory sinuses, the larynx, the lungs, the peritoneal cavity, etc. The instances in which mollusks are found to live parasitically are few; certain gasteropods, however, inhabit the bodies of echinoderms, holothurians, and comatulas; and amongst the lamellibranchiates, species of *modiolaria* and *mytilus* live in the bodies of ascidians. There are several cases of polyps which have been observed to adopt a parasitic existence; and finally, various protozoa are not unfrequently met with in the animal fluids; for example, certain species of *vibrio*, *cercomonas*, and *paramecium*, have been found in the intestinal evacuations in cholera and diarrhea; *monads* have been found in the urine in cholera, and certain infusoria and rhizopoda in the blood of the dog, the frog, and many other animals. See HEMATOZO'A.

The more common kinds of E. appear to have attracted the notice of the earliest physicians and naturalists whose opinions or works have reached us. Hippocrates speaks of several worms, especially the tæniæ and ascarides, infesting the human intestinal canal; and Pythagoras learned in India that the bark of the pomegranate acted almost as a specific in cases of tape-worm. Aristotle noticed both the tape-worm of the dog and of man, and the *cysticercus cellulosa* (see CESTOID WORMS) of the pig; but utterly unconscious that the cysticercus, under favorable conditions, became developed into a tape-worm (see TAPE-WORM), referred the origin of all intestinal worms to spontaneous generation—a doctrine that seems to have been generally adopted till the 17th c., when Redi published (in 1684) a work on helminthology, in which he distinctly showed that the generation of various E. followed the same laws as in higher animals, and that in many instances there were distinct males and females. The great recent discovery, that the vesicular or bladder-like parasites, such as the different species of cysticercus and cœnurus, are cestoid worms in an early stage of development, is alluded to in CESTOID WORMS, and will be more fully noticed in the article TAPE-WORM.

Another point of general interest in connection with E. is the part of the body in which they are found. While most live in the intestinal canal and other open cavities (as the larynx, bronchial tubes, etc.), others are found in the closed cavities and in the parenchymatous tissue of the liver and other solid organs. Thus (confining our remarks to the E. occurring in man), *anchylostoma duodenale*, *strongylus duodenalis*, two species of *ascaris*, *oxyuris vermicularis*, *trichocephalus dispar*, *distoma heterophyes*, at least four species of *tænia*, and *bothriocephalus latus*, have been found in different parts of the intestinal canal; while *strongylus gigas* inhabits the kidney, another species of *strongylus* the lungs, a species of *spiroptera* the bladder, two species of *filaria* and *monostoma lentis* the eye, *trichina spiralis* the voluntary muscles, two species of *echinococcus* and *cysticercus cellulosa*, various parenchymatous tissues, two species of *distoma* the gall-bladder, another species the portal vein, and the *filaria medinensis*, or *guinea worm*, the subcutaneous tissue.

Davaine, who may be regarded as one of the highest living authorities on this subject, gives the following synopsis of the E. occurring in man and the domestic animals (see his *Traité des Entozoaires*, Paris, 1860).

TYPE I. PROTOZOA, including the genera *bacterium*, *vibrio*, *monas*, *cercomonas*, *trichomonas*, *paramecium*.

TYPE II. CESTOIDEA, including the families of *teniadæ* and *bothriocephalidæ*. The *teniadæ* occur (1) in their undeveloped, cystic, or vesicular form, constituting the genera *cœnurus* and *cysticercus*; and (2) in their perfect, ribbon-like shape, constituting the genus *tenia*, of which about 20 species have been described. The *bothriocephalidæ* contain the single genus *bothriocephalus*, which embraces various species. Their early or vesicular stage has not yet been described.

TYPE III. TREMATODEA, including two well-marked secondary types: (1) The *poly-stomidæ*, which live as epizoa on the skin or gills of aquatic animals, and which do not concern us here; and (2) the *distomidæ*, including the genera *monostoma*, *distoma*, *holostoma*, *amphitoma*, with the doubtful genera of *tetastoma* and *hexathrydium*.

TYPE IV. ACANTHOCEPHALA, with the single genus *echinorhynchus*.

TYPE V. NEMATOIDEA. Passing over two cases in which these worms have been discovered, apparently in their larval or imperfectly developed state (once by Rainey in the human trachea, and once by Vulpian in the kidney of the dog), Davaine gives the following genera, *oxyuris*, *ascaris*, *spiroptera*, *trichina*, *trichosoma*, *trichocephalus*, *filaria*, *doelmeius*, *sclerostoma*, *strongylus*, *anchylostoma*, *dactylius*.

TYPE VI. ACANTHOTHECA, including the genus *pentastoma*.

Alarming as the above list may seem, comparatively few of the worms contained in it do in reality give rise to dangerous or severe symptoms. It seems to be a condition of parasitism, that the animal upon which the parasite lives must not be destroyed by it; and it has been suggested by one of our highest authorities on this subject, Van Beneden, that in many cases the parasite does not so much attack the organism in which it exists, as its superabundant products. Dujardin and other helminthologists have described cases in which worms were developed by thousands in persons apparently in good health. The symptoms occasioned by ascariides, tæniæ, etc., are described in the articles **ASCARIS**, **TAPE-WORM**, etc.

The multiplication of worms is most rapid in debilitated persons, especially children living in cold and damp situations; and impure water, unripe fruits, and raw or imperfectly cooked meat, have considerable influence on the development of these animals. For the description of the medicines used for their destruction, see the article **VERMIFUGES**; and for information regarding the structure and habits of the most important E., see the articles **ASCARIS**, **BOTHRIOCEPHALUS**, **CESTOID WORMS**, **GUINEA-WORM**, **MONOSTOMA**, **NEMATOIDEA**, **STRONGYLUS**, **TAPE-WORM**, **THREAD-WORMS**, **TREMATODA**, **TRICHINA SPIRALIS**, **TRICHOCEPHALUS**. See *illus.*, **WORMS, ETC.**, vol. XV.

ENTR'ACT, in music, is an instrumental piece, composed in the form of a little symphony or overture, to be performed between the acts of a play.

ENTRÉ DOURO E MINHO, or, as it is frequently called, **MINHO**, a province of Portugal, in the extreme n.w. of the country, is bounded on the n. by Galicia, from which it is separated by the river Minho; on the e. by Galicia and Trás-os-Montes; on the s. by the province of Beira, from which it is separated by the river Douro; and on the w. by the Atlantic ocean. It has an area of about 2,807 sq. m. and a pop. (1890) of 1,098,356. It has been called the paradise of Portugal, and indeed it may be doubted whether any territory in Europe of equal extent exhibits so much beauty. It is traversed from n.e. to s.w. by three mountain-ranges, which, however, sink down as they approach the coast, leaving a considerable tract of undulating country along the sea-margin.

ENTREMETS, **ENTRÉES**, French terms now generally used to designate certain courses of dishes served at fashionable dinners. The chief dishes are *entrées*, and the lighter dishes are *entremets*.

ENTRENCHMENT. See **FORTIFICATION**.

ENTRERÍOS (the Spanish for *between rivers*) takes its name from its occupying the space between the Parana and the Uruguay. It is one of the states of the Argentine confederation. The area is estimated at 45,000 sq. m. and the population in 1895 at 290,994 inhabitants. The country is almost entirely pastoral—its principal productions being hides, horns, tallow, and jerked beef. The soil is not well fitted for cultivation, for, besides being rather swampy throughout, it is subject, in the south, to annual floods. The capital is Concepcion del Uruguay.

ENTRESOL is a low story between two main stories of a building (generally between the ground floor and the first story), or between two portions of one story, when certain rooms are of greater height than the others upon the same floor. The rooms in the E. are called *entresols* or *mezzanines*.

ENTROP'ION, or **ENTROPION** (Gr. *en*, in, and *trepō*, I turn), inversion of the eyelashes, or even eyelid, consequent either on loss of substance, or on inflammatory swelling of the lid. If confined to one or two eyelashes, they should be plucked out by the roots, and the bulbs should be cauterized; but the radical cure of severe entropion requires a careful adaptation of the surgeon's art to the circumstances of the particular case, and should not be attempted by unskilled hands.

ENTRY, RIGHT OF. In the law of real estate the **right of entry upon lands** is legally held by any one who has the right of possession. It amounts to a peaceable assertion of his title not preceded by an action at law. This right exists where previous entry had

been made by a claimant without lawful title, as where the legal owner had been wrongfully dispossessed. Where the right of entry has been justly exercised the law will sustain him who has made the entry, but where the original entry of the opposing party was on its face lawful, the real owner of the estate must resort to an action at law, and his entry under such circumstances will not give him any better standing in court than he before held, as the supreme court of one of our states has said, "An entry at common law is nothing more than an assertion of title by going on the land. . . . Anciently an actual entry was required to be made, but now nothing of that kind is required." The word entry under the United States statutes relating to public lands denotes, not the actual going upon the land, but the filing of the claim in the records of the land office.

ENVELOPES. Until the introduction of the penny-postage system, E. for written letters were very little adopted; it was far more customary to secure, by wafer or sealing-wax, the sheet of paper on which the letter was written. When the postage was rendered uniform for all distances, and prepayment enforced, or at least recommended, it was supposed that stamped E. would be convenient coverings for letters, sealing the letter and paying the postage at one operation. Such has indeed been the case; but the envelope-manufacture has since taken a new direction, and to an extent that no one could have contemplated. Several large firms in London and elsewhere can make E. more cheaply than the government, and can vary the size, shape, color, and quantity to an indefinite degree; as a consequence, although E. bearing the government impressed stamp are still in demand, the unstamped varieties are used in very much larger quantities. They are made by two methods, involving different amounts of machine-power. The paper is first cut into quadrangular pieces rather longer than wide, by a cutting blade brought to bear upon a pile of sheets at once; and then cutting-dies reduce these pieces to the proper shape, generally lozenge or diamond form, but sometimes with curvilinear edges. For some kinds, it is found to economize both time and paper to stamp the pieces out at once from the rough sheets. The subsequent folding and gumming are performed generally by hand, sometimes by machine. In the hand-method, women and girls fold with almost incredible quickness, having very simple guide-pieces to aid them in giving the proper oblong quadrangular shape to the fold. The gum is applied with a small brush, either along the overlapping edges, or in spots here and there, according to the quality of the envelope.

The envelope-machines, however, such as those of Messrs. De la Rue, are beautiful examples of automatic mechanism. In the kind invented and used by this celebrated firm, a cutting-machine severs the blanks or papers; and dies are employed to stamp the device on the spot where the seal would otherwise lie. The blanks are then fed into the folding-machine, where they pass through a curious series of processes. Each blank is carried down into a box, where a plunger makes four creases in it; two short levers fold down two of the flaps thus made; a gumming apparatus comes up, and applies a line of wet gum to each flap-edge; two small levers then fold down the other two flaps (but only fastening one of them); and finally, the envelope is shifted aside to a pile, and makes way for another. All these processes are gone through in *one second*, enabling the machine to make 60 E. per minute. Where 12 of these machines are working at once, it will be seen that a million E. are put out of hand in a very short time.

ENVOY, a diplomatic minister of the second order, i. e., inferior in rank to an ambassador. Envoys ordinary and extraordinary, ministers plenipotentiary, the inter-nuncios of the pope, and all other inferior diplomatic ministers, differ from ambassadors in this, that although they receive their credentials, like ambassadors, immediately from their sovereign, they represent not his personal dignity, but only his affairs. They stand to him just as an ordinary agent does to his principal, and their acts or promises are his in a business, though not in a personal sense. It is said that this class of diplomatists was first introduced by Louis XI. of France, towards the end of the 15th century. The E. is superior in rank to the chargé d'affaires, whose credentials proceed from the ministers of the state from which he is sent, and are addressed to the minister of the state to which he is sent; or are a mere delegation from an ambassador or E. to conduct the affairs of the mission in his absence. Consuls (q.v.) are not generally reckoned among diplomatic ministers, though, where they have diplomatic duties to perform independently of an ambassador or E., they are accredited, and treated as ministers. According to the division of diplomatic agents into four classes, which was made by the great powers at the congress of Vienna in 1815—viz.: 1. Ambassadors, legates, and nuncios; 2. Envoys, ministers, and other agents accredited to sovereigns; and 3. Chargés d'affaires, accredited by and to the departments of foreign affairs—an E. would be of the second, and a chargé d'affaires of the third rank. But the practice of this country has interjected between the ambassador and the E. a second class, called envoys extraordinary and ministers plenipotentiary, which, of course, throws the ordinary E. into the third, and the chargé d'affaires into the fourth class. See **AMBASSADOR**; **CHARGÉS D'AFFAIRES**; **CONSUL**; **DIPLOMACY**; **EMBASSY**; **MINISTER**.

ENZIO, or **ENTIUS**, 1225-72; king of Sardinia, a natural son of Frederick II. and the beautiful Bianca Lancia; b. at Palermo. He fought by his father's side against the Lombards at the battle of Cortenuova before he was 13 years of age, and the following

year was married to Adelasia, the heiress of Sardinia and Corsica, and given the title of king of Sardinia. In May, 1239, he was declared vicar imperial in northern Italy, and commanded the German and Saracen troops in the imperial army; he entered the March of Ancona, and became so formidable a foe to the papacy, that the distinguished soldier-cardinal, John of Colonna, was sent against him. Gregory IX. excommunicated Frederick and his son before the end of the year; and a crusade against them was preached soon afterwards. In 1241, the command of the fleet having been intrusted to Enzo, he gained a splendid victory over the Genoese, sinking three of their vessels and capturing 19. Amongst the captives were three cardinal-legates, and many bishops and archbishops; the booty included the large sums of money which the notorious cardinal Otho had just collected in England. After the death of the pope (August), Enzo was sent with a large army to aid his brother Conrad, king of the Romans, against the invading Tartar hosts; the victory won by the two brothers near the river Delphos finally delivered Europe from the presence of these desolating hordes. Enzo was afterwards sent into Lombardy, which was for several years the scene of his chief exploits. In 1245, he was again excommunicated by Pope Innocent IV., and in 1247 he besieged Parma, but was forced to retire. He then besieged Colonna, and in 1249 took the castle of Arola, but, on May 26 of the same year, he was taken prisoner at Fossalta by the troops of Bologna and consigned to perpetual imprisonment. "A captive at the age of 24," says Dean Milman, "this youth, of beauty equal to his bravery—the poet, the musician, as well as the most brilliant soldier and consummate captain—pined out 23 years of life, if not in a squalid dungeon, in miserable inactivity."

E'OCENE (*eos*, dawn, and *kainos*, recent), a term introduced by Lyell to characterize the lower tertiary strata, from the idea that the fossil shells of that period contain an extremely small proportion ($3\frac{1}{2}$ per cent.) of living species. He accordingly looks upon these beds as indicating the dawn of the existing state of the testaceous fauna—no recent species having been detected in the older rocks. The gradual approximation of the living inhabitants of the globe to the present forms is the chief characteristic of the E. and newer deposits. The E. beds rest on the chalk. Like the other tertiary strata, these deposits occupy small and detached areas when compared with the older measures. It is not difficult to determine the relative position of primary or secondary strata, because of the great extent of particular beds, being frequently continuous over extensive districts. But tertiary deposits are more isolated, and occur in smaller and more detached patches; hence it is difficult to determine the contemporaneity of the sections of the various periods, occurring as they do in different isolated localities. Their relations must be determined from the petrological structure of the beds, which, however, is very inconstant, or from the more satisfactory evidence derived from their fossiliferous contents.

In the following table are given the generally received divisions of this period, with the maximum thickness (in English ft.) of the English strata, and the French and Belgian equivalent beds:

| | | | |
|----------------------------|-----------------------------|------|--|
| MIDDLE Eocene Eocene | 1. Hampstead series..... | 175 | { Calcaire lacustre supérieur, and Grès de Fontainebleau.—Rupélien. |
| | 2. Bembridge series..... | 115 | { Gypseous series of Montmartre, Calcaire lacustre moyenne, and Calcaire siliceux.—Tongrien. |
| | 3. Osborne series..... | 70 | { Grès des Beauchamp. |
| | 4. Headon series..... | 182 | { Sables moyennes, Calcaire grossier, and Lits coquilleux.—Laeckenien and Bruxellien. |
| | 5. Bagshot series..... | 1270 | { Wanting in France.—Ypresien. |
| MIDDLE Eocene Eocene | 6. London clay series..... | 480 | { Argile plastique et lignite.—Landenien supérieur. |
| | 7. Plastic clay series..... | 160 | { Wanting in France.—Landenien inférieur. |
| | 8. Thanet sands series..... | 90 | |
| Total thickness..... | | 2542 | feet. |

In our own country, the eocene strata extend from New Jersey to the Mississippi River, forming a belt parallel with the Atlantic and Gulf coasts; and in the interior are noted in Wyoming and Idaho; but not upon the western sea-coast. The eastern strata are divided into (1) the Claiborne beds; (2) the Jackson beds, and (3) the Vicksburg beds. They contain fossils in the shape of marine mollusks, fruits, and leaves. In the west, they exhibit the remains of a group of mammalia named by Prof. O. Marsh *dinocerata*, of huge size, horned, and with enormous teeth. The leaves and fruits are thought to indicate an original tropical climate. Some of these have been found in Vermont, and some as far west as the Mississippi. The most recent bed is the Vicksburg.

EOLIAN ACCUMULATIONS. A name applied by geologists to accumulations apparently formed by the action of the winds.

EOLIAN HARP. See **ÆOLIAN HARP.**

EOLIPILE, a hollow metallic ball from which, when heated, steam issues by orifices in two tubes, so as to turn the ball. It was invented by Hero of Alexandria. See **HERO**, **STEAM-ENGINE.**

EOLUS. See **ÆOLUS.**

EON, or **EUDO DE STELLA**, a religious fanatic of Bretagne in the 12th c., who claimed to be the final judge of mankind. He opposed the hierarchy of the church, and taught that the only true baptism was the baptism of the Holy Ghost given by the laying on of hands. He was believed to have miraculous power, and gained many followers. He was opposed publicly by the cardinal-legate Albericus, and in a book by archbishop Hugo of Rouen. Some of his disciples were burned to death for their heresy. In 1148 he was captured, with some of his leading adherents, and tried before the synod at Rheims, but escaped execution because thought insane. After his death his sect soon died out.

EON DE BEAUMONT, **CHARLES GENEVIÈVE LOUIS AUGUSTE ANDRÉ TIMOTHÉE D'**, known as the *Chevalier d'Eon*, was b. at Tonnerre, in Burgundy, in 1728, studied law, and became an advocate. He attracted the notice of the prince of Conti by some political writings; and in 1755 was introduced by the latter to Louis XV., who employed him in diplomatic missions to Russia and Austria. After serving a short time in the army, not without distinction, he was sent to London in 1761 as secretary of embassy, and shortly after was made minister-plenipotentiary. Becoming the victim of a court cabal, however, which deprived him of his office, he took his revenge by publishing his secret correspondence with the French court, which contained, among other things, libels on various persons. For one of these, he was prosecuted in London; and to avoid judgment, fled to the continent. He, however, returned to England again; but, on the death of Louis XV., the French ministry deemed it prudent to recall him, as they were afraid he might betray their secrets to the English government, which made him brilliant offers. The pretext laid hold of for this purpose, was the scandal excited in London by his having assumed the garb of a woman, which he had done at the request of Louis, the better, it may be presumed, to hide his designs as a "secret agent." On his return to France, however, Eon was very favorably received; and Louis XVI. even ordered him to make use of the feminine garb in future. In 1783, he again proceeded to London, not, however, in any visible official capacity; and, though dressed as a woman, gave lessons in fencing, of which art he was a complete master. On the outbreak of the French revolution, he hastened home, and offered his services to the nation; but as nothing came of his offer, he finally returned to London, where he sank into the greatest misery, and d. 21st May, 1810. An examination of Eon's remains by Mr. J. Copeland, a surgeon, settled the question of his sex, and put an end to the curiosity of the English public. His writings appeared at Amsterdam 1775, under the title of *Loisirs du Chevalier d'Eon*. The *Mémoires* which bear his name are not genuine.

EOO'A, or **MIDDLEBURG**, one of the Friendly or Tonga islands, is 30 m. in circuit, and contains 300 inhabitants. It is in lat. 18° 19' s., and long. 175° 37' west. The surface, which is rocky and barren, rises 600 ft. above the sea. The group, as a whole, was discovered by Tasman in 1643.

EOS. See **AURORA**

ÉÖTVÖS, **JOZSEF**, a highly distinguished Hungarian author, was b. 3d Sept., 1813, at Buda; educated at home by a tutor of republican sentiments, and studied philosophy and jurisprudence at the university of Pesth during the years 1825-31. He became an advocate in 1833, but soon resolved to devote himself exclusively to literature, in which field he had already won a great reputation by his comedies *Kritikusok* (The Critics) and *Házasságok* (The Weddings), and also by his tragedy *Boszú* (Revenge). After his return from a journey through Germany, France, England, Switzerland, and the Netherlands, he published his *Prison Reform* (*Gefängnisreform*, Pesth, 1838), which was instrumental in bringing about many wholesome improvements in regard to prisons. This was followed (1838-41) by his novel entitled *The Carthusian*, which excited great interest, and was pronounced to be one of the best productions of Hungarian literature. E. now began to distinguish himself in politics. When the liberal party split, in 1844, into municipalists and centralists, he became one of the most eloquent advocates of the policy of the latter party, and wrote numerous articles in favor of it in the *Pesti Hírlap*, which are marked by varied learning, fullness of thought, and elegance of expression. They were issued in a collected form at Leipsic in 1846, under the title of *Reform*. The *Village Notary* (*A' Falu' Jegyzője*, 3 vols., Pesth, 1844-46; English by Otto Wenckstern, 1850; German by Mailath) is a work of the highest order of merit. For variety of incident, easy vigor of style, humor, liveliness, and freshness of descriptive power, it has been pronounced equal to the best of the *Waverley Novels*. It was followed in 1847-48 by his *Magyarország 1514-ben* (Hungary in 1514), which describes the insurrection of the peasants that happened in that year in a masterly style. When the revolution of 1848 broke out, E. was appointed minister of public instruction, but soon became aware of his own incapacity for the work of a practical statesman, and abandoning his country, which he deemed it impossible for him to serve, retired for some time to Munich, where he employed himself exclusively in literary pursuits. The most important fruit of his residence here was *Der Einfluss der Ideen des 19 Jahrh. auf Staat und Gesellschaft*. In 1851, E. returned to Hungary. In 1859, he published anonymously his *Garantien der Macht und Einheit Oesterreichs*. In 1867, he was appointed minister of worship and education, and in that capacity engaged actively in the work of reform. He d. at Pesth on the 3d of Feb., 1871.

EOZOIC PERIOD. See **ARCHÆAN PERIOD.**

EOZO'ON, supposed by some paleontologists to be one of the oldest geological representatives of animal life, and by others held not to be an animal. It was a huge mass of lower organization than the sponges or protozoa, and belonged (if to animals) to the *Foraminifera*. It was jelly-like, without definite organs, but probably with power to secrete a calcareous shell. Remains have been found in Canadian rocks, whence the name *Eozoon Canadense*. See **LAURENTIAN SYSTEM.**

EPACRIDA CEE, a natural order of exogenous plants, consisting of shrubs and small trees, which, both in appearance and in botanical characters, much resemble the *Ericææ*, or heath family. The most important distinguishing structural character is indeed found in the simplicity of the anthers, which are one-celled, open longitudinally, and are destitute of appendages. The flowers of the E. have generally a tubular corolla, dividing into five—rarely four—segments; which, however, sometimes become separate petals. The calyx is persistent, often colored, has the same number of segments with the corolla, and is surrounded with small bracts. The stamens are fewer than in the *Ericææ*, usually equal in number to the segments of the corolla, and alternate with them. The fruit is sometimes a capsule, sometimes a berry, sometimes a drupe. The leaves are simple, generally alternate, often crowded; the flowers in spikes, in terminal racemes, or axillary and solitary.—About 400 species of E. are known, all natives of the Indian archipelago, the South Sea islands, and Australia; in which regions they seem to occupy the place of the heaths of other parts of the world. Some, particularly of the genus *epacri*, are well-known ornaments of our green-houses, and are flowering shrubs of great beauty. Some produce edible berries resembling the cranberry. See **CRANBERRY.**

E'PACT, in chronology, is the excess of the solar month above the lunar synodical month; or of the solar year above the lunar year of twelve synodical months; or of several solar months above as many synodical months; or of several solar years above as many periods, each consisting of 12 synodical months. The menstrual E. is the excess of the civil calendar month above the lunar month. For a month of 31 days, this E. is 1 day 11 hours 15 minutes 57 seconds, if we suppose new moon to occur on the first day of the month. The annual E. is the excess of the solar year above the lunar. As the Julian solar year is (nearly) 365 days, and the Julian lunar year is (nearly) 354 days, the annual E. is nearly 11 days. The E. for two Julian years is, therefore, nearly 22 days; for three years, 33 days; and so on. When, however, the epact passes 30 days, 30 falls to be deducted from it, as making an intercalary month. For three years, then, the E. is properly 3; and for 4 years, adding 11 days, it is 14 days; and so on. Following the cycle, starting from a new moon on the 1st of Jan., we find that the E. becomes 30 or 0 in the 19th year. The E. for the 20th year is again 11; and so on. The years in the cycle are marked by Roman numerals, I. II. III., etc., called the golden numbers; and a table of the Julian epacts exhibits each year in the cycle with its golden number and epact. As the Gregorian year (see **CALENDAR**) differs from, and is in advance of, the Julian by 11 days (the number lost on the Julian account before the Gregorian computation of time was introduced in England), and as 11 days is the difference between the solar and lunar years, it follows that the Gregorian E. for any year is the same with the Julian E. for the year preceding it.

EPAMINON DAS, the most eminent of Theban generals and statesmen, and one who for a long period elevated his country to the highest point of honor and prosperity, was b. 414 B. C. He was descended from an ancient but impoverished family, and led a retired life till his 40th year, profiting by the instructions of Lysis the Pythagorean, who inspired him with enthusiasm for the elevated ideas which it was the object of his life to realize. E. first becomes prominent during the period when the Lacedæmonians garrisoned the citadel of Thebes, and kept the inhabitants in subjection. Though he took no part in the desperate but successful stratagem by which his fellow-citizens recovered the *Cadmeia* in 379 B. C., he stepped forward immediately after into the ranks of the patriots; and when sent to Sparta in 371 B. C., along with several others, in order to negotiate a peace between the two countries, E. displayed as much firmness and dignity as eloquence in the debate which ensued upon the question whether Thebes should ratify the treaty in the name of all Bœotia, the result of which ratification would have been equivalent to a recognition of her claim to supremacy over the Bœotian towns. To this the Lacedæmonians demurred, and the war was again resumed; E. was appointed commander-in-chief; and, in conjunction with his friend Pelopidas, with an army of 6,000 men, defeated double that number of the enemy at Leuctra (371 B. C.). Two years later, he and Pelopidas marched into the Peloponnesus, incited several of the allied tribes to fall away from Sparta, and then turned his arms against that city, which, however, was bravely defended by Agesilaus. On his return to Thebes, E. was accused of having violated the laws of his country, by retaining the supreme power in his hands beyond the time appointed by law; but was acquitted in consequence of his open and animated defense. In the spring of 368 B. C., the war was renewed with increased fury between Thebes and Sparta, and E. once more marched into the Peloponnesus, but did not accomplish much; and on his return home, received a check from Chabrias at Corinth. To atone for this unsuccessful undertaking, he advanced with 33,000 men into Arcadia,

and joined battle with the main body of the enemy near Mantinea, in the year 362 B.C. E., at the head of his troops, succeeded in breaking the Spartan phalanx, but was mortally wounded in the breast by a javelin. Being told by the physicians that he would die as soon as the weapon was extracted, on receiving intelligence that the Bœotians had gained the victory, he is said to have torn out the javelin with his own hand, exclaiming: "I have lived long enough." His moral purity, justice, and clemency are extolled by the ancients as much as his military talents; and it is expressly recorded of him, that he never told a lie, even in jest. Compare Bauch, *Epaminondas und Thebens Kampf um die Hegemonie* (Breslau, 1834); Pomtow, *Das Leben des E.* (1870).

EPANADIPLOSIS. See RHETORIC, FIGURES OF.

EPANALEPSIS. See SYNTAX, FIGURES OF.

EPANASTROPHE. See SYNTAX, FIGURES OF.

EPANOME'RIA, a town in Santorini, one of the Grecian islands, built on a steep promontory, so that the houses are ranged in terraces one row above another to the number of 15 or 20. Some are excavations in the rock, and the lowest are 400 ft. above the sea. The place is reached by a winding pathway cut in the face of the cliff, on the summit of which are many windmills.

EPANORTHOSIS. See RHETORIC, FIGURES OF.

EP'ARCH, the governor of a province in ancient Greece, or prefect of a region under the rule of Rome. In modern Greece a province of the kingdom is called a nomarchy, and a subdivision of a nomarchy an eparchy. In Russia the term has an ecclesiastical use, denoting the diocese or archdiocese of a bishop or archbishop.

EPAULEMENT (from the French *épaule*, shoulder), in siege-works, is a portion of a battery or earthwork. The siege-batteries are generally shielded, at one end at least, by epaulements, forming an obtuse angle with the main line of the battery. The object is to protect the guns and gunners from a flanking fire. The name is often given erroneously to the parapet of the battery itself, but it applies properly to the flanking return only. Sometimes the whole of a small or secondary earth-work, including the battery and its flanks, is called an E.; and sometimes the same name is given to an isolated breast-work intended to shield the cavalry employed in defending a body of besiegers.

An *épaule* is the shoulder of a bastion, where one of the faces and one of the flanks meet; and this points to the proper meaning of E., as a shoulder or flanking work.

EP'AULET, from the same French source as epaulement, is a shoulder-knot worn by commissioned officers in the naval profession, both as an ornament and a distinction. In the British navy, the officers of and above the rank of lieutenant wear epaulets of gold lace, one on each shoulder, sub-lieutenants wearing one only. Ranks and degrees are marked in a very systematic way by means of crowns, anchors, and stars worked in silver on the E., and also by the size of the cords of the E. itself. This decoration was formerly universal in the British army, officers wearing those of gold, men of worsted; but they were abolished during the Russian war, in consequence of the danger to which officers thus easily marked out were exposed. It is retained by the French army alone of the armies of the great powers.

EPÉE, CHARLES MICHEL, ABBÉ DE L', one of the founders of the system of instruction for the deaf and dumb, was b. at Versailles, 25th Nov., 1712. He studied for the church, and entering into holy orders, became a preacher and canon at Troyes, but eventually, on account of his Jansenist opinions, was deprived of this appointment. He now lived in retirement in Paris. In the year 1755, he first began to occupy himself with the education of two deaf and dumb sisters; and, as he asserts, without any previous knowledge of Pereira's efforts in the cause, invented a language of signs, by which persons thus afflicted might be enabled to hold intercourse with their fellow-creatures. His first attempt being crowned with success, he determined to devote his life to the subject. At his own expense, he founded an institution for the deaf and dumb, and labored with unwearied zeal for its prosperity. His favorite wish, however, the foundation of such an institution at the public cost, was not fulfilled till after his death, which took place 23d Dec., 1789. He wrote a work, entitled *Institution des Sourds et Muets* (2 vols., Paris, 1774), which afterwards appeared in an improved form under the title, *La Véritable Manière d'Instruire les Sourds et Muets* (Paris, 1784).

EPEI'RA, a genus of spiders, the type of a family called *epeiridae*. They are of those spiders which have only a pair of pulmonary sacs and spiracles; construct webs with regular meshes, formed by concentric circles and straight radii; and are furnished with a pair of almost contiguous eyes on each side, other four eyes forming a quadrangle in the center. Many of them are remarkable for the beauty of their colors and of their forms. Several species abound in our gardens, particularly in autumn. *E. diadema* is one of the largest British spiders. It is found in moors, the borders of woods, etc.; but it is in tropical countries that the *epeiridae* exist in greatest numbers, and attain the greatest size and beauty, extending from branch to branch their lace-work, remarkable for gracefulness of design. The net, when loaded with wings, wing-covers, and limbs of insects that have been preyed upon, is often loosened, and falls down upon the central nest or den of the spider; and successive nets thus falling down, form at last a ball sometimes as large as a man's head. Some of the spider cords, carried horizontally

from tree to tree at a considerable height from the ground, "are so strong as to cause a painful check across his face when moving quickly against them; and more than once," Sir J. E. Tennent says, "in riding I have had my hat lifted off my head by a single thread."—Tennent's *Ceylon*.

ÉPERGNE. (Fr., derivation uncertain.) A term applied to an ornamental piece intended for the centre of a dinner table. It is sometimes merely ornamental, as a group of figures; but when complete it has one or more receptacles which are detachable, and serve to contain flowers, fruits, bonbons, and other articles of dessert. It varies in design, and is sometimes in the form of a standard, diminishing in size toward the top, or it may be of a low design. Épergnes are usually of silver or glass, but may be of gilt or bronze.

EPERÏES (Lat. *Fragopolis* or *Eperesinum*; Hung. *Eperjes*, Slovak *Pressova*), an old t. of Hungary, in the co. of Saros, of which it is the capital, is agreeably situated on the left bank of the Tarcza, about 150 m. n.e. of Pesth. It is surrounded with walls, is the seat of a bishop, and contains some houses of the 15th and 16th centuries, built in the style of those in Naples, with which E. was much connected in the middle ages. Its principal buildings are the church of St. Nicholas, the communal college, with 500 students and a library consisting of 14,000 volumes, and the county hall. It has manufactures of earthenware and of linens and woollens, and has some trade in linen goods, corn, and Tokay wine. In the vicinity are the Sovar saltworks, which produce 5,000 tons of salt annually. Pop. in '80, 10,139, almost wholly Slavonic.

EPERNAY, a t. of France, in the department of Marne, is the headquarters of the *vins de Champagne*, and is situated in the midst of a rich vine-growing district, on the left bank of the Marne, 19 m. w.n.w. of Chalons. It is well built, clean, and well paved. Its environs consist, for the most part, of elegant villas, with vaults attached, belonging to the Champagne wine-merchants. E. manufactures large quantities of earthenware from a clay obtained in the neighborhood, and called *terre de Champagne*; also hosiery, refined sugar, and leather. It has a brisk trade in bottles, corks, wire, Champagne wines, etc. Pop. of commune '91, 18,361.

EPHAH, a measure of capacity for dry goods in use among the Hebrews. It contained three English pecks and three pints.

EPHEMERA (Gr. lasting for a day), a Linnæan genus of neuropterous insects, now forming the family or tribe *ephemeridæ*. They are allied to the *libellulidæ*, or dragon-flies, but differ from them in many very important respects. They have received their name, to which corresponds the English DAY-FLY, sometimes also applied to them, from the brief duration of their existence in the perfect state, in which, very unlike the dragon-flies, they are believed to take no food, merely propagating their species, and dying. From the season of the year in which they begin to be seen, some of them are also called MAY-FLY; and by this name are well known to anglers, who use them, and artificially imitate them as excellent lures for trout. The eggs of the ephemera are also a favorite food of fishes; they cohere together in a gelatinous mass. The larvæ and pupæ are aquatic, and in these states the ephemera have a much longer life than in their perfect state, extending even to years. The larvæ and pupæ are sufficiently voracious. The abdomen of the larva is furnished on each side with a set of leaflets, which serve instead of gills for respiration, and are also used in locomotion, although there are 6 ft. attached to the thoracic segments. The pupæ differ little from the larvæ except in having rudimentary wings inclosed under scales. Both larvæ and pupæ have the abdomen terminated by two or three jointed filaments, which the perfect insect also has, sometimes very long. The body of the perfect insect is soft and slender; the wings resemble in form those of dragon-flies, but are soft and filmy; in repose, they are elevated vertically above the body; the second pair of wings are much smaller than the first, and in some species are altogether wanting; the organs of the mouth are so soft and small as not easily to be discerned, and to be apparently unfit for any kind of use. Ephemera, in their larva and pupa states, live chiefly under stones in water, or in burrows which they make in the banks of streams. When ready for their final change, they creep out of the water to undergo it on some plant or other object by the water-side, generally towards sunset on some fine day of summer or autumn. After having attained their winged state, however, they cast off a complete slough or envelope, so perfect, that it exhibits even the limbs, abdominal filaments, and antennæ; and these "ghost-like exuvie" are sometimes so abundant in the neighborhood of streams, as to cover in "a pearly layer" the hat and basket of the angler. The multitudes of ephemera are often very great, filling the air as a cloud; nay, so abundant are they at times, that their bodies have been known to cover the ground in certain districts of France, and have been gathered in cart-loads to be used as manure. See illus., BEETLES, ETC., vol. II., p. 386, fig. 19.

EPHEMERA, or FEBRIS DIARIA in Latin (from Gr. *epi* and *hemera*, on a day), a fever which lasts only a single day, or part of a day, and is generally dependent on some slight local irritation. It hardly requires any other treatment than the removal of the cause, if known.

EPHEMERIS (Gr. "for the day") is a name applied to almanacs from their containing notices for each day. It is mostly confined to astronomical tables giving the daily

places of the sun, moon, and planets, and other phenomena of the heavens. Such tables have become common since the days of Kepler. The first were published by Purbach for the years 1450-61. Those of Regiomontanus, for 1474, were much more accurate, and his ephemerides met with universal acceptance. Similar publications were afterwards made by Leovitius, Origanus, Kepler, and others. The most important works of the kind at present are the French *Connaissance des Temps*, the English *Nautical Almanac*, the Berlin *Astronomisches Jahrbuch*, and the *American Ephemeris and Nautical Almanac*.

EPHESIANS, EPISTLE TO THE, is now universally admitted to have been written by the apostle Paul. It is expressly ascribed to him by Ignatius (if indeed any writings attributed to him are genuine), who was contemporary with Paul; is alluded to by Polycarp, a friend of the apostle John, and cited by Irenæus, Clement of Alexandria, Tertullian, Origen, and many subsequent writers. Some critics have maintained that it was not addressed to the Ephesians, but either to the Laodiceans or to several churches in common, of which Ephesus may have been one. The reasons which they assign for this opinion are: 1. That Marcion, a heretical writer of the 2d c., asserts that in his copy of the epistle the reading was "in Laodicea," and not "in Ephesus." The answer to this is that Marcion is known to have altered the text in other instances to suit his own views, he is not to be trusted, especially when all known ancient manuscripts and all ancient versions read "in Ephesus." 2. That as Paul directed the Colossians to read the epistle from Laodicea, he must have written an epistle to Laodicea, which is either this so-called epistle to Ephesus or else has been lost. To this the answers are: (1) If he did write to Laodicea, it may have been a letter designed for local and temporary use only. As Christ said and did many things which he did not design to have recorded in the small book of the New Testament, why may not an apostle have written some things which were not to have a place there? (2) Paul charged the Colossians to let the epistle which he sent them be read by the Laodiceans; but why would he have wished this so earnestly if at the same time he had written to Laodicea this "epistle to the Ephesians" (which so greatly resembles that to the Colossians), and had intrusted both to the same messenger to be delivered at about the same time? (3.) It is said that if the epistle had been written to the Ephesians, among whom Paul had spent three years of most loving and successful ministry, it could not have been so general in its style, and would have contained personal salutations at the close. To this the answers are: (1) This epistle and that to the Colossians, written at the same time, both show that Paul's thoughts were intent on Colosse, Laodicea, Hierapolis, those whom he had never seen, the Gentiles at large, and God's eternal purpose with reference to them all. In all that he then wrote, therefore, themes of general and permanent interest might naturally prevail to the exclusion of personal and transient things. (2) At the close of the epistle he expressly says that he has committed all matters of a personal nature between himself and his readers to the beloved and faithful brother who was the bearer of the epistle, and whom he sent to them for the very purpose of making them acquainted with his condition and of comforting their hearts. Such provision having been made for loving salutations and all other particulars which his former relations to the Ephesians would prompt, the entire absence of them from the epistle itself is explained.

The doctrinal part of the epistle contains thanksgiving to God for the revelation of his eternal purpose of grace to men; prayer that Christians may receive the full measure of the blessings provided for them; the native character of mankind as dead in sins; regeneration by the grace of God, and the benefits, present and future, resulting from it; salvation by divine grace and not by human works; good works the fruit of regeneration; privileges resulting from the reception of salvation by grace; statement of God's purpose to receive the Gentiles among his people; repeated prayer that Christians may receive the fullness of the blessings provided for them; renewed ascriptions of perpetual glory to God in the salvation of men. The practical part consists of exhortations to Christian unity, progress in the new life, general holiness of conduct and heart, the particular virtues of truthfulness, self-control, honesty, purity in words and deeds, sobriety, cheerfulness, fidelity in the relations of wives and husbands, children and parents, servants and masters, and strenuous maintenance of the spiritual warfare, by strength to be obtained from God and under the protection of the armor which he provides.

EPHESUS, one of the twelve Ionic cities of Asia Minor, was situated in Lydia, near the mouth of the river Caystrus, in the midst of an alluvial plain. It does not appear to have been as old as the Trojan war, but its primitive history has been confused by myths. It bore a great variety of names at different times, the principal of which, besides E., were Ortygia and Ptelea. According to Strabo, it was founded by Androclus, son of Codrus, and this is the most probable of the accounts which have come down to us, though others held to the tradition of its Amazonian origin. It was long before E. acquired any political importance, in spite of being a sacred city from an early period. Subdued first by the Lydian, and next by the Persian kings, it was

included, after the death of Alexander the Great, in the territories of Lysimachus (281 B.C.), by whom it was greatly strengthened. Ultimately, it came into the possession of the Romans; and in the time of Augustus, when Strabo wrote, it was "the greatest place of trade of all the cities of Asia w. of the Taurus." This was also its condition when visited by St. Paul, who resided here three years; but the destruction of its great temple by the Goths, in 260 A.D., gave it a blow from which it never recovered. In 341, A.D., it was the scene of the *third* general council of the Christian church. Its general history, while a city of the Byzantine empire, was unimportant, and before the days of Tamerlane it had almost completely perished.—The ruins of E. comprise a stadium 687 ft. long, fragments of a great theater (alluded to in the account of St. Paul's preaching in the city), of an odeum or music-hall, and of various walls and towers, belonging to the Greek, Roman, and Byzantine eras. Near the western extremity of the town are also some massive structures, which have since 1868 been carefully excavated, sometimes from beneath 18 ft. of soil. It is now certain that these stand on the site of the famous *temple of Diana*. This marvelous building, one of the seven wonders of the world, was originally built by Chersiphron; but after its destruction by Herostratus on the night (as is said) when Alexander the Great was born (356 B.C.), it was rebuilt by the inhabitants in a style of greater splendor than before, the very women contributing their ornaments to secure the necessary funds; yet, notwithstanding this enthusiasm, more than 200 years elapsed before the new edifice was completely finished. It was the largest Greek temple ever constructed. Its length was 425 ft., its width 220, the number of its columns 128, of which 36 were carved, and their height 60 feet. It had an area more than four times that of the Parthenon at Athens, and even the Olympeum was only about two thirds as great. But even more wonderful than the temple itself were the numberless statues and pictures which it contained, executed by the best masters of Greece. The altar of the goddess was principally adorned with the works of Praxiteles. Plundered of its treasures by Nero, and burned (as has been mentioned) by the Goths, it was most likely finally destroyed by the iconoclasts, in the reign of Theodosius I., who issued his celebrated edict against the ceremonies of the pagan religion 381 A.D. The site of E. is now occupied by some wretched villages, the principal of which is Ayasaluk.—Certain cabalistic words or sayings are said to have been inscribed on the figure of Diana, which being copied and carried about as charms, became known as *Éphesæ litoræ* (Mason's *Anatomie of Sorcerie*, 1612).

EPHOD, a vestment worn by the Jewish high-priest over the *mêil* or second (purple) tunic. It consisted of two shoulder-pieces, one covering the back, the other the breast and upper part of the body, not unlike the Greek *epônīs*. Two onyx stones set in gold fastened it on the shoulders, and on each of the stones were engraved the names of six tribes, according to their order. The material of which the E. was wrought was extremely costly and magnificent: "gold, blue, purple, crimson, and fine twined linen." A girdle or band, of one piece with the E., fastened it round the body. Just above this girdle, in the middle of the E., and joined to it by little gold chains, rings, and strings, rested the square oracular breast-plate with the mysterious *Urim and Thummim*. See also **HIGH-PRIEST** and **URIM AND THUMMIM**.

Originally intended to be worn by the high-priest exclusively, ephods of an inferior material seem to have been in common use in later times by the ordinary priests. Even David, when bringing the ark back to Jerusalem, appeared in one. There is also mention made of an E. in several passages of the books of Judges and Samuel, where the word must needs stand either for the *whole* priestly apparatus of an illegal service, or simply for a statue or an idol. The Talmud understands this E. to have been a colossal shoulder vestment of gold, to which divine honors were rendered.

EPHORI (Gr. "overseers"), an order of magistrates in ancient times which appears to have originated at Sparta, and to have been peculiar to the Doric governments. When or by whom the E. were first instituted, is a point of great uncertainty. Herodotus attributes their creation to Lycurgus, and Aristotle to Theopompus (770–720 B.C.). Their duty was to superintend the internal administration of the state, especially affairs of justice, for which a particular building was assigned them, called the Ephorion. One of their most important functions was the oversight, at least in part, of the education of youth, for we are told by Athenæus that they inspected the clothing and bedding of the young men. The E. were five in number; they were elected by and from the people—on which Aristotle observes, that through them the *demos* enjoyed a participation in the highest magistracy of the state—and held their office only for one year. Their influence gradually increased, for their powers were so ill defined that it was difficult to say what was *not* under their cognizance and authority. Cicero draws a comparison between the ephoralty of Sparta and the tribunate of Rome, which is not altogether unwarranted by the facts of the case. Ultimately, the kings themselves became subject to the supervision of the ephori. Cleomenes, for example, was brought before them for bribery; Agesilaus was fined, and Pausanius imprisoned; and in extreme cases they could prefer charges against them, and have them tried before the supreme criminal court. They also transacted the negotiations with foreign powers, subscribed treaties, raised troops, "intrusted the army to the king or some other general," and, in fact, acted as the executive of the state. Muller regards the ephoralty as "the principle

of change in the Spartan constitution, and, in the end, the cause of its dissolution." In the hands of the E., the constitution of Sparta certainly ceased to be a genuine aristocracy, and became a sort of oligarchy; but this point is involved in much obscurity and perplexity. Their authority, however, was at last destroyed by Agis and Cleomenes, who murdered the E. for the time being, and restored the old Spartan constitution (225 B.C.).

EPHRAEM SYRUS, one of the most celebrated and prolific ecclesiastical writers of the Syrian church. Several accounts of his life have been handed down to us, but they all bear more or less such a legendary character, that the real facts to be gathered from them are but scanty. It appears, then, that Ephraem (Heb. *Ephraim*) was born in the early part of the reign of Constantine the Great, "somewhere between the Euphrates and Tigris," most probably at Nisibis. His parents were, according to some, heathens; and Ephraem, repudiating their idolatry at an early age, had to leave their roof. Jacob, bishop of Nisibis, took care of the boy, and undertook his education. His progress in learning was so satisfactory that the bishop was soon able to make him teacher at his own school; and when in 325 A.D. Jacob went to the council of Nicaea, Ephraem accompanied him thither. In 363, Nisibis was ceded by Jovinian to the Persians, and Ephraem first retired into Roman territory, then went to Anid, his mother's birthplace, and finally settled in Edessa (Orfa), where he remained until his death. He is said to have been so poor when he first arrived at Edessa, that he was obliged to take service at a public bath, but he soon became acquainted with hermits of the neighborhood, and adopted their habits; he retired into a cave near the town, and led the life of a recluse. But so great were his piety and asceticism, as well as his readiness to help the poor and tend the sick, that he was looked upon as a saint, and his day is still celebrated, at different dates, in various churches. Among his usual denominations, more especially referring to his teachings and writings, are "Prophet of the Syrians, Column of the church, Harp of the Holy Spirit," etc.; and his name is never mentioned without the "Mor" or "Mari" (Lord, My Master) being prefixed. But for all that, he had no lack of enemies. His burning zeal for preaching and converting led him to attack most fiercely almost every one beyond the pale of his peculiar creed. He spoke and wrote unceasingly against Idolaters, "Chaldees," Jews, and heretics of all kinds, especially Arians, Sabellians, Manichæans, Novatians, etc. Towards the end of his life, he paid a visit to Basil the great, in Cappadocian Cæsarea, who could not prevail upon him to accept of any higher office in the church than a deanery, though he spared no effort to make him bishop. Returned to Edessa, he found plague and famine raging there, and to his exertions for the relief of the sufferers his death is attributed by some. He expired in the same year with Basil, in 373, not before having given the strictest injunctions that his burial should be of the very simplest description. With respect to the Testament which he is reported to have dictated in his dying hour—much as it has been used for biographical purposes—we can take no notice whatever of it, as it is entirely spurious.

The visit to Basilus, unimportant as it seems, has been of very great moment. The legend which surrounds this, as all other incidents of his life, with a halo of miracle, records that the two men, although previously ignorant of each other's language, began to speak them fluently at this interview—Basilus Syriac, and E. Greek. This wonderful circumstance first induced the learned to enter upon the question, whether E., half of whose voluminous works are in Greek, did really understand that language; and further, whether he understood any language but his own, Syriac. If he did not, what view was to be taken of his commentaries on the Bible, of which the Hebrew and Greek texts, as well as the Septuagint and the Greek fathers, must have been a sealed book to him. There were, and are still, great differences of opinion on these points, but it is generally taken for granted now, that he did not understand any language but his own; that he made use of the common Syriac version, the Peshito; that his grammatical and linguistic notes are taken from different Syriac commentaries, and that the Greek portion of his works consists partly of translations made from his Syriac after his death, or even during his lifetime, and partly of interpolations. Both the praise and the blame which have been indiscriminately bestowed upon him as a writer are exaggerated. His chief merit lies in the glowing fervor and the deep piety which he infused into all he wrote, more particularly into his elegiac hymns. Diction and form are poetical throughout, and when not soaring into the infinite, of no mean beauty. The effect is heightened by the matchless simplicity and awing grandeur of the Syriac idiom.

We will now enumerate his principal works and their editions. Those (under his name) in Greek, consist of sermons or homilies, and treatises of an exegetic, dogmatic, and ascetic nature. Photius records that he wrote more than a thousand such sermons; Sozomenos speaks of "300 myriads;" but, as we said before, of those that have come down to us, some are spurious, and others at least suspicious. Gerhard Vossius translated 171 treatises from Greek MSS. found in Italian libraries, into Latin, and published them at Rome, 1589-98, in 3 vols. (There is but one piece in them translated from the Syriac.) They were reprinted in Cologne in 1603, 1619 (1675), and also in Antwerp, in 1619. The first Greek edition appeared in Oxford in 1709, edited from 28 Oxford MSS., by E. Thwaites. The most important of his Syriac works are, besides an infinite variety of homilies, sermons, poems, etc., his commentaries, or rather scholia, on parts

of the Old Testament. Their value to us, however, is limited to their aiding us in explaining and fixing some readings of the Peshito (see PESHITO), and in enriching our critical apparatus. That he also commented on the Gospels is certain, but no MS. has been found as yet, not even in a Greek or Arabic translation. As to the songs and prayers in the Syrian liturgy ascribed to E., they are simply composed in his manner, and betray their comparatively recent origin at the first glance. The principal edition of his works in Syriac and Greek was published in 6 vols. in Rome, under the papal authority (1732-1746).

The principal writers on E. are: Sozomenos, *Hist. Eccl.*, iii. 16; Assemani, *Proleg. and Biblioth. Orient.*; Credner, *De Proph. Min. Vers. Syr.* (1827); Lengerke, *Comm. de Ephr. Syr. S. S. Interprete* (Halle, 1828); and *De Ephr. Syr. Arte Hermen.*, etc. (1831). Some tasteful German translations of hymns, by Zingerle, are to be found in the *Zeitschr. d. Deutschen Morgenl. Gesellsch.*, *passim*.

EPHRAÏM, the younger son of Joseph by his wife Asenath, and the founder of one of the twelve tribes of Israel. It is possible that he may have received his name, which signifies "double fruitfulness," from having been born during the seven years of plenty. His grandfather, Jacob, shortly before his death, prophesied the greatness of his posterity when giving him his blessing: "His seed shall become a multitude of nations" (Gen. xlviii. 19). After the Israelites had left Egypt, the tribe of Ephraim numbered 40,500 (Numbers i. 32, 33); but from causes not specified, and not discoverable, it had sunk, 40 years later, on the eve of the conquest of Canaan, to 32,500 (Numbers xxvi. 37). Yet it was under the leadership of an Ephraimite, Joshua, the son of Nun, that the Canaanites were subjugated, and the land possessed. This seems to have given the tribe a much higher influence than might have been expected from its numerical strength. We find Judah and Ephraim classed together as taking their inheritance first (Josh. xv. xvi., etc.). The precise boundaries of Ephraim, as of the other tribes, it is impossible to determine. It occupied the center of Palestine, was bounded on the s. by Dan and Benjamin, and stretched from the Jordan on the e. to the Mediterranean on the west. From scattered notices of the Ephraimites in the earlier annals of the Hebrews, we infer that they were, on the whole, jealous of their brethren. This feeling of dissatisfaction at length broke out into rebellion in the reign of Rehoboam, and the new kingdom of Israel, ruled over by Jeroboam, was for the most part merely the kingdom of Ephraim, for the land which lay to the n. of it could hardly be said to be actually in the possession of the tribes whose names it bore, the original inhabitants keeping stubborn hold of their cities and strongholds. See the article **JEWS**.

EPI, or **GIROUETTE** (Fr.), a species of ornamental ironwork with which the cones of pavilions or pointed roofs are sometimes surmounted in the renaissance style of architecture. One of the finest examples is that which surmounts the Tourelle aux Pastorals at the hôtel de Bourgheroulde in Rouen.

EPICHRMUS, a famous Greek poet, was b. in the island of Cos, in the 5th c. B.C. At first, he studied philosophy under Pythagoras; but a residence at Megara, the native soil of comedy, gave him a taste for that branch of the drama. After the destruction of Megara, in 484 B.C., he removed to Syracuse, where, at the court of Hiero, he spent the remainder of his life. From this circumstance, he is often mentioned by the ancients as a Sicilian. Almost nothing else is known of his personal history except that he died at the age of 90, or as some say, of 97. The date of his death, as of his birth, is unknown. E. is called by Theocritus the father of comedy, and Plato assigns to him a place among comic writers as high as that of Homer among epic poets. He certainly did a good service in excluding, to a large extent, from his dramas the vulgar buffoonery which disgraced all previous comedies, and in introducing a regular plot in which the *comus* or band of revelers sustained the dialogue. None of E.'s works survive entire; but we possess several fragments and the titles of thirty-five. They embraced a wide variety of topics, mythological, social, and political. From one of them, Plautus borrowed the plot of his *Menachmi*, which shows a great amount of constructive skill. The fragments of E. have been collected and edited by H. P. Krusemann (Haarlem, 1834). Compare Lorenz, *Leben u. Schriften des E.* (1864), and Guigniant, *Histoire del a Comédie Antique* (1863).

EPIC POETRY (Gr. *epos*, a word, a discourse, or narrative). The two chief kinds of poetry are E. P. and lyric poetry. E. P. has outward objects for its subject, of which it gives an imaginative narrative. The events themselves may be partly real and partly fictitious, or they may be altogether fictitious. Lyric poetry, on the other hand, sets forth the inward occurrences of the writer or speaker's own mind—his feelings and reflections. No composition, perhaps, answers, in all its parts, to the one of these descriptions, or to the other; but a piece or poem is classed as epic or lyric according to the element that predominates. Under each of these grand divisions, or genera, there are subdivisions, or species. The longer poems of the epic genus embrace an extensive series of events, and the actions of numerous personages. The term *heroic epic*, or *heroic poem*, is properly applied to such works as the *Iliad* and *Odyssey* of Homer, Virgil's *Æneid*, Tasso's *Jerusalem Delivered*, Ariosto's *Orlando Furioso*, and others, which describe the achievements of the gods and heroes of antiquity, or of the little less mythic knights of mediæval chivalry. Poems, again, like Milton's *Paradise Lost* and Dante's

Divina Commedia, are sacred epics. Byron's *Childe Harold*, with the length and narrative structure of an epic, abounds in reflection, sentiment, and satire, and thus is, in substance, as much lyric as epic. Productions like those now named, formed the class of grand epics, or epic poems, by way of eminence. But there are several species of minor poems which, from their nature, must also be ranked as epics. One of these is the *Idyl*, a term applied to what is called *pastoral poetry*, or to descriptions in general of natural scenery, and of the actions and manners of men in calm, ordinary life. Burns' *Cotter's Saturday Night*, Goldsmith's *Deserted Village*, and most of Crabbe's poems, are idyls; so are poetical epistles. The *ballad* (q. v.) is another species of minor epic.

Attempts at epic poetry are now rare, the spirit of the age being against that form of composition. Instead of epic poems, we have *novels*, which, so far as subject is concerned, may be considered as the epics of modern civil and domestic life.

EPICTE TUS, a celebrated disciple of the Stoa, was born at Hierapolis, in Phrygia, about fifty years after the birth of Christ. He was at first the slave of Epaphroditus, a freedman of Nero, at Rome, whose abusive treatment he is said to have endured with the composure characteristic of the set to which he belonged. He was afterwards manumitted, and devoted himself to the Stoic philosophy. Domitian hated him on account of his principles, and banished him, along with several other philosophers, from Rome. E. settled at Nikopolis, in Epirus. Under the pressure of the times in which he lived, his serious moral views received a character rather of self-denial than of energy; to renounce, to endure, and not to set the mind upon anything beyond the power of the individual to attain, being the points chiefly insisted on. His pupil, Arrianus, collected the maxims of E. in the work entitled *Encheiridion* ("handbook") and in eight books of commentaries, four of which are lost. The peculiar excellence of the writings of E. consists in their simple and noble earnestness. The real heartfelt love of good and hatred of evil which we are in the habit of supposing an exclusively Christian feeling, does manifest itself very finely and beautifully in these, yet, as prof. Brandis says, "there is not a trace in the *Epictetea* to show that he was acquainted with Christianity, and still less that he had adopted Christianity, either in part or entirely." Some of his opinions, moreover, are essentially Christian in their nature, though, of course, they are unconnected with the facts of revelation. E. believes in our "resemblance" to God, in our "relationship" to him, and in our "union" with him through the coincidence of the "will" and the "soul;" he recognizes the contest between good and evil, the life-struggle in the heart, the divine life against which the law in the members wars; and he affirms the necessity of "invoking God's assistance in the strife," that the inner life may become pure as God is pure. There are several good editions of the works of E., the most complete of which is that of Schweighäuser (Leip. 1800).

EPICU RUS, AND EPICURE ANISM. Epicurus, an illustrious Greek philosopher, was b. in the island of Samos, 341 B.C., seven years after the death of Plato. His father, Neocles, is said to have been a schoolmaster, and his mother, Chærestrate, to have practiced arts of magic. At the age of 18, he repaired to Athens, where it has been supposed that he may have had for his teacher Xenocrates or Theophrastus, or perhaps both, but he himself used to declare that he was self-taught. Of the older philosophers, he was most attached to Anaxagoras and Democritus, his system of physics being evidently built upon the atomic speculations of the latter. E.'s stay at Athens on this occasion was short. At Mitylene, in his thirty-second year, he first opened a school; and there and at Lampsacus he taught for five years. In 306 B.C., he returned to Athens, and established a school of philosophy in a garden which he purchased and laid out for the purpose. From this circumstance, his followers were called the "philosophers of the garden." Although E. laid down the doctrine, that *pleasure* is the chief good, the life that he and his friends led was one of the greatest temperance and simplicity. They were content, we are told, with a small cup of light wine, and all the rest of their drink was water; and an inscription over the gate promised to those who might wish to enter no better fare than barley-cakes and water. The chastity of E. was so incontestable, that Chrysippus, one of his principal opponents, in order to deprive him of all merit on the score of it, ascribed it to his being without passions. The calumnies which the Stoics circulated concerning him are undeserving of notice, and were at no time generally believed. E.'s success as a teacher was signal; great numbers flocked to his school from all parts of Greece, and from Asia Minor, most of whom became warmly attached to their master, as well as to his doctrines, for E. seems to have been characterized not less by amiability and benevolence than by force of intellect. He died 270 B.C., in the seventy-second year of his age.

E. was a most voluminous writer. According to Diogenes Laertius, he left 300 volumes. Among others, he had 37 books on natural philosophy, a treatise on atoms and the vacuum; one on love; one on choice and avoidance; another on the chief good; four essays on lives; one on sight; one on touch; another on images; another on justice and the other virtues, etc. Almost all these works are lost: the only writings of E. that have come down to us are three letters, and a number of detached sentences or sayings, preserved by Diogenes Laertius, in his life of the philosopher. The principal sources of our knowledge of the doctrines of E., besides the above letters, etc., are Cicero, Sen-

æca, and, above all, Lucretius, whose great poem, *De Rerum Natura*, contains substantially the Epicurean philosophy.

Although the majority of E.'s writings referred to *natural* philosophy, yet he was not a *physicist*, properly speaking. He studied nature with a *moral* rather than with a *scientific* design. According to him, the great evil that afflicted men—the incubus on human happiness—was FEAR; fear of the gods and fear of death. To get rid of these two fears, was the ultimate aim of all his speculations on nature.

The following is a brief account of his views. E. regarded the universe (*Tò Pân*) as corporeal, and as infinite in extent, and eternal in duration. He recognized two kinds of existence—that of bodies, and that of *vacuum*, or space, or the intangible nature. Of his bodies, some are compounds, and some atoms or indivisible elements, out of which the compounds are formed. The world, as we now see it, is produced by the collision and whirling together of these atoms. He also held the doctrine of perception by *images* (Gr. *eidôla*), which are incessantly streaming off from the surface of all bodies, and which are necessary to bring us into *rapport* with the world without. In like manner, he believed that sounding bodies threw off emanations, by which we are brought into sympathy with them; and that perception by smell took place in the same way. In psychology, E. was a decided materialist, holding, for various reasons, that the soul is a bodily substance, composed of subtile particles, disseminated through the whole frame, and having a great resemblance to spirit or breath with a mixture of heat.

In seeking to understand the phenomena of the heavens, E. has no scientific end in view; his sole object is to enable the mind to account for them to itself, without the necessity of imagining any supernatural agency at work. "The phenomena of the heavens," says E., "admit of various causes being assigned for their production, equally conformable to the facts learned from the senses. If, then, in thinking of any appearance, we suppose it brought about by the same cause that produces another appearance which gives no alarm or uneasiness, we are as much delivered from uneasiness as if we *saw* that such is the cause of it." E. did not deny that there are gods, but he strenuously maintained, that as "happy and imperishable beings," they could have nothing to do with the affairs of the universe or of men. "Beware," he says, "of attributing the revolutions of the heaven, and eclipses, and the rising and setting of stars, either to the original contrivance or continued regulation of such a being. For business, and cares, and anger, and benevolence, are not accordant with happiness, but arise from weakness, and fear, and dependence on others."

E. next proceeds to deal with the fear of death. Having proved in his psychology that the dissolution of the body involves that of the soul, he argues that the most terrible of all evils, death, is nothing to us, "since *when we are, death is not; and when death is, we are not*. It is nothing, then, to the dead or the living; for to the one class it is not near, and the other class are no longer in existence." Whether E. actually succeeded in removing the terrors of death by his syllogism, may be doubted.

The *positive* part of E.'s system may be noticed in a few words. He held that *pleasure* was the chief good, and it is from a misapprehension of the meaning of this word as used by E. that the term Epicurean came to signify one who indulged his sensual appetites without stint or measure. At the same time, it is easy to see that the use of the word "pleasure" was calculated to produce the mischievous results with which the later Epicureanism was charged. According to E., the sources and tests of all ethical truth are the feelings (*pathe*), and these are two, pleasure and pain. We delight in the one, and avoid the other instinctively. "When we say that pleasure is the end of life, we do not mean the pleasures of the debauchee or the sensualist, as some from ignorance or from malignity represent, but freedom of the body from pain, and of the soul from anxiety. For it is not continuous drinkings and revelings, nor the society of women, nor rare viands, and other luxuries of the table, that constitute a pleasant life, but sober contemplation that searches out the grounds of choice and avoidance, and banishes those chimeras that harass the mind." But, on the other hand, E. says: "If the means to which sensualists owe their pleasures dispelled the anxieties of the mind . . . and enabled them to set limits to their desires, we should have no grounds to blame them for taking their fill of pleasure, wherever they could find it, provided it were attended with no pain or grief from any quarter; for that is the only evil." The whole question of ethics, then, comes to a calculation and balancing of pleasures and pains; in other words, the cardinal virtue is *prudence*. E. rests *justice* on the same prudential basis as temperance. Denying any abstract and eternal right and wrong, he affirms that injustice is an evil, because it exposes the individual to disquietude from other men; justice is a virtue, because it secures him from this disquietude. "Injustice is not an evil in itself, but becomes so from the fear that haunts the injurer of not being able to escape the appointed avengers of such acts." The duties of friendship and good-fellowship are inculcated on the same grounds of security to the individual.

Among the Romans, the system of E. was adopted by many distinguished men. Horace, Atticus, and Pliny the younger were Epicureans; and the splendid poem of Lucretius must have recommended the system to many. In modern times, Epicureanism was resuscitated in France by Pierre Gassendi, who published an account of E.'s life and a defense of his character in 1647. Many eminent Frenchmen have professed his

principles; among others, Molière, Saint Evremond, Count de Grammont, the Duke of Rochefoucauld, Rousseau, Fontenelle, and Voltaire. See Lange's *History of Materialism*, Eng. tr. (1886).

EPICYCLE. The earlier astronomers assumed that all the motions of heavenly bodies took place in circles, the circle being held to be the most *perfect* of all curves; and a necessary consequence of this assumption was, that the motions must have a uniform velocity. Another part of the hypothesis was, that all the heavenly bodies moved round the earth, which remained at rest in the center. The observed phenomena of the heavens, however, were soon seen to stand in glaring inconsistency with these assumptions; and to remedy this, it was necessary to have recourse to additional assumptions. For the sun and moon, which manifestly do not always move with the same velocity, the eccentric circle (q. v.) was imagined. The case of the planets, whose motions were seen to be sometimes direct, sometimes retrograde, and sometimes altogether arrested, offered still greater difficulties; to get over which, the idea of *epicycles* was hit upon. According to this hypothesis, while a planet was moving in a small circle, the center of that small circle was describing a larger circle about the earth. This larger circle was called the *deferent*, and the smaller, which was borne upon it, was called the *epicycle* (Gr. *epi*, upon). In this way the motions of the planets about the earth were conceived to be something like what the motion of the moon about the sun actually is. By assuming proper proportions between the radii of the deferent circle and the E., and between the velocities of the two motions, it was found possible to account pretty satisfactorily for the above mentioned appearances and irregularities in the motions of the planets. But it is only the irregularities arising from the revolution of the earth about the sun that can be at all explained in this way, and not those arising from the elliptic motions of the planets about the sun, nor yet the inequalities of the moon's motions. The successors of the Greek astronomers, down to Tycho Brahé, continued, therefore, to increase the number of epicycles, setting one circle upon another, until the hypothesis, in itself complicated, became still more so, and made the simplicity of the Copernican system at once striking.

EPICYCLOID is the name of a peculiar curve. When a circle moves upon a straight line, any point in its circumference describes a cycloid (q. v.); but if the circle moves on the convex circumference of another circle, every point in the plane of the first circle describes an E.; and if on the concave circumference, a hypocycloid. The circle that moves is the generating circle; the other, the base. The describing point is not necessarily in the circumference of the generating circle, but may be anywhere in a radius or its prolongation. This curve was first investigated by the Danish astronomer Römer. It has many remarkable properties, and is even useful in the practical arts. The teeth of wheels in machinery must have an epicycloidal form, in order to secure uniformity of movement.

EPIDAMNUS. See DURAZZO.

EPIDAUROS, a t. of ancient Greece, on the eastern shore of the Peloponnesus, in the district of Argolis, was situated on a small promontory, 15 stadia in circumference, in the Saronic gulf, in lat. 37° 38' n., long. 23° 10' east. During the most prosperous period of Grecian history, E. was an independent state. It was colonized first, it is supposed, by Carians (hence the older name of *Epicarus*, according to Aristotle), and afterwards by Ionians, but was subsequently invaded by a Dorian army under Deiphontes, the son-in-law of Temenus the Heracleide. This force dethroned Pityreus, the Ionian king of E., compelled him and his citizens to retire to Athens, and inaugurated the Dorian rule, which preserved the ascendancy at E. during the whole of the historical period. The form of government was originally monarchical, but after many vicissitudes, it eventually became and remained oligarchical. At an early period, E. became one of the chief commercial cities of the Peloponnesus. It colonized the islands of Cos, Calyd-nus, and Nisyros, as well as the town of Ægina, which, during the 6th c., attracted all its commerce from the then declining mother-city. E. was chiefly famous for its temple of Æsculapius, to which patients resorted from all parts of the Hellenic world, seeking cures for their diseases. The site of this temple was a plain surrounded by mountains, about 5 m. w. of the town, and which is still called Hieron, the sanctuary. E. had also numerous temples, among which were those of Artemis, Dionysus, Aphrodite, and Hera, and a magnificent theater, at present in a more perfect state of preservation than any in the Peloponnesus, and with sufficient accommodation for 12,000 spectators.

E. (modern Greek, *Epídavro*) is now a small village, with scarcely 100 inhabitants, employed for the most part in raising vegetables for the Athenian market. The plain surrounding the village is productive and highly cultivated. Here, in Jan., 1822, a congress from all parts of Greece assembled, and promulgated the constitution, known as the constitution of Epidaurus.

EPIDEMIC (Gr. *epi*, upon, and *dēmos*, the people), a disease which attacks numbers of persons in one place simultaneously or in succession, and which in addition is observed to travel from place to place, often in the direction of the most frequented lines of communication. Many E. diseases are also contagious, and all of them suggest the necessity of careful inquiry into the ventilation, drainage, food, drink, and habits of the persons liable to be affected. In presence of an E., it is proper to take unusual precautions to

preserve the public health (see article **HEALTH**), and not unfrequently the organization of a regular house-to-house visitation of the locality is calculated to do much good, by directing the minds of the poor and ignorant to their duties in respect to themselves and to each other. See **ENDEMIC** for further observations on this subject; also **CONTAGION**, **INFECTION**, **FEVER**, **CHOLERA**, etc.

EPIDEMIC CEREBRAL MENINGITIS is a disease which has been noticed and described by many American physicians since the year 1811, when Dr. North specially drew the attention of the profession to it. In 1838-40, it appeared in France, and committed great ravages in Versailles, where the mortality was 28 per cent; in Strasburg, where the mortality was 42 per cent; in Lyons, Nancy, and other garrison towns. The patients, in these cases, were almost entirely young conscripts; and the disease was regarded as non-infectious. In the spring of 1846, it appeared in the Dublin and Belfast workhouses, boys under 12 years of age being the only victims, while girls under similar circumstances escaped; it likewise appeared in the constabulary depot, in the same year, amongst the recruits. In 1863, it was very fatal in the United States. In 1865, it ravaged West Prussia: of 2,000 cases recorded, half died; and of 347 cases, 330 were under 14 years of age. In this epidemic, no mention is made of the purple spots which excited such alarm in Ireland; and in the United States, two forms of the disease are recognized—one marked by shock, weak pulse, purpled limbs, and coma, death happening within the first day; the other presenting signs of cerebro-spinal mischief, such as tetanoid spasms, and death here occurring in three days. Purple spots were present in 27 out of 44 cases.

We now pass to the consideration of the so-called *black death*, which, during the two years 1866 and 1867, caused such intense alarm in Ireland, and especially in Dublin. The history of this disease is as follows: A healthy medical student, aged 19, residing in Dublin, fell ill with chilliness and *malaise* about noon on Mar. 18, 1866. When he was visited in the evening, it was found that he had vomited frequently and was very prostrate; purple blotches appeared on his skin during the night, and about noon next day, he suddenly fell into stupor, and was dead at two, or about 26 hours from the apparent commencement of the symptoms. Drs. Stokes and Benson, who, with Mr. Croly, saw the case, at once recognized it as presenting a novel type of disease. A girl, aged 18, presented similar symptoms on April 2, but recovered. Fatal cases were recorded on May 12, 13, and 17. According to Dr. Mapother—from whose excellent report “On the malignant purple fever epidemic in Ireland,” read before the epidemiological society in July, 1867, the materials of this article are almost entirely drawn—it appears that 63 fatal cases had been registered (up to July) in the Dublin district, exclusive of eight deaths amongst soldiers. This able physician gives the following description of the symptoms, which include two types of very different severity, and in this respect he agrees with the American observers. In the graver, life is rapidly extinguished as if by a blood-poison; in the milder, the symptoms are those of inflammation of the cerebro-spinal axis, or its membranes. Dr. Stokes, however, regards these latter phenomena as secondary to the essential disease, and believes that they will always appear, if the patient lives long enough for their development. The earliest symptoms are chilliness and a sense of impending danger, and vomiting of a persistent character soon follows. There is constipation till shortly before death, when the evacuations are involuntarily discharged. The tongue is dry; the pulse abnormally compressible, and usually over 100. The dark purple blotches, caused by the escape of dissolved hematine (coloring matter of the blood) from the smaller vessels, are situated in and under the true skin of the legs, hands, face, back, and neck. These patches vary in size from that of a pin's head to that of a walnut, and are often sufficiently raised to be detected by the touch. The skin is dusky and moist, sometimes even bathed in sweat. In some cases, stupor, and in others, delirium and intense restlessness, are the forerunners of death. The rapidity with which this disease runs its course is appalling. A healthy boy, aged 10½ years, sank in less than 5 hours from the time of his seizure; and of 41 investigated fatal cases, 14 terminated within 24 hours. Of these cases, 21 were females, and 20 males. Youth predisposes very strongly to the disease. No position in life affords exemption; one young nobleman, three medical students, two undergraduates, and several inhabitants of the lowest hovels—the seats of typhus and cholera—were amongst the victims.

With regard to treatment, almost every kind has been tried, and each has been found equally unavailing. The external application of cold to the spine and head, as advocated in various forms of disease by Dr. Chapman, deserves a trial. Dr. Mapother suggests that the disease is due, like scurvy, to the want of fresh vegetables as an article of food; and if this view is correct, it is satisfactory to feel that if this terrible malady is incurable, it is at all events preventable. A few cases of this disease have been recorded as occurring quite recently in various parts of England. They would probably have passed unnoticed but for the Dublin epidemic. See **MENINGITIS**.

EPIDEMIC MENTAL DISEASES. When we consider how ordinary and normal thoughts and emotions spread from one man to many, and sway multitudes to the same views and actions, it is no longer a mystery that morbid conditions of the mind should become at times no less epidemic than physical diseases. Such, at least, is the fact. A

mental disorder may spread from man to man, and may involve whole nations. It depends for its propagation, like an epidemic disease, first upon external circumstances, and secondly, upon the peculiar condition or constitution of the individuals affected. Like the bodily affection, the causes which provoke the insanity and the tendency to be affected may have been in process of development for years. Both attack the weak rather than the strong; both exist for a season, and disappear. In the case of the mental malady, the external influences—those which constitute the moral atmosphere—are ignorance or imperfect knowledge, the power of one mind over another, the influence of language, the diffusion of particular opinions, the tendency to imitate. It is probable, however, that physical causes exercise an important influence in the production of such general mental conditions. In 1842 and 1844, there occurred in Germany and France, among the military, epidemics of meningitis with delirium, or inflammation of the membranes of the brain, when no moral factors were at work, but when diet, temperature, etc., were. But even where the origin cannot be so distinctly traced, the co-operation of external as well as psychical agents may be legitimately predicated. It would accordingly be illogical to limit the production of the dancing mania (q. v.), which occasionally, during several centuries, swept over Europe, to the reaction succeeding the dread of the end of the world, which had previously prevailed epidemically. An examination of about a hundred manifestations such as that alluded to, collected from various sources, demonstrates that not merely the intoxication of joy, but the most absurd forms of belief—that dreams, delusions, superstitions, corruptions of language, all instincts and passions, even movements and cries, may assume the forms, and, to a certain extent, may follow the laws of epidemic diseases. In far-distant ages, there are records of a histrionic plague, when, after a summer of intense heat, all conceived themselves players, and traversed the streets, and sunk and died, repeating verses, and exhibiting extravagant gesticulations; of whole communities being stricken with nightmare, which was so general as to be supposed and called contagious. There have been epidemics of homicidal and suicidal mania. In one age, hundreds are found possessed by Satan; in another, larger numbers converted into wolves; and in recent times, the leaping ague of Forfarshire, and outbursts of pyromania in various places, remind us that there may be still in the constitution of the human mind, and in the education and the habits of life prevailing, elements capable of realizing the catastrophe suggested by bishop Butler's question: What is to prevent a whole nation becoming mad? The instances of epidemic mental disease recorded in the following table, have been selected from a vast number of others, with a view of showing not the frequency or extent of such affection, but the range of the phenomenon through the powers and propensities of our nature.

| Popular Name. | Form of Disease. | Year. | Number Affected. | Authority. |

There appears to be no guarantee that the present and future generation shall be exempted from similar visitations, except in the universal diffusion of knowledge and sound thinking, for it is invariably in the darkness of ignorance or in the twilight of imperfect knowledge that the moral plague comes.—Hecker's *Epidemics of the Middle Ages*; Calmiel, *De la Folie considérée sous le Point de Vue Pathologique, Philosophique, Historique et Judiciaire, depuis la Renaissance des Sciences en Europe jusqu'au dix-neuvième Siècle*, etc.; and *Psychological Journal*, *passim*.

EPIDENDRUM, a genus of epiphytic orchids, of which there are 7 examples in the United States, some growing upon magnolia trees. The blossoms are greenish-purple, growing in large clusters. Some of the many species in the tropics are very showy, and some have cathartic qualities.

EPIDERMIS (Gr. *epi*, upon, and *derma*, the skin), a semi-transparent membrane, containing neither vessels nor nerves, and everywhere forming an external covering to the corium or true skin. See **SKIN**. The E. is called in ordinary language the *scarf-skin*. It consists of two layers, chemically and morphologically distinct—viz., the *mucous layer*, which lies immediately upon the corium, and the *horny layer*, which forms the outermost surface of the body.

The *mucous layer* (known formerly as the *rete mucosum s. malpighianum*) is of a whitish or slightly brown tint (in the negro, dark gray or black), and is composed of small soft cells. The innermost of these cells, resting on the surface of the corium, are elongated and arranged perpendicularly; upon these follow elongated or roundish cells in many layers, which, in proportion to their distance from the corium, acquire, from

their mutual pressure, a polygonal form, which may even be recognized in individual cells.

All the cells in the mucous layer are nucleated vesicles distended with fluid, and likewise containing minute granules, which diminish in number in the more external cells.

The *horny layer* forms the external semi-transparent part of the E., which in the white races is colorless, and is composed almost wholly of uniform cells, metamorphosed into plates or scales. The deepest plates in some degree resemble the uppermost cells of the mucous layer; but in the second or third layer we find the flattening commence; till at length, after a gradual series of modifications, we have the hard, horny scales which occur on the surface, where they are regularly cast off with more or less rapidity, and replaced by those beneath them.*

The color of the E. differs in different persons and in different parts of the body. It is deepest around the nipple, especially in women during pregnancy and after they have borne children. A more or less dark pigment is often deposited, in persons who are exposed to the sun, in the face, neck, back of the hands, etc. These tints are not produced by special pigment-cells, but are seated in the common cells of the mucous layer, round whose nuclei granular pigment is deposited. In the negro and the other colored races, it is also only the E. which is colored, while the *corium* completely resembles that of Europeans. The perpendicular cells are the darkest, and form a sharply marked fringe at the edge of the clear corium. To these succeed brown cells, which accumulate in the depressions between the papillæ, and as we approach the horny layer, we have yellowish cells. The horny layer of the negro also inclines to a yellow or brownish tint.

Morbid coloration of the E. (freckles, mother's marks, etc.) is produced in the same way as the color of the negro's skin. Numerous instances of partially or entirely white negroes and of black Europeans, not as a consequence of change of climate but as an abnormal condition of the skin, are on record.

The thickness of the E. varies extremely. While upon the cheeks, brow, and eyelids, it varies from $\frac{1}{4}$ th to $\frac{1}{5}$ th of a line, on the palm of the hand it ranges from $\frac{1}{4}$ d to $\frac{1}{2}$ a line, and on the sole of the foot sometimes even exceeds a line. In some parts of the body the horny layer is thicker than the mucous; in other, the mucous is the thicker of the two. As the chief use of the E. is that of affording protection to the soft and tender subjacent parts, it attains its greatest thickness on those portions of the body (the palm of the hand and the sole of the foot) which are most exposed to pressure and friction.

In *plants*, as in animals, the E. is formed of flattened cells, of which also new layers are continually produced from the bark below, whilst the outer ones dry up, lose their vitality, and peel off, crack and split off, or otherwise become separated from the living organism. The cells of the E. are often enlarged outwards, so as to form projections, sometimes very slight, sometimes elongated into hairs (q.v.). Glands are also connected with the E., sometimes by the intervention of hairs, sometimes without, and in this way it contributes to the secretion of substances formed in plants by the wonderful chemistry of nature, and on which their value to man often greatly depends. The cells of the E. are usually filled with a colorless fluid, but resinous and waxy substances are sometimes found in them, and sometimes silica (as in grasses and equisetaceæ), sometimes carbonate of lime (as in the *charas*). The epidermis is pierced by *stomata* (q.v.). When the E. of plants is subjected to prolonged maceration, it can often be made to separate into two parts; one, which is more strictly called the E., being the inner, lower, and thicker membrane; the other, which is called the *pellicle* or *cuticle*, being very thin, and extending continuously over every part of the plant except where it is pierced by the stomata. Thus, this superficial pellicle invests even the finest hairs. In some of the *algæ*, it seems to constitute the whole integument. In the greater number of plants, the E. is thin and soft, but sometimes it is thick, and sometimes hard.

EPIDOTE, a mineral allied to garnet, composed of silica and alumina, with a considerable proportion of lime, or of peroxide of iron, or of peroxide of manganese. These diversities of composition constitute three very distinct varieties; and of these there are sub-varieties, differing in color and other particulars (*pistacite*, *bucklandite*, *withamite*, *zoisite*, etc.). E. is sometimes found massive, foliated, columnar, granular, or incrusting; often crystallized. Its crystals are prisms, variously modified. Its prevalent colors are green, yellow, and gray, but some of the varieties are red and black. It is found in gneiss, syenite, trap, and other rocks in a number of localities in Scotland, and in many parts of the world.

EPIGÆA REPENS. See ARBUTUS, TRAILING.

EPIGASTRIUM (Gr. *epi*, over, and *gastēr*, the stomach), the part of the abdomen (q.v.) which chiefly corresponds to the situation of the stomach, extending from the

* In reptiles and amphibians, this layer is periodically cast off in a more or less entire state, a new one being previously formed beneath it; and in man, desquamation in large patches often occurs after certain diseases, especially scarlatina.

sternum towards the navel or umbilicus (q.v.), and bounded on each side by the hypo-chonders (q.v.). It is called in popular language the pit of the stomach.

EPIGENESIS (Gr. *epi*, upon, and *genesis*, a formation), a formation upon, or in addition to, previously existing parts. The word is applied in physiology to that theory of new formations in organized beings which supposes them to spring from superadded centers of vital activity, as opposed to the theory which presumes that the new is formed by a development or modification of the old structure. See REPRODUCTION.

EPIGLOTTIS. See LARYNX.

EPIGONI, in general, sons of descendants, applied more particularly to certain mythical chiefs who fought against Thebes. After the catastrophe which brought about the death of Jocasta and the blinding of Œdipus, Eteocles, and Polynices, the sons of Œdipus and Jocasta incurred the wrath of their father, whom they sent forth alone and blind to fight with poverty. The father's curse rested on them, and resulted in the famous "war of the seven against Thebes." All the chiefs who led the war were slain except Adrastus. A second war was undertaken by the children of the fallen chiefs, and this is known as the "war of the Epigoni." The Epigoni were victorious, and Thebes was taken, Thersandrus, the son of Polynices, being seated on the throne of Cadmus. In literary history, the term E. is sometimes applied to a scholar who limits himself to unfolding the ideas of the great masters of a previous age.

EPIGRAM, a word derived from the Greek, and literally signifying an "inscription." In point of fact, the epigrams of the Greeks were simply inscriptions on tombs, statues, and monuments, written in verse, and marked by great simplicity of style, but having nothing in common with what now passes under the name. It was among the Romans that the epigram first assumed a satirical character. Catullus and Martial are reckoned the best Latin epigrammatists. In modern times, an epigram is understood to be a very short poem, generally from two to eight lines, containing a witty or ingenious thought expressed in pointed phraseology, and in general reserving the essence of the wit to the close, as the serpent is fabled to keep its sting in its tail. The French excel all other nations in this kind of poetry. Their earliest epigrammatist of any note was Clement Marot (1495-1544); their best are Boileau, Voltaire, and Piron. The epigrams of German writers are for the most part happily expressed moral proverbs, but the *Xenien* of Schiller and Goethe contain not a few sharp and biting verses of a satirical character. In English, Pope, Burns, Byron, Moore, and other writers have shown a remarkable power of epigrammatic satire. See Booth, *Epigrams, Ancient and Modern* (1863).

EPIGRAPH (Gr. *epi*, upon, and *grapho*, I write), a terse inscription placed upon architectural or other monuments, for the purpose of denoting their use or appropriation.

EPIGRAPHY. See INSCRIPTIONS.

EPILEPSY (Gr. *epi*, upon, and *lambanō*, future, *lēpsō*, I seize), a form of disease characterized by sudden insensibility, with convulsive movements of the voluntary muscles, and occasionally arrest of the breathing, owing to spasm of the muscles of respiration, and temporary closure of the glottis (see LARYNX). E. was called by the ancient Greeks the "sacred disease." Owing to the mysterious and extraordinary character of the convulsion of E., it was always, in ancient times, supposed to be due in a very special manner to the influence of the gods, or of evil spirits; Hippocrates, however, combats this idea in a special treatise, in which he maintains that E. is no more and no less divine than all other diseases. The same idea of the specially supernatural character of E. is shown forth in the deeply rooted oriental notion of demoniac possession. See DEMONIACS. E. is often called, in modern language, the "falling sickness," and this name is not only descriptive of one of its most striking phenomena, but also points distinctly to the most obvious danger of the fit. The patient is seized, without reference to his condition or occupation at the moment, with insensibility, often so complete and sudden as to lead to serious accidents and bodily injuries; in the most aggravated cases, he has no premonitory sensations whatever, but falls down without any attempt to save himself, and usually with a wild inarticulate cry of some kind, immediately after which the face is violently distorted, the head drawn towards one or other shoulder, and the whole body convulsed. These convulsions follow in rapid succession for a few minutes, and are attended by foaming at the mouth, and by great lividity, or, in some cases, livid pallor, which, with the irregular spasmodic movements of the lips, nostrils, and eyes, give a frightfully ghastly expression to the countenance, and almost invariably lead the bystanders to an exaggerated idea of the immediate danger of the fit. The immediate danger is, in reality, not great, excepting that the sudden attack may lead to an injurious or fatal fall; the tongue, however, may be bitten if protruded during the convulsion, or the patient may be so placed as to injure himself seriously by the repeated and unconscious movements of his body, or he may suffocate himself by accidentally falling with his face in water, or otherwise closing up the mouth and nostrils, or by dragging upon a tightened neckcloth. Care should be always taken to avoid these accidents by keeping the epileptic as much as possible within view of persons acquainted with his condition, and able to give such assistance as may be required; as well as by warning the patient himself to avoid all places in which a fall would be especially dangerous. But when an unskilled person happens to witness a fit of E.,

he will do well to remember that beyond the simplest and most obvious precautions against the dangers mentioned above, there is literally nothing to be done; and any attempt to rouse the patient by violent stimuli, as ammonia applied to the nostrils, or by dashing water in the face, or, still more, by administering medicines hastily recommended by the ignorant and thoughtless, is almost certain to do more harm than good. The tongue should be looked to, a piece of cork or other gag being, if necessary, inserted between the teeth; the patient should be then placed on a mattress or other soft place near the ground; his neckcloth should be removed, and the dress loosened round the chest; the head should be, if possible, a little raised, and a free circulation of air maintained (this last precaution being very apt to be neglected in case of a crowd); with these things done, it may be safely affirmed that in the vast majority of epileptic cases nothing has been left undone which will conduce to recovery. The ordinary course of the fit (which usually lasts from five to twenty minutes altogether) is as follows: the convulsions gradually diminish in intensity, and the patient passes into a state of deep but motionless stupor, with dilated pupils, and sometimes, but not always, with snoring or noisy breathing; the foaming at the mouth ceases, the color gradually returns, and this state leads to recovery through a more or less protracted, but apparently natural sleep, the patient, on awaking, being often quite unconscious that he has been the subject of any anxiety, or, indeed, in any unusual condition whatever. Although in all cases of true E. there is a stage of complete coma (q.v.), or unconsciousness, yet the fit is often very transient, and but little attended by convulsion, being also less sudden than above described, and not necessarily causing a fall to the ground; in some cases, also, fits of greater intensity are preceded by certain premonitory symptoms or peculiar sensations, which act as warnings to the patient himself, and lead him to place himself in a position of safety on the approach of the paroxysm. Having in view these distinctions (which are certainly of considerable practical importance), the French language, both popular and scientific, has adopted the terms of *grand mal* and *petit mal* (i.e., great and little evil), as characterizing the more and less dangerous forms of E. respectively. The sensations which precede the fit in some epileptics have been termed in Latin the *aura* (i.e., breath) *epileptica*, from their supposed resemblance to a current of cold air passing over the body, and proceeding from the extremities towards the head. This description does not, however, hold good in all cases; and not unfrequently, as mentioned above, there is no *aura*, or unusual sensation of any kind, preceding the fit. It must be mentioned, however, as bearing on treatment, and as being quite within the bounds of popular medicine, that some of the most ancient authorities assert strongly the power of a tight bandage, placed suddenly upon the limb in which the *aura* begins, to cut short, or even to prevent altogether, the fit of epilepsy. Although this alleged fact has often been regarded as doubtful, it has never been altogether discredited, and has of late years been brought into renewed notice by good observers. It is even maintained that such a bandage, placed experimentally upon one or other of the limbs, and tightened on the approach of a fit, has been found effective in some cases in which there was no distinctly local sensation; and epileptics have been repeatedly convinced of the propriety of habitually wearing a bandage loosely applied upon the arm, which they have been able, by carefully watching their own sensations, and by being watched in turn by others, to get tightened at the proper time. There is no doubt room for fallacy in these observations, but they may safely be commended to notice, as involving no possible risk of mischief, and as far more worthy of extended trial than the great majority of popular remedies in epilepsy.

But the fit and its treatment form only a part of the anxieties which arise out of a case of epilepsy. The ultimate danger of the disease has little relation to the severity of the individual fits, except in the modified sense explained above; the frequency of the attacks being apparently much more apt to influence the duration of life than their character. Indeed, although epileptics may survive several severe paroxysms at distant intervals, and recover in the end with an apparently unbroken constitution, it rarely happens that very frequently repeated attacks, even of the *petit mal*, are unattended by some permanent depreciation of the powers of mind or of body. The most frequent, perhaps, of all the more serious consequences of confirmed E. is insanity (q.v.), sometimes assuming the form of acute mania or monomania following the attacks, but quite as frequently tending to gradual imbecility without any acute seizure. Sometimes the development of the epileptic insanity, or dementia, is attended by palsy, and other indications of structural disorder of the brain; in other instances, no such consequences occur, and the brain after death may be found to have very little tangible disease, or only such disease as is found in numerous other cases of functional derangement. Very often, even when the mind remains tolerably entire, there is loss of memory, and a certain want of acuteness and depression of spirits, which unfit the individual for the regular business of life. Disorders of the digestion are also not uncommon; and there is frequently a want of tone and vigor in all the bodily functions, which communicates a habitual expression of languor and reserve to the epileptic. Added to this, it can hardly be matter of surprise that the knowledge of his infirmity should deeply influence the mind of the epileptic, and produce a distaste for active occupations, especially for such as expose him to more than ordinary observation.

The causes and the radical cure of epilepsy are almost equally involved in mystery.

It has been supposed by some to be dependent on an increased afflux of blood to the brain; while by other observers and pathological authorities it has been attributed, with about equal force of reasoning, to precisely the opposite condition. Certain cases undoubtedly depend upon organic disease, as tumors or injuries to the brain and its membranes, more especially near the surface. Local sources of irritation in other parts of the body have also been supposed to be exciting causes of E.; and cases are recorded in which the disease has been cured by the amputation of a finger or the division of a nerve. The attention of recent observers has been especially directed to the medulla oblongata and spinal cord (q.v.), as being the most probable physiological seats of a disease so decidedly marked by convulsive movements. But as yet little more than the most vague theoretical inferences can be drawn from their researches as to the cause either of the morbid tendency in E. or of the paroxysm. One of the most curious and suggestive of these recent facts is the experiment of Brown-Sequard, showing that E., or a state closely resembling it, may be induced in certain animals by division of certain portions of the spinal cord, the artificial disease continuing long after the primary effects of the injury have ceased. A still more curious and inexplicable phenomenon has resulted from the multiplication of such experiments; for Brown-Sequard has shown that in guinea-pigs this artificial E. is sometimes propagated to the offspring, becoming, like the natural disease, a hereditary and congenital morbid tendency. On these strange facts it would be premature to indulge in speculation in this place, but their great importance can hardly be overlooked.

The condition of the epileptic seems to be favorably affected by everything which conduces to a quiet and hopeful state of the mind, and to a vigorous condition of the body. The treatment of the disease should therefore, in general terms, be of the kind termed *tonic* (q.v.), and should be adapted with care, and after very minute and careful inquiry, to the removal of all the special bad habits, and occasional causes of depression, which tend to bring the system into a condition *below par*, in the individual case. The influence of a happy and quiet domestic life, without unhealthy excitement, and with proper occupations, varied by amusement and exercise in the open air, can hardly be overestimated. The marriage of epileptics is, however, not too readily to be sanctioned, as it has been known to be followed, not only by an increase of the disease, but by its transmission to a considerable portion of the family. On the other hand, a too absolute rule on this subject is not without its dangers, and perhaps the practical difficulties of the question are not to be met by any defined or dogmatic expression of opinion, founded on the general pathology of the disease. If the tendency exist, even slightly developed, upon both sides in such a connection, it needs hardly be stated that the dangers of transmission to the descendants is increased in a very great degree. Hence, intermarriages *within epileptic families* must be regarded as always in the highest degree imprudent. Parents and guardians are undoubtedly justified in making this disease an object of special solicitude, and reserve or concealment on this subject on either side, in the case of a proposed marriage, should be regarded as equally dishonorable with any other form of deception in a matter so important to the welfare of society and of the parties concerned.

According to one of the ablest and most respected of American physicians (Dr. Jackson, of Boston), the epileptic tendency may often be successfully treated by the systematic use of an exclusively vegetable diet, or by a very considerable reduction of the proportion of animal food. Among the innumerable remedies recommended by authorities, the salts of iron and zinc have perhaps the largest amount of experience in their favor; and counter-irritants (q.v.) applied to the nape of the neck, or between the shoulders, either by blistering, the use of the seton, or even actual cautery, has been often followed by prolongation of the intervals, or decrease in the severity of the fits. Almost all the accredited remedies, however, have been observed to produce a temporary relief of this kind, even when without any permanent influence on the course of the disease.

Some of the *lower animals* are subject to epileptic fits. The disease is common in dogs and highly-bred pigs. The creatures writhe with involuntary spasms, and are for the time without sight or hearing. Sometimes the muscles of the throat are so involved that fatal suffocation occurs. The attack is generally preceded by dullness, and lasts from ten to thirty minutes. It is generally traceable to torpidity or irregularity of the bowels, worms, debility, or plethora. In dogs, it is a frequent sequel of distemper. In cattle, it usually occurs in connection with the engorgement of the first or third stomachs; they throw themselves violently about, bellowing loudly, but seldom die. It is rare in horses, and differs from megrims, for which it is often mistaken, but in which there are no spasms. The treatment consists in freely opening the bowels, removing worms, if any are present, enjoining bleeding and spare diet, if the patient's condition is high, and generous feeding and tonics where it is low. The best preventives are carefully regulated diet, an occasional laxative, with a course of tonics, and especially of arsenic.

EPILOBIUM, a genus of plants of the natural order *onagraceæ*, having four deciduous calycine segments; four petals; a much elongated, 4-sided, 4-celled, 4-valved, many-seeded capsule; and seeds tufted with hairs at one end. The species are herbaceous

perennials, natives of temperate and cold countries, and very widely diffused both in the northern and in the southern hemisphere. Some of them are very ornamental, from the beauty of their flowers. Most of the British species have small flowers, and some of them are very common in moist places. *E. angustifolium*, which differs from all the other British species in having the petals dissimilar in shape and size, is frequently planted in gardens and shrubberies, on account of its numerous and beautiful rose-colored flowers; but its creeping roots are apt to overrun a flower-garden. It is sometimes called FRENCH WILLOW, from the resemblance of its stems and leaves to some kinds of willow, and the name WILLOW-HERB is often extended to the whole genus. It is found in very northern regions, and its leaves and young shoots are sometimes a grateful addition to the meals of the arctic traveler, although not likely to be relished in almost any other circumstances. The pith, when dried, yields a quantity of sugar to boiling water, and is used in Kamtchatka for making a kind of ale, from which also vinegar is made.

EPILOGUE (Gr. *epi*, upon or after, and *logos*, a speech) means, in oratory, the summing up or conclusion of a discourse; but, in connection with the drama, it denotes the short speech in prose or verse which frequently, in former times, was subjoined to plays, especially to comedies. The E. was always merry and familiar in its tone, and was intended to establish a kindly understanding between the actor and the audience, as well as to conciliate the latter for the faults of the play, if there were any, and to send them away in good humor. One of the neatest and prettiest epilogues ever written, and one which completely realizes what an E. should be, is that spoken by Rosalind at the conclusion of Shakespeare's *As You Like It*.

EPIMACHUS, a genus of birds of Australia and Papua, not unlike the bird of paradise; in color, violet black or black brown, with a collar of feathers margined with green at the base of the neck. The tail feathers consist of about 12 long plumes ending in thread-like points. The head and breast are brilliant blue.

EPIMENIDES, a Greek poet and priest, b. probably at Phæstus in Crete, in the 6th or 7th c. B.C., and lived at Cnossus. His history has only reached us in a mythical form. He is said to have fallen asleep in a cave when a boy, and not to have awakened for 57 years. Like Rip Van Winkle, he was naturally much astonished and perplexed on his return to broad daylight. His period of slumber, however, had not passed away unprofitably. His soul, disengaging itself from its fleshly prison, betook itself in the interval to the study of medicine and natural philosophy; and when it had shuffled on again its mortal coil, E. found himself a man of great knowledge and wisdom. Goethe has written a poem on the subject, *Des Epimenides Erwachen*. E. went to Athens about 596 B.C., where, by the performance of various mystical rites and sacrifices, he stayed a plague with which the inhabitants were afflicted. When he died is not known, but we may be certain that he did not live (as is fabled) for 299 years. That he wrote the epic poems attributed to him, the longest of which was on the Argonautic expedition, is considered highly improbable. Compare Heinrich, *E. aus Kreta* (1801).

EPINAL, a t. of France, in the department of Vosges, is situated in a delightful district at the western base of the Vosges mountains, on both banks of the Moselle, about 200 m. e.s.e. of Paris. Lat. 48° 10' n., long. 6° 26' east. It is a well-built, handsome town, with clean and regular streets, and is surmounted by the ruins of an old castle, the gardens attached to which are much admired. Among its chief buildings are the parish church, an antique Gothic structure; the hospital, formerly a Capuchin convent; a museum of pictures, antiquities, and natural history; the barracks; and the residence of the prefect of the department. E. has a variety of manufactures, including cotton fabrics, wrought-iron, pottery, cutlery, paper, and leather, and has some trade in grain, wine, timber, etc. Pop. '91, 21,431.

ÉPINAY, LOUISE FLORENCE PÉTRONILLE DE LA LIVE D', a French writer, b. March 11, 1726. At the age of 19, she married her cousin, M. d'Épinay, but the union did not prove a happy one. While her husband was abandoning himself to dissolute courses, she sought the intercourse of philosophers and men of genius. In 1745 she formed a close intimacy with Rousseau, and presented him with a small house (the now famous Hermitage) which stood on one of her husband's estates in the woods of Montmorency. An unfortunate jealousy, however, which Rousseau conceived for Grimm, another friend of Mme. d'É., was followed by an open rupture with his benefactress, and in his *Confessions* he scrupled not to malign her by way of vengeance. She spent the remaining 25 years of her life in comparative solitude, seeing only a small and select circle of philosophers and littérateurs. When Grimm was obliged to leave Paris, she continued, under the direction of Diderot, his literary correspondence with northern sovereigns. She died in 1783. From the pen of Mme. d'É. we have *Conversations d'Émile* (Paris, 1774), a work on education pronounced by the French academy to be the most useful that had been published for a number of years; *Mémoires et Correspondance de Madame d'Épinay renfermant un Grand Nombre de Lettres inédites de Grimm, de Diderot, et de J. J. Rousseau, etc.* (Paris, 1818); *Les Confessions du Comte de ****; etc.

EPIPHANIUS, SAINT, a Christian bishop, and writer, was b. of Jewish parents in Palestine about 315 A.D. He was baptized in his 16th year, and was educated among the Egyptian monks, who inspired him with an aversion to all liberal science. He rose

gradually to the rank of bishop of Constantia (formerly Salamis) in Cyprus, and continued in that office from 367 till his death in 403. His polemical zeal was conspicuously manifested against Origen. He had proclaimed him a heretic in his writings, and in 394 he went to Palestine, the focus of Origen's adherents, and called upon John, bishop of Jerusalem, and the two monks, Rufinus and Jerome, to condemn him. A more legitimate object of his violent opposition was the increasing worship of images. Jerome relates how he indignantly tore down an image in the precincts of a church in Palestine, as being contrary to the divine law. Among his writings, collected by Petavius (2 vols., Paris, 1632), the most important is his *Punarión*, or catalogue of all heresies (80 in number), a work which strikingly shows his unfitness for being a historian. His credulity and want of honesty are excessive.

EPIPH'ANY (Gr. *Epipháneia*, appearance), denoted, among the heathen Greeks, a festival held in commemoration of the appearance of a god in any particular place. The word subsequently passed into the usage of the Christian church, and was used to designate the manifestation or appearance of Christ upon the earth to the Gentiles, with especial reference to the day on which he was seen and worshiped by the wise men who came from the east. This occasion is commemorated in the church on the 6th of Jan., the 12th day after Christmas, and hence the E. is also called twelfth day. The E., which is said not to have been observed as a separate festival, but to have been included in the feast of the nativity till 813, is observed as a "scarlet day" at Oxford and Cambridge.

EPIPHE'GUS, a parasitic herb growing from the roots of the beech tree, and seeming to grow from the ground independently. It is 6 to 12 in. high, purple or yellow-brown, slender, with scales instead of leaves. In Virginia it is called "cancer-root," and has the reputation of being a specific for that disease.

EPI'PHYTES (Gr. *epi*, upon, *phyton*, a plant), often and popularly, but less correctly, called air-plants, are plants which are not rooted in the ground, but are attached to trees, from the decaying portions of the bark of which, or of mosses and lichens which grow upon it, they derive their nutriment, probably, also, depending upon the air for it to a larger extent than other plants do. Mosses and lichens, themselves, growing upon trees, may be called E., but the term is generally used of phanerogamous plants. E. are not connected with the trees upon which they grow in the peculiar manner of the mistletoe, *balanophora*, and other true parasites—not sending roots like them into the wood to suck the juice of the tree. It is chiefly in warm climates that phanerogamous E. are found and in those which are also moist. Most of them prefer shady situations. Within the tropics, they often form an interesting and remarkable feature of the vegetation. Some of the *bromeliaceæ* (as *tillandsia*), *cactaceæ*, *araceæ*, *gesneraceæ*, and other natural orders are E.; but the order to which they belong more than to any other is *orchidaceæ*. Many of the epiphytous orchids, as well as other E., are remarkable for their beauty; and the attention which has recently been given to their cultivation in hothouses has been rewarded by the most perfect success. See ORCHIDS. Plants which usually occur as E. are sometimes also found growing on rocks. Although seldom found except in moist climates, E. are generally capable of enduring a considerable amount of drought, parding slowly with the moisture which they have once imbibed.

EPI'RUS, the ancient name of a part of Greece, bounded on the e. by the chain of Pindus, on the s. by the Ambracian gulf, on the w. by the Ionian sea, and on the n. by Illyria and Macedonia. It formed the southern part of modern Albania, or the pashalic of Janina, a wild and mountainous region, the haunt of robbers and semi-civilized tribes in all ages. The chief town was Dodona (q.v.); the chief rivers, the Acheron, Cocytus, Arachthus, and Charadrus. Anciently, it was celebrated for its cattle and its breed of Molossian dogs. Its earliest inhabitants were probably Pelasgians. In the historic period, Theopompus speaks of fourteen tribes, most of whom were believed by the Greeks themselves to be not of Hellenic origin. The principal were the Chaones, Threspoti, and Molossi, the last of whom finally obtained the entire sovereignty of the country. Of the Molossian kings of E., the most distinguished was Pyrrhus, who long waged successful war against the Romans. But after this race of kings became extinct (239-229 B.C.) by the death of Ptolemy, grandson of Pyrrhus, a republican constitution was adopted, whereupon parties sprang up among them, and the neighboring Macedonians got the upper hand. On the conquest of Macedonia by the Romans (168 B.C.), the Epirots were accused of having assisted Perseus, the Macedonian king, and the most revengeful measures were put in force against them. Æmilius Paulus, the Roman gen., plundered and razed to the ground the 70 towns of E., and sold into slavery 150,000 of the inhabitants. From this period, E. shared the vicissitudes of the Roman and Byzantine empires, until 1204, when one of the Comneni made himself independent. His dynasty ruled the country until 1466, when it was finally conquered by the Turks (see SCANDERBEG). E., peopled largely since the 14th c. by Albanians (see ALBANIA), formed latterly a part of the Turkish vilayet of Janina. The Berlin congress of 1878 recommended that the southern part of E. should be ceded to Greece. The district e. of the river Arta was ceded, 1881.

EPIS'COPACY (Gr. *episcopos*, bishop or overseer) is that form of church government in which one order of the clergy is superior to another—namely, bishops or prelates to

priests or presbyters, the ordinary ministers of parishes or congregations. It is sometimes called *diocesan episcopacy*, to distinguish it from that *episcopacy* which Presbyterians and Independents also assert—the oversight of flocks by their pastors. See BISHOP. It is not essential to E. that there should be *archbishops*, exalted in rank and authority above other bishops, although of the same order: and in some Episcopalian churches there are none.

E. has actually subsisted under very various modifications; the power of bishops being more or less absolute, or more or less controlled by synods of presbyters, or even—in the Protestant Episcopal church of the United States—by a diocesan convention, composed both of presbyters and lay delegates. The power of the bishop is also variously affected by the relations subsisting between church and state; and great differences exist in this respect between the church of England, the church of Sweden, and the church of Denmark, all Episcopalian, and all connected with the state as *established churches*.

The church of Rome, the Greek church, and other branches of the eastern church, are Episcopalian. Of Episcopalian Protestant churches not established, the most important are that in the United States, that in Scotland, and the Moravian church. See ANGLO-CATHOLIC CHURCH; and ENGLAND, CHURCH OF. After a great deal of learned discussion standard writers on both sides of the question now admit that the term “*episcopos*,” when it appears as a term of office in the New Testament, is synonymous with “*presbyter*,” the same officers of the church being called by both names—the one with reference to their duties, and the other to their age. The “*presbyters*” or elders of the Ephesian church were called by Paul “*bishops*” or overseers of the flock. In the pastoral epistles, both words are used interchangeably. Peter, exhorting the “*presbyters*” as their brother “*presbyter*,” speaks of their office as that of an overseer or “*bishop*.” 2. In each church of the New Testament there seems to have been, at first, a plurality of presbyters or bishops. In the church of Ephesus (as has just been said), there were presbyters who were bishops. In the church at Philippi, there were bishops as well as deacons. Paul and Barnabas, in their journey, ordained presbyters in every church. 3. In each church, it may be taken for granted that some one of the officers was chosen to preside. This choice, the advocates of prelacy affirm, was made at first by apostolic authority or in imitation of apostolic example. Presbyterian and Congregational writers, on the other hand, regard it as only a wise human arrangement similar to that which convenience and order suggest in all associations of men. 4. Gradually the two synonymous names of office were divided; “*bishop*” being restricted to the president, and “*presbyters*” continued to the rest. This division, the prelatical theory of church government asserts, was made by apostolic agency in the accomplishment of a divine intention that the bishop, as a successor of the apostles, should be vested with authority over the presbyters and the church. The non-prelatical theory, on the contrary, affirming that the apostles, as such, had no successors, maintains that the division of title and of function was made without apostolic agency and contrary to the spirit of the Savior’s command; that it was a result of the innate tendency in human nature to exercise and to yield authority, greatly stimulated and aided by imitation of the absolute control exercised by the civil government. 5. Even after this change had taken place, the episcopal office was regarded, theoretically, as possessing equal authority and honor. But gradations of rank began at once, practically, to arise similar to the gradations in civil government throughout the Roman empire. Bishops in the country and in the smaller towns or villages became subordinate to the bishop of the adjacent city. 6. As the chief city of each district had the civil rank of a “*metropolis*” or mother city, so the bishop of that city, styled metropolitan from his position, took the lead in the deliberations of the local synod as “*primus inter pares*,” and acted as the representative of his brother bishops in their intercourse with other churches. Thus, though all bishops were nominally equal, a superior dignity and authority came by general consent to be vested in the metropolitans. 7. A still higher dignity was assigned to the bishops of the chief seats of government—Rome, Alexandria, and Antioch; and among these the bishop of Rome, the capital of the empire, had precedence. 8. Convenience dictated that the ecclesiastical divisions should follow the civil divisions of the empire. Roman emperors saw with amazement Christianity copying their jurisdiction in every part of the land. As the struggle deepened, the Christian bishop and the Roman governor became two rival authorities, the representatives of warring kingdoms within the same domain. When Christianity, instead of being destroyed, became the established religion, and the two administrations were made one, the resemblance between them was perfected, and the gradations of ecclesiastical rank which had grown up by custom were ordained by law. The empire was divided, as to its secular government, into four prefectures; these were subdivided into dioceses, and the dioceses into provinces. The rulers of cities and districts were subject to the governor of their province; the governors of provinces to the governor of their diocese; the governors of dioceses to their prefect; and the prefects to the emperor. In like manner, the bishops of cities and districts were subjected to the metropolitan of their province; the metropolitans of the provinces to the metropolitan of their diocese; the metropolitans of the dioceses to the patriarch

of one of the chief cities (of which there were now four), Rome, Constantinople, Alexandria, and Antioch; and the patriarchs of these cities, like the prefects, had, at first, no superior except the emperor. 9. Theoretically, all these primatial sees were co-ordinate in authority and mutually independent. But by degrees the bishops of the more important cities overshadowed their brethren, and exercised a supremacy which, though due rather to custom than to recognized claims, was increasingly acquiesced in from the manifest advantage of having a strong central power which could interfere in theological controversies or ecclesiastical disputes with an authority to which all would bow. 10. As the cities, Rome and Constantinople were both capitals of the empire, so their bishops were exalted above all others. And as these two cities became rivals for the supreme place, so the two bishops contended with each other for the first place as universal bishop. 11. At length the western and eastern churches were torn asunder. With the decline of the empire, the grandeur of the eastern church was obscured, until both empire and church were overwhelmed by the Ottoman power and the Mohammedan faith. With the rise of new kingdoms and the conversion of new nations in the west, the bishop of Rome was lifted up as "the head of the universal church."

EPISCOPAL CHURCH, PROTESTANT, is the title of that portion of the Christian church in the United States which, before the revolution, was a part of the church of England. Its history is naturally divided into two periods. I. *During colonial times.* The settlement of Jamestown was commenced in 1607. Its charter required that the true word and service of God should be preached, planted, and used according to the rules and doctrine of the church of England, not only in the colonies, but also, as far as possible, among the savages around them. Rev. R. Hunt labored in his vocation with piety and zeal to the end of his life. After him, Rev. A. Whittaker acquired, by his devoted exertions, the title, "Apostle of Virginia." Under his instrumentality Pocahontas was converted and baptized. As the first colonists in Virginia were all members of the church of England, provision was made for ministerial support by allowing 1500 lbs. of tobacco and 16 barrels of flour, per annum, to each minister, and by setting apart in each new borough a portion of land for a glebe. Tithes were subsequently introduced. None but ministers who had received episcopal ordination could legally officiate in the colony. The officers and agents of the company, in their efforts to promote morality and religion, were exhorted "to employ their utmost care to advance all things appertaining to the order and administration of divine service according to the form and discipline of the church of England, carefully avoiding all factious and needless novelties, which only tend to the disturbance of peace and unity." As an endowment for a college, 10,000 acres of land were given and a large amount of money was collected. Great zeal in behalf of the conversion and education of the Indians was felt, and a strong hope was cherished that the contemplated institution would be very useful to them. But, in 1622, they conspired against the English and murdered many of them. This embittered the minds of the survivors, and arrested all plans for their advancement in education and religion. During the next half century, owing to political disturbances and other causes, religion greatly declined throughout the colony, so that in 50 parishes nearly all were destitute of glebe, parsonage, church, and minister. In 1685, Rev. James Blair came as missionary to Virginia, and having been appointed commissary to the bishop of London, exerted, during an administration of more than 50 years, a very great influence in restoring and enlarging the work of the Episcopal church. By his efforts the college of William and Mary was founded in 1692. The colony of Maryland, founded in 1633 by lord Baltimore, a Roman Catholic, with 200 families and several priests, offered free admission "to every person professing to believe in Jesus Christ." At lord Baltimore's death, in 1676, there were 10 counties and 16,000 inhabitants, the majority of whom were Protestants. On the accession of William of Orange, "a Protestant revolution" took place, and a royal governor was sent into the colony. In 1692, the church of England was established by law, the province was divided into 30 parishes, and tithes for the support of the Episcopal ministers were imposed on every inhabitant, no matter what were his religious preferences and creed. Dr. Thomas Bray was appointed commissary of the bishop of London for the province of Maryland. By his efforts before leaving England, the societies "for promoting Christian knowledge," and "for the propagation of the gospel in foreign parts," were established. After his arrival in Maryland he entered with zeal into his work, and was active in having a bill passed, in which it was provided, "that the Book of Common Prayer and administration of the sacraments, with the rites and ceremonies of the church according to the use of the church of England, the psalter, and psalms of David, therein contained, be solemnly read by all and every minister or reader in every church, or other place of public worship, within this province." Dr. Bray's actual residence in Maryland was soon interrupted, but his zeal in behalf of the church of England, as established therein, continued to the close of his life. At this date a majority of the inhabitants are reported as in communion with that branch of the church.—In the colonies of Carolina and Georgia Episcopal churches were planted and continued to flourish. New York was first colonized by the Dutch in 1615, and, in its religious opinions and forms, was Presbyterian. In 1664, it was seized by the English. After this, precedence was given to the church of England, and a tax levied for its

maintenance. Trinity church, New York city, was founded in 1696; its first rector, Rev. W. Vesey, was also for half a century commissary of the bishop of London. This corporation is now celebrated for its great wealth. In New Jersey the early settlers were principally Quakers, Presbyterians, and Congregationalists; but all other Christians enjoyed entire religious liberty. Missionaries of the society for propagating the gospel worked earnestly and with good effect in the establishment of Episcopal churches. In Pennsylvania the first church of this order was Christ's church, Philadelphia, founded in 1695; and at various other points missionaries of the English society engaged in successful work. The first colonies of New England, composed chiefly of English Puritans and Separatists, who came to America mainly to escape the restrictions and oppressions to which they had been subjected by church laws at home, sought to exclude episcopacy. Because of the severe measures adopted for this purpose, and from other causes, for 60 years after the landing of the pilgrims there were no Episcopal churches in New England. In 1679, Charles II., on the earnest representation of some of the inhabitants, had one built in Boston. From that time, through the efforts of the English missionary society, some progress was made. Missionaries were sent to various points, who were honest, faithful, and laborious in traveling and preaching the gospel. If the church of England had appointed bishops for the colonies, the growth of the denomination therein would doubtless have been greater and more rapid. II. *After the attainment of national independence.* At the beginning of the revolution there were in the middle and eastern states about 80 Episcopal ministers, many of whom had received a large part of their support from the English society. After the war, aid from that source was, of course, withdrawn. Many of the ministers and people had adhered to the crown during the struggle, and at its close left the country. Soon after, the landed endowments of the church of England in Virginia were lost, and Episcopalians were thrown on their own resources. They were poor, and their prospects were not bright. Two things were necessary—to secure union among the churches of the several states, and to obtain bishops. The first was accomplished by instituting the general convention, (q. v.), which has ever since been accepted as the governing body of the Episcopal church in the United States. The first American consecrated to the episcopal office was bishop Seabury, who, about 1785, obtained consecration from Scottish bishops. In 1789, William White and Samuel Provoost were consecrated, by the archbishop of Canterbury and other English bishops, as bishops of Pennsylvania and New York; and, in 1790, James Madison was consecrated, also by English bishops, as bishop of Virginia. In arranging the order of common prayer the English prayer-book was retained, with such alterations as the political changes had made necessary, and with some other modifications. It came into immediate use, and has since been maintained without material alteration. The Episcopal church having thus early organized itself in accordance with the new life of the country, soon began to increase. It is now strong in large cities and flourishing towns; has many adherents among persons of wealth and culture; and, aided by its complete and zealous organization of the church as a missionary society, not only continues to increase in the older states, but also extends its churches and dioceses over all parts of the land. It is steadily subdividing its dioceses, and is considering the expediency of arranging them all, according to geographical position, into four provinces, to be united under a council that shall meet once in a fixed term of years. The doctrine of the American Episcopal church is that of the church of England, "which while it receives the Holy Scriptures as the ultimate rule of faith, does not throw them open to the varying interpretations of every man's private judgment, but explains them by the creeds, by definitions of Christian doctrine made by the general councils, and by the aid of traditions which it believes to have come down through an unbroken line of teachers from the apostles themselves." Besides the general theol. sem., numerous schools and colleges are under the control of the diocesan bishops. The domestic and foreign missionary soc., the American church building fund commission, and the fund for the relief of widows and orphans of deceased clergymen are the only societies managed by the general convention; there are 16 other important societies connected with the church. There are 14 newspapers. The centennial anniversary of the consecration of bp. Seabury, the first bishop of Conn., was celebrated in many churches, 1884. At the general convention of 1883, it was proposed to erase the words *Protestant Episcopal* from the title page of the Book of Common Prayer, and although not carried, there are many who believe that the name will be dropped before long, and that the body will adopt as its legal title the designation of the *American Catholic* church. The most important work accomplished by this convention was the adoption, with certain amendments, of the report of the joint committee on liturgical additions to the Book of Common Prayer. No changes affecting the doctrines of the church were made; and many of the additions are taken from the original English book, while permission is granted to use shortened forms of service at missions, or where the same office is used more than once on the same day. The *Book Annexed*, embodying all the additions proposed by the committee, was published, 1885. Final action was taken on the subject by the general convention of 1886, which adopted many of the proposed changes.

The following general summary of statistics for 1895-6 is taken from the *Protestant Episcopal Almanac* for 1897:

| | |
|---|-----------------|
| Dioceses in the United States | 58 |
| Missionary Jurisdictions in the United States..... | 21 |
| Missionary Districts in Foreign Lands..... | 7 |
| Clergy (Bishops, 83; Priests and Deacons, 4,640)..... | 4,723 |
| Parishes and Missions | 6,286 |
| Candidates for Holy Orders | 563 |
| Ordinations: Deacons. | 189 |
| Ordinations: Priests..... | 165 |
| Baptisms..... | 64,168 |
| Confirmations | 45,154 |
| Communicants | 641,145 |
| Marriages | 17,779 |
| Burials..... | 33,300 |
| Sunday-School Teachers | 45,236 |
| Sunday-School Scholars..... | 421,523 |
| Grand Total of Contributions | \$12,685,880.01 |

EPISCOPAL SYSTEM, in the Roman Catholic church, is the name given to the theory which vests the supreme ecclesiastical power in the whole body of bishops. It was urged most powerfully in the conflicting papal elections which occurred during the 14th century. All who adopted it declared that the general councils of the church were above the pope. Among this class the university of Paris and the Gallican church were conspicuous. The theory continued to spread, also, in Germany, where Nikolaus von Hontheim, co-adjutant bishop of Treves, was one of its chief supporters, and, in 1763, wrote his celebrated book concerning it. In 1785, the archbishops of Treves, Mayence, Cologne, and Salzburg, agreed in demanding from the pope the restoration of the episcopal privileges which had formerly been vested in the German archbishops. But the declaration of the infallibility of the pope by the Vatican council has put an end to all debate on the subject.

EPISCOPIUS, SIMON (whose Dutch name was Bisschop), the head of the Arminian party after the death of Arminius, was b. at Amsterdam in 1583, studied at Leyden, took his degree in 1606, and was ordained pastor of the village of Bleywyck near Rotterdam in 1610. In the following year, the states-general, with the intention of putting an end to the agitations created by the controversies between the Gomarists or Calvinistic party and the Arminians or Remonstrants, ordered a conference to be held in their presence at the Hague between six ministers of each party. E. was one of the six charged with the advocacy of Arminianism, and highly distinguished himself by his good temper, ability, and learning. In 1612, the curators of the university of Leyden appointed him professor of theology in the room of Gomar, who had gone to Seeland. This enraged the leaders of the orthodox party, who unscrupulously accused him of Socinianism, and of having entered into an alliance with the Roman Catholics for the destruction of Protestantism. By this means the fanaticism of the populace was roused against him; he was insulted and abused in the street, and on one occasion narrowly escaped being stoned to death. The house of his brother in Amsterdam was also sacked, under the pretext that it was a rendezvous of the Remonstrants. In 1618, occurred the famous synod of Dort (q.v.). E. was present, along with several other Arminians. The Calvinists, who happened to be in an overwhelming majority, would not allow him to speak; they told him that the synod was met not to discuss, but to judge; and, in fact, the whole proceedings exhibited as revolting a specimen of high-handed tyranny as any on record, even among ecclesiastical tribunals. Expelled from the church, and banished from the country, E. betook himself first to Antwerp, and afterwards to Rouen and Paris, but in 1626 returned to Rotterdam, where the *odium theologicum* against his party had become less virulent. Here he married in 1630. Four years after, he was made primarius professor of divinity in the newly-established college of the Remonstrants in Amsterdam. He died in 1643. His chief works are his *Confessio Remonstrantium* (1621) and *Apologia pro Confessione* (1629).

EPISTATES, the title of the presiding officers of the great councils of the Athenians, the Ecclesia and the Council of Five Hundred. The E. held office for only one day at a time.

EPISTAXIS, hemorrhage from the nose. For full treatment see NOSTRILS, DISEASES OF THE.

EPISTLE. The lesson in the church service called the E., derives its name from being most frequently taken from the apostolic epistles, although it is sometimes also taken from other parts of Scripture. This part of the service is believed to be as old as the 6th century.

EPISTLE SIDE OF THE ALTAR, the left side of the altar or communion table, looking from it, at which in the church service the epistle of the day is read. It is of lesser distinction than the right or gospel side, and is occupied by the clergyman of lower ecclesiastical rank. The reader of the epistle was in former times called the epistler.

EPISTLES, **SPURIOUS**, have been forged by various unknown authors, and for a variety of purposes. Many of them are lost, but a considerable number are extant, among which are the following: 1. *The Epistle of Paul to the Laodiceans*.—In the early

part of the 2d c. there was a Greek epistle with this title. It was received by the heretic Marcion, but is generally believed to have been a forgery founded on Paul's direction to the Colossians to read the epistle from Laodicea. "Some," said Theodoret in the 5th c., "imagine Paul to have written to the Laodiceans, and accordingly produce a certain forged epistle; but the apostle does not say *to*, but *from*, the Laodiceans." There is also an epistle with this title now extant in Latin, which, however, cannot be proved to be a translation of the former, but has, probably, a comparatively modern origin. It was first published in 1517, but existed in manuscript, at an earlier date, in the library of the Sorbonne. 2. *The Third Epistle of Paul to the Corinthians*.—Many persons have inferred from several passages in the two genuine epistles that Paul wrote a third which is not in the canon. There is still extant in the Armenian language an epistle professedly from the Corinthians to the apostle, with his reply. It was quoted in the 3d c. by Gregory, the illuminator, first bishop of Armenia, but has not been noticed by any ancient Greek or Latin writer. 3. *The Epistle of Peter to James* was forged in very early times, and is supposed to have been used as an introduction to the *Preaching of Peter*, which was held in great esteem by some early Christian writers, and was considered a genuine work by Clement of Alexandria (about the end of the 2d c.), Theodotus of Byzantium, and others. It was used by the heretic Heraclion in the 2d century. Origen (first half of 3d c.) did not receive it as the work either of Peter or of any other inspired person. Its author, perhaps, was one of the Ebionites at the opening of the 2d century. 4. *The Epistles of Paul and Seneca* comprise eight long letters in Latin from the philosopher Seneca to the apostle Paul, and six from Paul to Seneca in reply. They are certainly ancient. Jerome (about the end of the 4th c.), supposing them genuine, valued them highly, and was led by them to place Seneca in his catalogue of saints. At that time they were read by many. Augustine (about the same time) also speaks of them as genuine. Some learned men of more modern times accept them, but by far the greater number pronounce them spurious. 5. *The Epistle of Publius Lentulus*, written from Jerusalem to the Roman senate. It contains (but with many variations of the text) the following oft-quoted description of the personal appearance of Christ: "A man of tall stature, good appearance, and a venerable countenance, such as to inspire beholders with both love and awe. His hair, worn in a circular form and curled, rather dark and shining, flowing over the shoulders, and parted in the middle of the head, after the style of the Nazarenes. His forehead smooth and perfectly serene, with a face free from wrinkle or spot, and beautified with a moderate ruddiness, and a faultless nose and mouth. His beard full, of an auburn color, like his hair, not long but parted. His eyes quick and clear. His aspect terrible in rebuke, placid and amiable in admonition, cheerful, without losing its gravity: a person never seen to laugh, but often to weep." Dr. Edward Robinson, after a careful examination of the whole subject, comes to the following judgment: "*In favor of the authenticity of the letter we have only the purport of the inscription. There is no external evidence whatever. Against its authenticity we have the great discrepancies and contradictions of the inscription; the fact that no such official person as Lentulus existed at the time specified, nor for many years before and after; the utter silence of history in respect to the existence of such a letter; the foreign and later idioms of its style; the contradiction in which the contents of the epistle stand with established historical facts; and the probability of its having been produced at some time not earlier than the 11th century.*" 6. *An Epistle of the Virgin Mary*, said to have been written in Hebrew, but extant in Latin, addressed to the Christians of Messina, and giving name to the metropolitan church of "Our Lady of the Letter." 7. *An Epistle of the Virgin* to the Florentines. 8. *From the same* to Ignatius, with his reply. There exist also spurious letters attributed to Plato, Aristotle, and Cicero.

EPISTOLÆ OBSCURORUM VIRORUM (Lat. Letters of Obscure Men) is the title of a collection of satirical letters which appeared at the commencement of the 16th c., and professed to be the composition of certain ecclesiastics and professors in Cologne and other places in Rhenish Germany. They were directed against the scholastics and monks, and lashed with merciless severity their doctrines, writings, morals, modes of speech, manner of life, follies and extravagances, and thus helped in no small degree to bring about the reformation. The controversy of Reuchlin with the baptized Jew, Pfefferkorn, concerning Hebrew punctuation, gave the first occasion to the *Epistolæ*, and it is probable that their title itself was suggested by the *Epistolæ Clarorum Virorum ad Reuchlinum Phorcensum* (1514). They were addressed to Octuin Gratus in Deventer, who was by no means so complete an ignoramus as might be supposed from this circumstance, but who had made himself odious to the liberal minds of the time by his arrogant pretension and his determined hostility to the spirit of his age. On the first appearance of the work, it was fathered on Reuchlin; afterwards, it was ascribed to Reuchlin, Erasmus, and Hutten. More recent investigators have inclined to the belief, that the *first* part, which appeared at Hagenau in 1515 (but professedly at Venice), was the production of Wolfgang Angst, a learned and witty book-printer of that town; but, latterly, doubt has also been expressed whether even he had anything to do with the *Epistolæ*. In the composition of the second part (published in 1519), after Ulrich von Hutten, Erotus Rubeanus had the most considerable share. The circumstance of the *Epistola* being placed in the catalogue of forbidden books by a papal bull, helped to spread it not a

little. Among the numerous editions of the work (1643, 1703, 1827, etc.), the best is that by Böcking (1858; 2d ed. 1864). See Mark Pattison's *Essays* (1889).

EPISTOLER, or **EPISTLER**, an officer in the English church, who, in accordance with the canon, assists the celebrant in the administration of holy communion. His duty is to read the liturgical epistle, and from this fact he derives his name. See **GOSPELERS**.

EPISTYLIUM, or **EPISTYLE** (Gk. *Epistulion*; from *Epî*, upon, and *stylos*, a pillar), a huge lintel of stone or wood, resting upon the abacus of the capital of a column or pillar. Instead of epistylum the term *architrave* (q. v.) is now employed. See **COLUMN**.

EPI TAPH (Gr. *epî*, upon, and *taphos*, a hillock, mound, or other monument placed over a grave). From originally signifying a monument, this word is now used exclusively to designate the inscription commemorative of the deceased which is placed upon the monument. This perversion may in some measure have arisen from the remembrance of the funeral orations which the ancients were in the habit of pronouncing at funerals. But the E., in its stricter sense, was well known to the classical nations of antiquity; and, indeed, by every people a brief commemoration of the heroic actions or personal virtues of their illustrious dead has been regarded as one of the worthiest occupations of the faculties of the living. As epitaphs were not only engraved on the most enduring substances, but from their brevity were easily preserved in the memory and orally transmitted, wherever we find the literature of a people at all we are pretty sure to discover specimens of their epitaphs. Pettigrew has translated several from Egyptian sarcophagi (Bohn's edition, p. 5), but they are of no great interest. Herodotus (vii. 228) has preserved to us those which the Amphictyons caused to be inscribed on the columns which they raised in honor of the heroes of Thermopylæ, and that which Simonides, from personal friendship, placed on the tomb of the prophet Megistias. The general inscription for the whole of them was to this effect: "Four thousand from Peloponnesus once fought on this spot with three hundred myriads;" and that which was special to the Spartans was still more memorable: "Stranger, go tell the Lacedæmonians that we lie here obedient to their commands." The *Anthologia Græca*, edited by Brunk, and subsequently by Jacobs, contains the largest collection of Greek epitaphs: of these many were translated and published by Bohn in 1854, under the editorial care of Mr. George Burges. Of Roman epitaphs, every antiquarian museum even in this country presents numerous examples; for the form in which they were conceived was adopted by our own Romanized forefathers, and many a stone bearing the well-known *D. M. (Dis Manibus)*, or *Siste Viator*, probably covered the remains of those whose veins never contained a drop of Roman blood. A very interesting collection of early Christian epitaphs will be found in Dr. Charles Maitland's *Church in the Catacombs*, published in 1846. The naturally epigrammatic turn of the French mind peculiarly adapts it for this species of composition, and in French collections, such as the *Recueil d'Epitaphes*, very felicitous examples are to be found both in Latin and in French. Of the former may be mentioned the "Tandem felix!" which the count de Tenia, who had enjoyed every form of temporal prosperity, caused to be engraved on his tomb; and of the latter, the touching E. to a mother, "La première au rendez-vous." A large portion of the earlier monuments, and consequently of the epitaphs of this country, were destroyed at the reformation, and subsequently by the iconoclastic rage of the Puritans and Presbyterians. But when we come down to a later date, the literature of no people, either ancient or modern, can vie with our own in this peculiar branch, for whilst English epitaphs possess the point and terseness without which no E. can be successful, they exhibit a feature almost unknown in those of other nations—that, viz., of wit, or more properly speaking, perhaps, of humor. It seems as if the wittiest people in the world, as the English unquestionably are, had found it impossible to confine their raillery to the living, and accordingly we find that the harmless peculiarities of the dead have often been hit off on a tombstone, with a felicity which has rendered immortal what otherwise the next generation must have forgotten. Of this class of epitaphs our collections present an almost infinite variety. There are many excellent old collections of epitaphs, such as the *Thesaurus Epitaphiorum* of Philip Labbe, Paris, 1666. Of modern ones, the best is that of Pettigrew, published by Bohn.

EPI THALA MIUM was a species of poem which it was the custom among the Greeks and Romans to sing in chorus near the bridal-chamber (*thalamus*) of a newly-married couple. Anacreon, Stesichorus, and Pindar composed poems of this kind, but only scanty fragments have been preserved. The epithalamium of Peleus and Thetis by Catullus is one of the finest specimens of Latin poetry extant; but probably the most gorgeous epithalamium in all literature, is that of the English poet Spenser. A collection of Greek and Latin epithalamia is to be found in Wernsdorf's *Poetæ Latini Minores* (4th vol., part 2).

EPI THELIO MA, a variety of cancer, attacking surfaces covered with epithelium or epidermis. See **CANCER**.

EPI THE LIUM is the term applied in anatomy to the cell-tissues which, in layers of various thickness, invests not only the outer surface of the body, and the mucous membranes connected with it—as, for example, those of the nose, lungs, intestinal canal etc.—but also the closed cavities of the body, such as the great serous membranes, the ventricles of the brain, the synovial membranes of joints, the interior of the heart

and of the blood-vessels proceeding to and from it, the ducts of glands, etc.

The thickness of this tissue varies extremely with the position in which it occurs. In some parts it consists of numerous strata of cells, collectively forming a layer of more than a line in thickness; in other parts, it is composed of only a few strata, or often of only a single stratum of cells, and can only be detected by the microscope.

The cells of which the E. is composed are usually soft nucleated cells; they may be rounded, polygonal, fusiform, cylindrical, or conical in shape, and sometimes they possess vibratile cilia, the appearance and uses of which will presently be explained.

In his *Manual of Human Histology*, Kölliker adopts the following arrangement. He considers (a) E. in a single stratum, and (b) E. in many layers.

(a) *Epithelium in a single stratum* may be composed of:

1. *Rounded, polygonal cells*, constituting the variety known as pavement or tessellated E., and occurring as an investment of the serous membranes of most synovial membranes, of the lining membrane of the heart and of the veins, of the canals of glands, etc.

2. *Fusiform, superficially united cells* (fusiform E.), as the E. of the arteries and of many veins.

3. *Cylindrical cells* (cylinder E.), as in the intestine from the stomach to the termination of the alimentary canal, in the excretory ducts of all the glands opening into the intestine, etc. Various illustrations of this cylinder E. are given in the article DIGESTION, ORGANS AND PROCESS OF.

4. *Cylindrical or conical ciliated cells*, as the E. of the more minute bronchial tubes, of the nasal cavities, and of the uterus.

5. *Rounded ciliated cells*, as the ciliated pavement E. of the ventricles of the brain in the fetus.

(b) *Epithelium in many layers* may be composed of:

1. *Cylindrical or rounded cells below, and more or less flattened cells above*. This is termed laminated pavement E., and occurs in the mouth, lower part of pharynx, esophagus, bladder, etc.

2. *Rounded cells below, more elongated ones in the middle, and ciliated conical ones above*. This is termed laminated ciliary E., and occurs in the larynx, trachea, and larger bronchial tubes, in the greater part of the nasal cavity, etc.

In all the varieties of E., the layer of external cells is being constantly disintegrated and replaced by the layer immediately beneath.

The uses of the chief varieties of E., especially of ciliated E., require some notice.

The polygonal or pavement E. mainly acts like the epidermis, as a protecting medium to the soft parts beneath.

The cylindrical E. additionally takes an active part in the process of secretion. Illustrations of the function of the cells forming this variety of E. are given in the articles CELLS, ANIMAL: DIGESTION, ORGANS AND PROCESS OF; and the subject will be further noticed under the head SECRETION.

In connection with ciliated E., we must notice *ciliary motion* generally, in so far as it occurs in the animal kingdom. Certain surfaces which are lubricated by a fluid, are covered with a multitude of hair-like processes of extreme delicacy and minuteness (their length varying from $\frac{1}{1000}$ to $\frac{1}{12500}$ of an inch), which from their shape are termed *cilia*, from *cilium*, an eyelash. During life, and for a certain period after death, these filaments exhibit a remarkable movement, each cilium bending rapidly in one direction, and rapidly returning to its original position (according to Krause, these movements range from 190 to 230 in a minute). On examining a ciliated surface with a high magnifying power, the motion presents an appearance somewhat resembling that of a corn-field agitated by a steady breeze. Any minute objects coming in contact with the free extremities of the cilia are urged onward in the direction of the predominant movement: and the best method of observing the course of the ciliary current is to sprinkle the surface with a little powdered charcoal, grains of which may speedily be seen to move onwards in a definite direction.

An easy way to observe this phenomenon is to detach, by scraping with a knife, a small piece of E. from the back of the throat of a living frog. The scales, moistened with water or serum, will continue to exhibit the movement of their adherent cilia for a very considerable time, provided the piece be kept duly moistened. On one occasion, a piece prepared in this way by Mr. Bowman and Dr. Todd exhibited motion for 17 hours; and it would probably have continued doing so for a longer time, had not the moisture around it evaporated; and if the E. is not removed from the body of an animal that had been killed, the motion continues much longer. In a turtle, after death by decapitation, it lasted, in the mouth, 9 days; in the trachea and lungs, 13 days; and in the esophagus, 16 days. In man and mammals, it seldom lasts 2 days, and usually ceases much sooner. The necessary condition for their movement appears to be the integrity of the cells to which they are attached; for as soon as these shrink up for want of moisture, or undergo any physical change, the cilia cease their characteristic action.

This phenomenon exists very widely throughout the animal kingdom. Dr. Sharpey, in his article CILIA* (published upwards of 40 years ago), notices its occurrence in the

* In the *Cyclopædia of Anatomy and Physiology*.

infusoria, in polyps and their ova, in acalephæ, actiniæ, echinodermata, annelida, mollusca, and the molluscoids (e.g., ascidians), in reptiles, birds, and mammals. Since the date of that article, it has been discovered in sponges, and in one or two exceptional cases in fishes; but it has never been found in any part of the body of articulates (crustaceans, insects, or arachnidans). The parts on which it occurs are (1) the skin or surface of the body, (2) the respiratory, (3) the alimentary, and (4) the genito-urinary systems; and it has been observed in the ova of numerous classes of animals, from reptiles downwards to infusoria. In most of the parts in which we observe it, its use appears to be of a mechanical nature—viz., to convey the fluids or other matters along the surfaces on which the cilia exist, or, as in the infusoria, to carry the entire animal through the water.

1. Cilia have been found on the external surface in batrachian larvæ, in mollusca, annelida, echinodermata, actiniæ, medusæ, polypi, and infusoria. In most cases, their function is respiratory, but in many instances it is also locomotive or prehensile.

2. Ciliary motion has been observed on the lining membrane of the air-passages of mammals, birds, and reptiles, where, whatever may be its other uses, it serves to convey the secretions along the membranes, together with any foreign matters that may be present. It exists also on the external gills of batrachian larvæ, and on the respiratory organs of mollusca and annelida. The cilia which exist externally on still lower animals without separate respiratory organs, assist in the respiratory process, by renewing the water on the surface.

3. It occurs in the mouth, throat, and gullet of various reptiles, and the alimentary canal of the mollusca, echinodermata, many annelida, and acalephæ. It is not easy, as Dr. Sharpey observes, to see the purpose of the motion in all these cases. In some, it may merely convey secreted matters along the surface of the lining membrane; and in others it seems to serve in place of ordinary deglutition, to carry food into the stomach.

4. It is observed on the surface of the reproductive organs of mammals, birds, and reptiles. From the direction of the current being from without inwards, the office of the cilia may be to hurry down the ovum, in addition to removing the mucous secretion of the membrane.

In reptiles and fishes, ciliary motion exists at the neck of each uriniferous tube. The movement is directed towards the tube, and favors the flow of the watery portion of the secretion towards it.

There are some situations, both in man and the lower animals, in which it is difficult to determine what functions the ciliary motion can perform, as, for example, in man, in the ventricles of the brain; and in the frog, in the closed cavities of the pericardium and peritoneum.

EPIZOÏA. This term is applied to those parasitic creatures which live on the bodies of other animals, and derive their nourishment from the skin. Our space will only allow of our noticing those that infest man. They may be divided into two groups: (1) Those which live upon the surface of the skin, and (2) those which live in the skin. Fleas, lice, bugs, ticks, etc., belong to the first group; the itch-insect or *sarcoptes*, the pimple-mite or *demodex folliculorum*, and possibly some other species of the *acarida*, to the second.

In a zoological point of view, all the E. that infest the human subject are insects or arachnidans. The parasitic insects are: I. *Pulicida*, or fleas, including—1. The common flea, or *pulex irritans*; 2. The sand-flea, or *pulex penetrans*, known also as the chigo, chigger, etc. II. *Acanthida*, or soft bugs, including the common bed-bug or *acanthia* (s. *cimex*) *lectularia*. III. *Pediculida*, or lice, including—1. The common louse, or *pediculus capitis*; 2. The body louse, or *pediculus vestimenti*; 3. The crab louse, or *pediculus* (s. *phthirius*) *pubis*; 4. The louse occurring in phthiriasis, or *pediculus tabescentium*.

The parasitic arachnidans belong to the order of *acarida*, or mites; indeed, most of the animals forming the different families of this order lead a parasitic existence. We have—I. *Demodicida*, including the pimple-mite or *demodex* (s. *acarus*) *folliculorum* (the dog and the sheep possess each a special demodex. II. *Sarcoptida*, including the itch-mite or *sarcoptes* (s. *acarus*) *scabiei*. (Most of our domestic animals seem to be infested by a special sarcoptes, the species of which are numerous.) III. *Ixodida* or ticks, including—1. The American tick or *ixodes hominis* (common in Brazil); 2. The common wood-tick (dog's tick), or *ixodes ricinus*. There are probably many species of ixodes which are occasionally found on man. IV. *Gamasida*, or beetle lice, including—1. The bird-mite, or *dermanyssus avium* (occasionally found on sickly persons); 2. The Miana bug, or *argas persicus* (common in some parts of Persia, and especially at Miana); 3. The chinch bug, or *argas chinche* (occurring in Columbia). V. *Orobatiida*, or grass-lice, including the harvest-bug, or *leptus autumnalis*. See the articles BUG, FLEA, ITCH-MITE, LOUSE, TICK.

EPIZOÏTICS (Gr. *epi*, upon, and *zōon*, an animal) are diseases of animals which manifest a common character, and prevail at the same time over considerable tracts of country. Like epidemics, they appear to depend upon some peculiar and not well ascertained atmospheric causes; where the cases are neglected or overcrowded, they also frequently become contagious; they are apt to take on a low type of fever, and

are better treated by supporting than by reducing remedies. Influenza in horses, and pleuro-pneumonia and vesicular epizootic in cattle, are examples.

EPOCH, in astronomy, is an abbreviation for "longitude at the E.," it means the mean heliocentric longitude of a planet in its orbit at any given time—the beginning of a century, for instance. The E. of a planet for a particular year is its mean longitude at mean moon, on Jan. 1, when it is leap year, and on Dec. 31 of the preceding year, when it is a common year. The E. is one of the elements of a planet's orbit.

EP' OCH, in chronology. See **CHRONOLOGY**.

EP' ODE is the last part of the chorus of the ancient Greeks, which they sung after the strophe and antistrophe, when the singers had returned to their original place. The E. had its peculiar measure of syllables and number of verses. See **CHORUS**.

EPPING, a t. in the w. of Essex co., England, in a pleasant healthy situation, at the n. end of E. forest, 16 m. n.n.e. of London. It has a very irregular appearance. Pop. '91, 2565. It is noted for its cream, butter, sausages and pork. It sends large quantities of butter to London. E. royal forest, formerly under the name of Waltham forest, where the ancient kings enjoyed much sport, covered all Essex, and extended almost to London. It is now limited to a comparatively small area in the s. w. part of the county and only a small part of this tract is in wastes and woods, the rest being now inclosed as private property. In the forest, 5 m. from E. is queen Elizabeth's hunting-lodge. Separated by the river Roding from E. forest is Hainault forest, lately disforested. Here for many centuries a fair was held under the enormous Fairlop oak, not now existing, and a stag was yearly turned out in the forest on Easter Monday, for the amusement of the public. At the cost of about half a million of money, 5600 acres of E. forest were bought by the corporation of London, and declared free to the public in 1882.

EPROUVETTE is a machine for proving or testing the strength of gunpowder. It was invented or suggested in the last century by Robins, but was greatly improved by Dr. Hutton.

The *gun* E. determines the strength of gunpowder by the amount of recoil produced. A small gun, usually a "half-pounder," is fixed to the lower end of an iron rod; its base being adjusted to an arm projecting from the rod; or else it is suspended from an iron frame. A horizontal steel axis is fixed to the rod or frame about which the gun may vibrate. A pointed iron rod or style projects downwards from the lower side of the gun, and touches a groove filled with soft wax; the groove is so shaped that, when the gun recoils, the point cuts a path for itself along this wax; and the length of this path determines the amount of recoil. Sometimes a brass graduated arc with an index is used instead of the pointed style and the waxed groove; but the principle of action is just the same. On the arc the recoil should vary from 26° for new fine-grain powder to 20° 5' for old powder of coarse grain. This system of proof is resorted to annually at minor and foreign stations for the proof of all powder in store, to ascertain the amount of deterioration; five rounds constitute the minimum proof. Before the E. is resorted to, the powder must pass the test of specific gravity, by weighing not less than 55 lbs. to the cubic foot.

The *mortar* E. determines the strength of gunpowder by the distance to which a ball is projected, instead of the distance to which the piece recoils. It is generally a mortar of 8-inch bore, in which 2 to 4 ozs. of powder is employed to propel an accurately turned iron shot to a distance of about 120 yards. Other things being equal, the strongest gunpowder sends the shot to the greatest distance; and this is the usual mode adopted in testing gunpowder supplied to the government by various contractors.

The ordinary E. is an instrument shaped like a small pistol without a barrel, and having its breach chamber closed by a flat plate connected with a strong spring. On the explosion of the powder against the plate, it is driven back to a distance indexed according to the strength of the powder, and is retained at its extreme state of propulsion by a ratchet wheel.

EPSOM (said to have originally been Ebbasham) is a small market t. on the margin of the Banstead downs in Surrey, 15 m. s.s.w. of London by road, and 14 m. by the London and Southwestern railway. The famed sulphate of magnesia springs of E. gave their name to the E. salts formerly manufactured from them. This manufacture has been abandoned from the ease with which these salts can be made artificially. The royal medical college, erected on the Downs, and established in 1851, provides education for about 170 boys, the sons of medical men, and affords a home to decayed members of the profession and their widows. Pop. '91, 8417. On the Downs, 1½ m. s. of the town, the famous E. horse-races are held yearly. They are said to have been instituted by Charles I., but have become of greater importance since the institution of the Derby stakes in 1780 (see **DERBY DAY**). The races last four days, and as many as 100,000 persons often assemble to witness the most important of them.

EPSOM SALT, or **SULPHATE OF MAGNESIA** ($MgSO_4 + 7H_2O$), occurs not only in the water of mineral springs, as at Epsom, Seidlitz, and many other places; but also as an efflorescence on the surface of various rocks, sometimes along with alum, as at Hurlet, in Renfrewshire; and on the ground, as in some parts of Spain and of the Russian

steppes. It sometimes occurs snow-white and very pure, sometimes discolored by impurities; and is either in the form of fine thread-like crystals, or in crusts, flakes, granules, etc. Its crystals are prisms, almost rectangular. For purposes of commerce, it is obtained by the action of dilute sulphuric acid upon magnesian limestone. See **MAGNESIUM**.

E. S. is a well-known purgative remedy much in use in household medicine. It may be given in doses from 2 drams to 1 oz., according to the effect required, in a tumbler of water.

EPWORTH LEAGUE, a society formed in May, 1889, in the Methodist Episcopal church by the union of five societies then existing. Its objects are to promote the religious feeling of the young members and friends of the denomination, and fit them for works of charity and help. Its weekly organ is the *Epworth Herald*. On November 10, 1896, it reported 21,304 chapters, with a membership of 1,500,000. Among its features are the weekly prayer meeting and the "intellectual" and "mercy and help" departments. In 1896 the president was Bishop R. K. Hargrove, Nashville, Tenn.

EQUABLE MOTION is that by which equal spaces are passed over in equal times.

EQUALITY. See **LIBERTY, EQUALITY, FRATERNITY**.

EQUATION, ANNUAL, one of the most conspicuous of the subordinate fluctuations in the moon's motion, due to the action of the sun, which increases with its proximity to the earth and her satellite. It consists in an alternate increase and decrease in her longitude, corresponding with the earth's situation in its annual orbit, i.e., to its angular distance from the perihelion, and therefore having a year instead of a month, or aliquot part of a month, for its period. For an explanation of the mode of its production, the reader is referred to Herschel's *Outlines of Astronomy*, art. 738, *et seq.* The subject is too abstruse for explanation in this work.

EQUATION, DIFFERENTIAL, is an equation involving differential co-efficients (see **CALCULUS**); such is $\frac{d^2y}{dx^2} + a \frac{dy}{dx} = x$; from which it is required to find the relation between y and x . The theory of the solution of such equations is an extension of the integral calculus, and is a branch of study of the highest importance.

EQUATION, FUNCTIONAL. See **FUNCTIONS**.

EQUATION, LUNAR. See **LUNAR THEORY**.

EQUATION OF THE CENTER. If the earth moved uniformly round the sun in a circle, it would be easy to calculate its longitude or distance from the line of equinoxes at any time. One year would be to the time since the vernal equinox as 360° to the arc of longitude passed over. But the orbit of the earth is not circular, nor is its motion uniform; the orbit is slightly elliptical, and the motion is quicker at perihelion than at aphelion. The true rule, then, for ascertaining the earth's longitude is contained in the following proportion: one year is to the time elapsed as the whole area of the earth's orbit is to the area swept over by the radius vector in the time. This is a deduction from Kepler's law (see **CENTRAL FORCES**), that, in planetary motion, equal areas (not angles) are swept over in equal times. The area swept over being ascertained from the laws of the earth's motion, and the elements of its orbit, it is a question of geometry to ascertain the angle corresponding to the area, or the true longitude. In astronomy, the longitude, as calculated on the supposition that the earth moves uniformly in a circle, is called the *mean longitude* of the earth; and it happens, from the orbit being, as we said, but slightly different from a circle, that the mean and true longitude differ but slightly. The quantity by which the true and mean longitudes differ is called the *equation of the center*; and this is sometimes to be added to, and sometimes to be subtracted from the mean longitude, to obtain the true; and sometimes it is zero.

EQUATION OF EQUINOXES is the difference between the true position of the equinoxes, and the position calculated on the supposition that their motion is uniform. See **PRECESSION**.

EQUATION OF LIGHT. In astronomical observations, the visual ray by which we see any body is not that which it emits at the moment we look at it, but which it *did* emit some time before, viz., the time occupied by light in traversing the interval which separates it from us. If, then, the body be in motion, its aberration, as due to the earth's velocity, must be applied as a correction, not to the line joining the earth's place at the moment of observation with that occupied by the body, (as seen) at the same moment, but at that antecedent moment when the ray quitted it. Hence is derived a rule applied by astronomers for the rectification of observations made on a moving body, viz., from the known laws of its motion and the earth's, calculate its relative angular motion in the time taken by light to pass from it to the earth. This motion is the total amount of its apparent displacement. Its effect is to displace the body in a direction contrary to its apparent motion, an effort one part of which is due to aberration, properly so-called (see **ABERRATION**) resulting from the composition of the motions of the earth and of light, and another part to the fact of the passage of light occupying time. The *equation of light* is the allowance to be made for the time occupied by the light in traversing a variable space.

EQUATION OF PAYMENTS. The problem considered under this head in books of arithmetic is to find a time when, if a sum of money be paid by a debtor, which is equal to the sum of several debts payable by him at different times, no loss will be sustained by either the debtor or creditor. The rule generally given is as follows: Multiply each sum due by the time at which it is payable, and then divide the sum of the products by the sum of the debts: the quotient is the equated time. For example, if £10 be due at one month, and £20 at two months, find as an equivalent when the whole £30

may be paid at once. Ans. $\frac{10 \times 1 + 20 \times 2}{30} = 1\frac{2}{3}$ months. This rule is, however, incorrect where the debts are unequal, because it takes no account of the balance of interest and discount. A correct rule for the case of two debts and simple interest is subjoined. Let d and D denote the debts, t and T the times of payment, and r one year's interest on D . Then if $A = T + t + \frac{D+d}{dr}$, and $B = Tt + \frac{DT+dt}{dr}$, the equated time will be $\frac{1}{2}A - \frac{1}{2} \sqrt{A^2 - 4B}$. When three or more debts are concerned, the plan is to find by this formula the equated time for the first two, and then for their sum payable at their equated time, and the third, and so on. The common rule is, however, sufficiently correct for ordinary use.

EQUATION, PERSONAL, is a correction important chiefly in astronomical observations. Two observers, each of admitted skill, often differ in their record of the same event—as the passage of a star before the wires of a transit instrument—by a quantity nearly the same for all observations by those persons. This quantity is their relative personal equation. Each observer habitually notes the time earlier or later than the fact, by a minute and nearly uniform portion of a second. This quantity is his absolute personal equation. The correction is of no value when comparison is made between the records of the same observer, since each is in error in the same way, but it becomes important when the work of different observers is combined. The value and sign of the personal equation is found for each observer by the discussion of a large series of observations. It is a reliable correction for the work of only trained observers, who have, by long practice, acquired a habitual method of work which is uniform, even their errors conforming to a system.

EQUATIONS. An equation may be defined to be an algebraical sentence stating the equality of two algebraical expressions, or of an algebraical expression to zero. From another point of view, it is the algebraical expression of the conditions which connect known and unknown quantities. Thus (1), $xy = 24$, and (2), $x^2 + y^2 = 52$, are two E. expressing the relations between the unknown quantities x and y and known quantities. Generally, E. are formed from observations from which an object of inquiry may be inferred, but which do not directly touch the object. Thus, suppose we wish to ascertain the lengths of the sides of a rectangular board which we have no means of measuring, and that all the information we can get respecting it is, that it covers (say) 24 sq. ft., and that the square on its diagonal is (say) 52 sq. feet. From these facts, we can form E. from which we may determine the lengths of the sides. In the first place, we know that its area is equal to the product of its sides, and if we call these x and y , we have $xy = 24$, the first of the E. above given. Again, we know that the sum of the squares on the sides is equal to the square on the diagonal; hence, we have the second equation, $x^2 + y^2 = 52$. From these two E., we should be able to determine the values of x and y . The determination of these values is called the *solution* of the equations.

E. are of several kinds. Simple E. are those which contain the unknown quantity in the first degree; thus, $\frac{x}{2} + 3 = 4$, is a simple equation. Quadratic E. are those which contain the unknown quantity in the second degree: $x^2 + 5x - 36 = 0$, is a quadratic equation. Cubic and biquadratic E. involve the unknown quantity in the third and fourth powers respectively. For the higher E., there are no special names; they are said to be E. of the degree indicated by the highest power of the unknown which they contain. Simultaneous E. are those which involve two or more unknown quantities, and there must always be as many of them, in order to their determinate solution, as there are unknown quantities. The E. first mentioned—viz., $xy = 24 - x^2 + y^2 = 52$, are simultaneous equations. It may be mentioned, that in the course of solving such E., the principal difficulties encountered are always ultimately the same as in the solution of E. containing only one unknown quantity. For instance, in the E. just given, if we substitute in the second the value of y as given by the first, or $y = \frac{24}{x}$, we have $x^2 + \frac{(24)^2}{x^2} = 52$, which may be solved as a quadratic equation. The general theory of E., then, is principally concerned with the solution of E. involving one unknown quantity only, for to this sort all others reduce themselves. Indeterminate E. are such as do not set forth sufficient relations between the unknown quantities for their absolute determination, and which accordingly admit of various solutions. Thus, $xy = 24$ is an indeterminate equation, which is satisfied by the values $x = 3$, $y = 8$; or

$x = 6, y = 4$; or $x = 2, y = 12$. We require some other relation, such as $x^2 + y^2 = 52$, to enable us to fix on one of the sets of values, x and y , as those of x . For other kinds of E., see EXPONENT AND EXPONENTIAL, FUNCTIONS, and DIFFERENCE.

The object of all computation is the determination of numerical values for unknown quantities, by means of the relations which they bear to other quantities already known. The solution of E., accordingly, or, in other words, the evolution of the unknown quantities in them, is the chief business of algebra. But so difficult is this business, that, except in the simple cases where the unknown quantity rises to no higher than the second degree, all the resources of algebra are as yet inadequate to effect the solution of E. in general and definite terms. For E. of the second degree, or quadratic E., as they are called, there is a rigorous method of solution by a general formula; but as yet no such formula has been discovered for E. even of the third degree. It is true, that for E. of the third and fourth degrees general methods exist, which furnish formulas which express under a finite form the values of the roots. See CARDAN and CUBIC EQUATIONS. But all such formulas are found to involve *imaginary* expressions, which, except in particular cases, make the actual computations impracticable till the formulas are developed in infinite series, and the imaginary terms disappear by mutually destroying one another. What is called Cardan's formula, for instance (and all others are reducible to it), is in this predicament whenever the values of the unknown quantity are all real; and accordingly, in nearly all such cases, the values are not obtainable from the formulæ directly, but from the infinite series of which they are the compact expression. But though such formulæ as Cardan's are useless for the purpose of numerical computation, the search for them has led to most of the truths which constitute the general theory of E., and through which their *numerical solution* may be said to have been at last rendered effective and general. This method of numerical solution is a purely arithmetical process, performed upon the *numerical co-efficients* of E., and it is universally applicable, whatever the degree of the equation may be. With this method are connected the names of Budan, Fourier, Horner, and Sturm. We cannot here enter into an account of it; the reader should consult on the subject Young's *Theory and Solution of Algebraical Equations of the Higher Orders*; Peacock's *Treatise on Algebra*; and La Grange's work on *Numerical Solutions*.

The rules for the solution of the simpler forms of E. are to be found in all elementary text-books of algebra. It must suffice to notice here a few of the leading general properties of equations. By the roots of an equation are meant those values real or imaginary of the unknown which satisfy the equality; and it is a property of every equation to have as many roots and no more as there are units in its degree. Thus, a quadratic equation has two roots; a cubic equation, three; and a biquadratic, four. The quadratic equation $x^2 + 5x - 36 = 0$ has two roots, $+9$ and -4 , which will be found to satisfy it. Further, the expression $x^2 + 5x - 36 = (x - 9)(x + 4) = 0$; and generally if the roots of an equation

$$F(x) = x^n \pm A_{n-1}x^{n-1} \pm A_{n-2}x^{n-2} \pm \dots \\ \pm A_1x \pm A_0 = 0$$

(to which general form every equation of the n th degree can be reduced), are

$$\begin{aligned} & \pm a_1 \pm a_2 \pm a_3 \dots \pm a_n \dots \\ \text{then} \quad & (x \mp a_1)(x \mp a_2)(x \mp a_3) \dots \\ & (x \mp a_n) = F(x) = 0. \end{aligned}$$

Hence, and from observing the way in which, in the multiplication of these factors, the co-efficients

$$A_{n-1}, A_{n-2} \dots A_1, A^0$$

are formed, we arrive at the following important results:

A_{n-1} = the sum of the roots, with their signs changed.

A_{n-2} = the sum of the products of every two roots, with their signs changed.

A_{n-3} = the sum of the products of every three roots, with their signs changed.

A_0 = the product of the roots, with their signs changed.

The factors, it will be observed, are formed thus: If $+a_1$ be a root, then $x = a_1$, and $x - a_1 = 0$ is the factor. If the root were $-a_1$, then $x = -a_1$; and the factor would be $x + a_1 = 0$. Observing now the way in which, in multiplying a series of such factors, the co-efficients of the resulting polynomial are formed, we arrive at this: that a complete equation cannot have a greater number of positive roots than these *changes* of sign from $+$ to $-$ and from $-$ to $+$ in the series of terms forming its first member; and that it cannot have a greater number of negative roots than there are *permanencies* or repetitions of the same sign in proceeding from term to term. From the same source, many other general properties of E., of value in their arithmetical solution, may be inferred. The subject is, however, too vast to be more than glanced at here.

EQUATION OF TIME. It will be seen from the article EQUATION OF THE CENTER (q.v.) that the earth's motion in the ecliptic—or what is the same thing, the sun's apparent motion in longitude—is not uniform. This want of uniformity would of itself obviously cause an irregularity in the time of the sun's coming to the meridian on successive days; but besides this want of uniformity in the sun's apparent motion in the ecliptic, there is another cause of inequality in the time of its coming on the meridian—

viz., the obliquity of the ecliptic to the equinoctial. Even if the sun moved in the equinoctial, there would be an inequality in this respect, owing to its want of uniform motion; and even if it moved uniformly in the ecliptic, there would be such an inequality, owing to the obliquity of its orbit to the equinoctial. These two independent causes conjointly produce the inequality in the time of its appearance on the meridian, the correction for which is the equation of time.

When the sun's center comes to the meridian, it is apparent noon, and if it moved uniformly on the equinoctial, this would always coincide with *mean noon*, or 12 o'clock on a good solar clock. But from the causes above explained, mean and apparent noon differ, the latter taking place sometimes as much as $16\frac{1}{2}$ minutes before the former, and at others as much as $14\frac{1}{2}$ minutes after. The difference for any day, called, as we have said, the equation of time, is to be found inserted in ephemerides for every day of the year. It is nothing or zero at four different times in the year, at which the whole mean and unequal motions exactly agree—viz., about the 15th of April, the 15th of June, the 31st Aug., and the 24th December. At all other times, the sun is either too fast or too slow for clock-time. In the ephemerides above referred to, the sign + or — is prefixed to the equation of time, according as it is to be added to or subtracted from the apparent time to give the mean time. See NAUTICAL ALMANAC.

EQUATOR, CELESTIAL, is the great circle in the sky corresponding to the extension of the equator of the earth.

EQUATOR, TERRESTRIAL, the great circle on the earth's surface dividing the earth into the northern and southern hemispheres, and half way between the poles.

EQUATORIAL, an important astronomical instrument, by which a celestial body may be observed at any point of its diurnal course. It consists of a telescope attached to a graduated circle, called the declination circle, whose axis penetrates at right angles that of another graduated circle called the hour circle, and is wholly supported by it. The pierced axis, which is called the principal axis of the instrument, turns on fixed supports; it is pointed to the pole of the heavens, and the hour circle is of course parallel to the equinoctial. In this position, it is easy to see that a great circle of the heavens corresponding to the declination circle, passes through the pole, and is an hour circle of the heavens. The telescope is capable of being moved in the plane of the declination circle. If, now, the instrument be so adjusted that the index of the declination circle must point to zero when an equatorial star is in the center of the field of view of the telescope, and the index of the hour circle must point to zero when the telescope is in the meridian of the place, it is clear that when the telescope is directed to any star, the index of the declination circle will mark the declination of the star; and that on the other circle its right ascension. If the telescope be clamped when directed on a star, it is clear that, should the instrument be made to rotate on its principal axis with entire uniformity with the diurnal motion of the heavens, the star would always appear in the field of view. This motion of rotation is communicated to the instrument by clock-work. See *illus.*, CIRCLE, ETC., vol. III.

EQUERRY, in the household of the English sovereigns, is an officer of state under the Master of the Horse, whose principal function is to accompany the sovereign when riding in state. There are equerries also in attendance upon the royal princes.

EQUESTRIANISM. See HORSEMANSHIP.

EQUESTRIAN ORDER, or *EQUITES*. This body originally formed the cavalry of the Roman army, and is said to have been instituted by Romulus, who selected from the three principal Roman tribes 300 equites. This number was afterwards gradually increased to 3,600, who were partly of patrician and partly of plebeian rank, and required to possess a certain amount of property. Each of these equites received a horse from the state; but about 403 B.C., a new body of equites began to make their appearance, who were obliged to furnish a horse at their own expense. These were probably wealthy *novi homines*, men of equestrian fortune, but not descended from the old equites (for it should be observed that the equestrian dignity was hereditary). Until 123 B.C., the equites were exclusively a military body; but in that year Caius Gracchus carried a measure, by which all the *judices* had to be selected from them. Now, for the first time, they became a distinct order or class in the state, and were called *ordo equestris*. In 70 B.C., Sulla deprived them of this privilege; but their power did not decrease, as the forming of the public revenues appears to have fallen into their hands. After the conspiracy of Catiline, the E. O., which on that memorable occasion had vigorously supported the consul Cicero, began to be looked upon as a third estate in the republic; and to the title of *senatus populusque Romanus* was added *et equestris ordo*.

EQUESTRIAN STATUE, the representation of a man on horseback. Equestrian statues were awarded as a high honor to military commanders and persons of distinction in Rome, and latterly were, for the most part, restricted to the emperors, the most famous in existence being that of the emperor Marcus Aurelius, which now stands in the piazza of the capitol at Rome. It is the only ancient E. S. in bronze that has been preserved; an exemption which it probably owed to the fact, that for centuries it was supposed to

be a statue of Constantine. The action of the horse is so fine, and the air of motion so successfully given to it, that Michael Angelo is said to have called out to it "*Cammina!*"—(Go on, then!). It was originally gilt, and traces of the gilding are still visible on the horse's head. So highly is this statue prized, not only for its artistic but its historical value, that an officer used regularly to be appointed by the Roman government to take care of it, under the designation of the *custode del cavallo*. On the occasion of the rejoicings by which Rienzi's elevation to the tribuneship was celebrated in 1347, wine was made to run out of one nostril and water out of the other of this famous horse. The statue then stood in front of the church of St. John Lateran, near to which it was found, and a bunch of flowers has always been presented annually to the chapter of that basilica, in acknowledgment of ownership, since it was removed to its present site on the capitol. All European capitals are adorned, or disfigured, by numerous equestrian statues, London belonging pre-eminently to the latter category.

EQUIANGULAR, having equal angles. A figure is said to be E. all whose angles are equal to one number, as a square, or any regular polygon. All triangles and other figures are said to be E. one with another whose corresponding angles are equal.

EQUIDÆ, or **SOLIDUNGULA** (Lat. solid-hoofed), a family of mammalia of the order *pachydermata*, containing only a small number of species, which so nearly resemble each other that almost all naturalists agree in referring them to one genus, *equus*. They are distinguished from all other quadrupeds by the complete consolidation of the bones of the toes, or the extraordinary development of one toe alone in each foot, with only one set of phalangeal and of metacarpal or metatarsal bones, and the extremity covered by a single undivided hoof. There are, however, two small protuberances (*splint bones*) on each side of the metacarpal or metatarsal bone (*canon* or *cannon bone*), which represent other toes. The E. have six incisors in each jaw, and six molars on each side in each jaw; the males have also two small canine teeth in the upper jaw, sometimes in both jaws, which are almost always wanting in the females. The molars of the E. have square crowns, and are marked by laminae of enamel with ridges forming four crescents. There is a wide space between the canine teeth and the molars. The stomach of the E. is simple, but the intestines are long, and the cæcum extremely large; the digestive organs being thus very different from those of the ruminants, but exhibiting an equally perfect adaptation to the same kind of not easily assimilated food. Another distinctive peculiarity of the E. is, that the females have two teats situated on the pubes, between the thighs. But notwithstanding these characters, so dissimilar to those of the ruminants, they approach them very much in their general conformation, and may be regarded as a connecting link between pachyderms and ruminants. The largely developed and flexible upper lip is a character which belongs to the former rather than to the latter order.

The E. are now found in a truly wild state only in Asia and Africa. Fossil remains exist in the newer geological formations in great abundance in many parts of the old world; very sparingly, however, in the new, although the bones of a peculiar and distinct species (*equus curvidens*), belonging to the pleiocene period, have been found in South America.

The horse and the ass are by far the most important species of this family. The dziggethai has also been domesticated and made useful to man. Of the other species, the zebra, quagga, and dauw, it is generally believed that they are incapable of useful domestication.

EQUILATERAL, having equal sides. A square is equilateral. The equilateral hyperbola is that whose axes and conjugate diameters are equal.

EQUILIBRIUM, the state of rest or balance of a body or system, solid or fluid, acted upon by various forces. See **STATICS** and **HYDROSTATICS**.

EQUINIA, or **GLANDERS**. In another part of this work, glanders has been considered simply as a disease peculiar to animals, and especially the horse. We shall here consider it as a disease affecting man, to whom it is transmissible from animals.

In the great majority of cases, the disease is transmitted from the horse, the ass, or the mule to man; but several instances have been recorded in which it has been transmitted from one human being to another. The disease is no doubt generally due to inoculation, but the virus is also probably capable of being absorbed by unbroken mucous membrane. Most of the recorded cases have occurred in men of good constitution and in the prime of life. The four varieties of this disease which occur in the horse have also been observed in man—viz., (1) acute glanders, (2) chronic glanders, (3) acute farcy, and (4) chronic farcy.

Acute glanders is the commonest form. The period of inoculation ranges, in the majority of cases, from three days to a week. If there is a distinct wound or abrasion through which the poison has been absorbed, the parts around the broken surface become red, tense, and painful, often before the appearance of any of the constitutional symptoms, such as a general feeling of illness, great depression of the spirits, headache, rigors, increased rapidity of the pulse, and pain in the joints. A characteristic pustular eruption, often accompanied by bullæ or blebs, appears on the face and limbs; and

abscesses frequently occur on the face and about the principal joints. A yellow, purulent, fetid discharge, often mixed with blood, exudes from the nasal mucous membrane, which is invariably the seat of a pustular eruption, or of ulcerations. The prostration which is observable from the beginning increases during the course of the disease. The pulse becomes weak and frequent, the breathing difficult, the voice feeble, and the bowels very relaxed, the stools being extremely fetid. Delirium now sets in, which is followed by coma and death. Death usually occurs about the end of the second week, but the duration of the disease has been known to vary from three to fifty-nine days.—*Chronic glanders* is so rare an affection in man that it hardly requires notice. The course of the disease usually extends over several months; and only one case of recovery is reported.—*Acute farcy* seems only to differ essentially from acute glanders in the fact of there being no affection in the mucous membrane of the nostrils.

Little need be said regarding treatment, since no remedies have been found to exercise any influence in checking the course of acute glanders. Arsenic, combined with strychnia, has been found useful in chronic glanders in the horse, and is recommended by some practitioners as worthy of trial in man; and some relief might probably be afforded by the application of weak injections of carbolic acid into the nostrils.

EQUINOCTIAL is the same with the celestial equator. See **EQUATOR**, **CELESTIAL**. The **E.** points are those in which the **E.** and the ecliptic intersect. See **ECLIPTIC**. **E.** time is time reckoned from the moment when the point of Aries passes the vernal equinox. See **EQUINOXES**. This instant is selected as a convenient central point of a uniform reckoning of time for the purposes of astronomical observers.

EQUINOCTIAL STORMS, the winds which are believed to be prevalent at the time when the sun, in consequence of his proper motion, passes through the equinoctial points. The belief in the occurrence of such storms is widely spread, not only in this country, but also in Great Britain. The popular belief, however, seems to be unsupported by the records of carefully conducted observations. On the contrary, at Gordon Castle, in Strathspey, Scotland, observations conducted for nearly fifty years show fewer storms on the five days from the twenty-first to the twenty-fifth of March and September than on the five days preceding and the five days following these dates. Long-continued observations at other places in Great Britain are equally decisive against the popular belief. The whole question has been carefully investigated by Prof. R. H. Scott, of London. He collected all the data of severe storms that passed over Great Britain during a period of fourteen years, and found that out of forty-five storms occurring in March, not one occurred on the twenty-first, and of eighteen storms in September, only one occurred on the twenty-first. Taking intervals of three days and five days, he found :

| MONTHS. | THREE DAYS. | | | FIVE DAYS. | | |
|----------------|-------------|-------|-------|------------|-------|-------|
| | 17-19 | 20-22 | 23-25 | 14-18 | 19-23 | 24-28 |
| March..... | 5 | 3 | 2 | 8 | 5 | 4 |
| September..... | 1 | 2 | 2 | 3 | 2 | 6 |
| Total | 6 | 5 | 4 | 11 | 7 | 10 |

These figures show very plainly, especially in the five-day intervals, that storms are much more frequent just before and after the equinoxes than at the equinoxes themselves. This whole discussion will be found in the *Quarterly Journal of the Royal Meteorological Society of England* (1884).

With a view to determining the facts in regard to this subject, the Signal Office of the United States conducted very extensive investigations, working up all the observations of wind, pressure, rainfall, and storms recorded at nine different stations during the years 1873-88. In a report published in Nov., 1889, the result of these investigations is summed up thus: "The conclusion is inevitable, that the observations do not show a preponderance of storm action during the equinoxes." See *Monthly Weather Review* for Nov., 1889.

EQUINOXES. Sometimes the equinoctial points (see **EQUINOCTIAL**) are called the equinoxes. More commonly, by the equinoxes are meant the times when the sun enters those points, viz., 21st Mar. and 22d Sept., the former being called the vernal or spring equinox, and the latter the autumnal. When in the **E.**, the sun, through the earth's rotation on its axis, seems to describe the circle of the equator in the heavens, and the days and nights are of equal length all over the world. At the vernal equinox, the sun is passing from s. to n., and in the northern hemisphere the days are lengthening; at the autumnal, he is passing from n. to s., and the days are shortening. As the earth moves more rapidly when near the sun, or in winter, the sun's apparent motion is not uniform, and it happens that he takes eight days more to pass from the vernal to the autumnal equinox, than from the latter to the former. The equinoctial points are not stationary. See **ECLIPTIC**.

EQUIPMENT—EQUIPAGE, in military matters, are names given to certain of the necessities for officers and soldiers. During the Crimean war, many officers applied for and obtained money as compensation for the loss or injury of their E., comprising horses, horse appointments, baggage, saddlery, and accouterments. Equipments issued to private soldiers are expected to last a certain number of years, and small deductions from their pay are made in the event of the articles not lasting the proper time.

EQUIPMENT AND RECRUITING, BUREAU OF, a department in the U. S. navy, having charge of supplying vessels with rigging, sail, anchors, and all stock necessary for a voyage; also, the managing of the enlistment of seamen and boys, and of the recruiting service generally.

EQUIPOLLENT (Latin), equal in power or force, equivalent. In logic, propositions of like value in substance, though differing in expression. Example, "Immortality is the continued existence of the human soul in a future and invisible state." "The 'vital spark of heavenly flame' which exists beyond the limits of the grave is immortal."

EQUISETUM, a genus of cryptogamous plants, the structure and affinities of which are not yet well understood, but which many botanists regard as constituting a sub-order of ferns, whilst others prefer to make it a distinct order, *equisetaceæ*. The English name **HORSE-TAIL** is often given to all the species. They have a leafless, cylindrical, hollow, and jointed stem, each joint terminating in a membranous and toothed sheath, which incloses the base of the one above it. The fructification is at the summit of the stem in spikes, which somewhat resembles trobiles (cones), and are formed of scales bearing spore-cases on their lower surface. The spores are minute, oval, or round, green, and each accompanied with four elastic and hygrometrical threads. These threads are sometimes called *elaters*, but it is by no means certain that they are of the same nature with the spiral filaments so called, which are mixed with the spores of many *hepaticæ* (q.v.). Each thread terminates in a kind of club. The stems generally have lateral branches, angular, but otherwise similar in structure to the stem, growing in whorls from the joints; sometimes the stem is simple; or fertile stems are simple, and sterile stems are branched. The species of this genus contain a peculiar acid, called *equisetie acid*. Astringent and diuretic properties exist in these plants, and they were formerly used in medicine, but are not now regarded as of much value. It has been said that they are very injurious to cattle which eat them, but this seems to require confirmation. They abound chiefly in damp soils, and sometimes so much that the plow and harrow, or the grubber, must be employed to extirpate them. Some of them, however, grow in dry fields and gardens; whilst others are found chiefly in ditches or the banks of rivers. They exist in almost all parts of the world, and are seldom of large size, varying from a few inches to a few feet in height, but a comparatively gigantic species has recently been discovered in tropical America. The rough siliceous stems of some species are used for smoothing and polishing wood, particularly those of *E. hyemale*, which are imported into Britain in considerable quantities from Holland, under the name of **DUTCH RUSHES**. The stems of this species are unbranched, or a little branched only at the base. It is one of the most common species in the United States, although not indigenous, and is used for scouring, as in Europe. Other common species introduced from Europe are the scouring rush or shave grass (*E. arvense*), which is widely distributed; *E. sylvaticum* and *E. volutum*, with stems from three to six feet high, occur along river banks from Ohio to Illinois and southward. See *illus.*, **LYCOPODIACEÆ**, vol. IX.; **MUSCHELKALK PERIOD**, vol. X.

EQUITABLE DEFENSES. Under the old practice, by which the limits of common law and equity jurisdiction were strictly defined, equitable defenses were those which, though not competent in a court of common law, might be urged and recognized in a court of equity. As early as 1854 in England it was enacted that such defenses might in many cases be plead in a court of common law, and such pleading did not debar the defendant from afterwards applying for relief to a court of equity. The same permission is given by the codes and procedure acts in most of the American states. It may be stated that with very few exceptions what were formerly equitable defenses may now be put forward both in the United States and in England in the same action and simultaneously with what were formerly considered strictly legal defenses.

EQUITABLE ESTATES, originally estates in real property of such a character that courts of equity only would recognize their existence and effect. But under the fusion of law and equity practice since 1875 in England, and under the general code practice in the United States, as well as under the provisions of special statutes of other states, equitable estates are now recognized by courts not distinctly courts of equity. The most important classes of these estates are, equities of redemption, constructive trusts, the right of the *cestui que* trust in a trust estate, and equitable charges generally. Even under the old rigid distinction between law and equity a court of law might in some cases recognize the existence of an equitable estate; thus, a trustee guilty of breach of trust toward those possessing an equitable estate in the property might be criminally prosecuted in a court of law.

EQUITABLE MORTGAGE, either the mortgage of an equitable as distinguished from a legal interest in an estate (see **EQUITABLE ESTATES**) or a lien upon real estate not so

formally constituted as to be regarded by the common law as a mortgage, but recognized in equity as having practically the force of a mortgage. An example of the latter use of the phrase is to denote the lien existing where a debtor deposits his title deeds with a creditor. An American writer of authority mentions the following cases as coming properly under the designation of equitable mortgage: where the subject of the mortgage is trust property; where it is an equity of redemption; where there is merely a written agreement to make a mortgage; and the case of deposit of title deeds by a debtor, as above.

EQUITES. See EQUESTRIAN ORDER.

EQUITY, COURTS OF. The existence side by side of two completely distinct sets of courts, one administering common law and the other equity principles, was for centuries an anomaly in jurisprudence. In our times this anomaly has been in great measure done away with, both in the United States and in England; in the former country by procedure and code acts, in the latter by the effect of the statutes of 1875, which created one superior court having both common-law and equity jurisdiction in its four great divisions. In the United States many of the states have, from the beginning of their individual history, given to the same courts equity and law jurisdiction; others have, at a later period in their history, adopted what is known as the code practice, in which a single and simple form of procedure is followed and the old distinctions between law and equity are ignored. As an example, we may take the state of New York. Here separate equity courts long existed and the title of chancellor was retained up to 1814. The court of chancery, however, was cumbersome in its rules, uncertain in its principles, and generally disadvantageous. At that date Chancellor Kent began to unify and simplify its practice, and on the retirement, nine years later, of this great jurist the bar of New York in an address to him compared him to Lord Nottingham, of whom Blackstone said that "he was able in nine years to build up a system of jurisprudence and jurisdiction upon wise and national foundations," thus being really the founder of the equity system of England. But in 1848 New York abandoned the cumbersome double system of courts of equity and law and her practice is now single and simple, any court having power to apply the principles of equity as well as of the common law and statute law. The constitution of the United States especially confers equity powers upon United States courts. In a few states—chiefly or altogether in the south—the old distinction is still maintained. Of the principles of equity proper we speak in the following article. The history of the way in which separate courts of equity took their rise will be found sketched under the title **CHANCELLOR**. The remedies applied by courts of equity—whether separate or co-ordinate with common-law courts—are either designed to prevent wrong-doing, such as injunctions (which may be either prohibitory or mandatory), or to give relief for an injury already inflicted. Among the more important subjects to which courts will apply the latter class of remedies are: the relief from fraud or oppression in contracts; the compelling specific performance of contracts; the setting aside of contracts which are against public policy; the construing of contracts with a view to justice when the common-law rules would do injustice; the protecting of the equitable rights of a mortgagee; the appointing of receivers; the compelling disclosure of facts; the adjustment of partnership accounts; the relieving from the results of mistake or accident where common law would not intervene. All these and similar remedies, which were formerly ignored by courts of common law and could be obtained only by applying to a court of equity, can now be petitioned for and obtained in most of the states in this country and in England by petitioning to any court of original jurisdiction. Consequently, the old distinction which was made between the powers of courts of equity as being exclusive, concurrent or assistant, has now little importance.

Law and equity are generally now administered concurrently, and where the principles of the two great branches of jurisprudence differ, those of equity prevail. Certain classes of cases which were formerly the exclusive care of courts of equity (for instance, those relating to the rights of minors, as to person and property, to guardianship, trusts, etc.) have been handed over to the exclusive jurisdiction, in England, of the chancery division of the high court of justice; in the United States, in part to probate or—as they are called in some states—ordinary courts.

EQUITY, PRINCIPLES OF. In its use to denote a branch of jurisprudence, the word equity has a much narrower meaning than in its common use to signify simply natural justice. Equity came into existence to supplement the common law, not to supplant it. Its principles, at first, perhaps, indefinite and dependent in no small measure on the sense of justice of the chancellor or judge of an equity court, in time came to be recognized and determinate, limited in application and dependent on precedent in much the same way as were common-law principles. At first, indeed, the looseness in jurisdiction and in scope of principles was a cause of complaint among lawyers, so that one of them declared that "equity was only the length of the chancellor's foot." We may take as an illustration of the need of something to supplement common-law methods the common and important case of obtaining an injunction to prevent a wrong-doing. It was a maxim of the common law, "*ubi jus, ibi injuria*"—that is, wherever a legal right existed an injury thereto might be the subject of legal remedy; but this principle in nowise pro-

vided a remedy for a threatened injury. The obvious wrong in compelling a man to remain quiet when his property or personal interest were on the point of being attacked, to wait until the injury were completed, and then to be satisfied with money damages, suggested the important and practical remedy of calling upon a court to issue an order forbidding the carrying out of the wrongful purpose. This was quite contrary to common-law ideas, but was one of the first principles recognized by equity, and still continues to be one of the most important remedies granted by it.

We have said that equity had a narrower significance than natural justice ; it does not, accordingly, attempt to intervene to enforce justice in every conceivable case ; many matters must of necessity be left to the individual conscience and moral sense ; generally speaking, the principles of equity do not attempt to enforce "such moral duties as charity, gratitude, or kindness, or even positive engagements, which are not founded on a good or valuable consideration." This principle is well expressed by a decision in one of our state courts of appeal, which says that "Equity is not the chancellor's sense of moral right or his sense of what is equal and just, but is a complex system of established law ; and an equitable maxim—as, 'Equality is equity'—can only be applied according to established rules." In short, as is often said, equity is a portion of law accidentally severed from the common law. Although, as shown in the preceding article, the principles of equity and of common law are now almost universally, both in the United States and in England, administered by the same courts, yet it is often important to distinguish between them. The province of equity was rather to protect existing rights by keeping them intact, or by preventing foreseen injury to them, than to punish infraction of such rights or award damages after the wrongdoing. Its principles were accordingly applied more particularly to the granting of injunctions, the discovery of fraud, the correction of mistakes and accidents, the enforcing specific performance of contracts, the carrying out of trusts, the perpetuation of evidence, and similar matters. The principles of equity are illustrated and summarized in many maxims or formulae, such as : "Equity follows the law"—that is, a recognized rule of law will not be set aside by equity, but the effort will be to interpret or apply such a rule in a spirit of equity or natural justice ; "Equity looks to the substance and not to the form"—that is, in some cases (for instance, in mortgages of real estate) courts of equity will see that in the instrument which does not appear on its face—treating the mortgage, for instance, not as an absolute conveyance, but as a method of giving security for a loan, and protecting the right of the mortgagee after the debt is paid, or, as it is called, his equity of redemption ; "He who seeks equity must do equity"—that is, a person invoking principles of equity to his assistance must recognize those principles in his dealings with the other parties to the transaction ; "Equity assumes that to be done which ought to be done"—that is, a man may not, when demanding that principles of equity be applied to a transaction, at the same time rely on a mere technicality to establish his own right (following this principle equity will often, for example, treat an agreement to sell real estate as if a formal deed had been executed) ; "Where law and equity conflict equity prevails"—that is, a court of equity may sometimes overrule a court of law and even compel it to do what, under its own principles, it had refused ; and "Where there are equal equities, the law must prevail."

EQUITY OF REDEMPTION, the privilege retained by a mortgagee of real property to redeem the estate, although the original conditions of the mortgage bond have not been complied with. Under the wording of a mortgage it might be supposed that the mortgagee had absolute right of possession on the failure of the debtor to pay on the day named. Courts of equity, however, have regarded the property as being essentially a security, and have protected the rights of the mortgagee by giving him a reasonable time to redeem the property. This time, as well as the privilege itself, is often called the equity of redemption ; it varies in the states of this country from six months to several years. In common parlance the term is often used to denote the residue of value in a mortgaged piece of real estate which belongs to the mortgagee after deducting the amount of mortgage and interest due.

EQUIVALENTS, in chemistry. See **ATOMIC WEIGHTS**.

ERA. See **CHRONOLOGY**.

ÉRARD, SÉBASTIEN, 1752-1831; born in Strasburg ; distinguished for improvements upon the piano and the harp. He went to Paris, where the duchess of Villeroi became his patron, and in her house he made his first piano, which was one of the earliest manufactured in France. He became suddenly famous, and established a large manufactory in Paris, and during the revolution in London. Thenceforward devoting his life to the development and improvement of his favorite instrument, he brought it to a perfection before unknown.

ERA'SED AND **ERADICATED**, heraldically signifies that an object is plucked or torn off, and showing a ragged edge; as opposed to *coupé* or *coupy*, cut, which shows a smooth edge. A tree plucked up by the roots is said to be eradicated.

ERASIS TRATUS, one of the most famous physicians and anatomists of ancient times, flourished in the 3d c. B. C., and is supposed to have been born at Inlis, in the island of Ceos. He resided for some time at the court of Seleucus Nicator, king of Syria, and

while there acquired great renown by discovering and curing the disease of the king's eldest son, who was pining for the love of the young and beautiful Stratonice, whom his father in his old age had married. Afterwards E. lived for some time at Alexandria, where, giving up practice, he devoted himself with great energy and success to his anatomical studies. The date of his death, which seems to have taken place in Asia Minor, is not known. He founded a school of medicine, wrote several works on anatomy—in which branch he was most celebrated—on practical medicine, and pharmacy. He believed that the heart was the origin both of the veins and arteries, and, had it not been his conviction that the arteries contained *air* instead of *blood*, little doubt is entertained but that he would have anticipated Harvey in the discovery of the circulation of the blood. Of his numerous writings only some obscure fragments and titles have been preserved. Compare Hieronymus, *Erasistrati et Erasistrateorum Historia* (Jena, 1790).

ERASMUS, DESIDERIUS, one of the most vigorous promoters of the reformation, was b. at Rotterdam, 28th Oct., 1467. He was the illegitimate son of a Dutchman named Gheraerd, or Garrit, by the daughter of a physician. In accordance with the fashion among scholars of his time, he changed the name Gheraerd into its Latin and Greek equivalents Desiderius Erasmus (more correctly Erasmus)—meaning desired, loved. Till his 9th year, E. was a chorister in the cathedral at Utrecht. He was then sent to school at Deventer, where his talents began to display themselves in so brilliant a manner, that it was even then predicted that he would one day be the most learned man of his time. After the death of his parents, whom he lost at the age of 14, his guardians determined on bringing him up to a religious life, and—with the intention, it is said, of sharing his small patrimony among themselves—in his 17th year, placed him in the Augustinian convent of Stein. From this constrained manner of life, however, he was released by the bishop of Cambray. After having taken priest's orders he went to Paris (in 1496), to perfect himself in theology and the humane sciences. Here he supported himself in a somewhat precarious manner, by giving private lectures, and in 1497 accompanied some Englishmen, who had been his pupils, to England, where he was well received by the king. He, however, soon returned to Paris, and in 1506, to enrich his knowledge, visited Italy. At Turin he took the degree of D.D. Shortly after, he applied to the pope for a dispensation from his monastic vows, granted in 1516. During the course of his journey he visited Venice, Parma, Rome, and other interesting cities, in company with his pupil, Alexander Stuart, a natural son of James IV. of Scotland, who, along with his father, was afterwards slain at the battle of Flodden. At Rome, the most brilliant prospects were held out to him. Cardinal Grimani, a famous lover of learning in that day, offered, out of his admiration for E., to make him "partaker of his house and fortunes." Other eminent men vied with Grimani in showing respect to the young scholar, among whom may be mentioned John de' Medici, afterwards Leo X., cardinal Raphael of St. George, and Giles of Viterbo, gen. of the Augustines. The pope (Julius II.) also offered him a place among his penitentiaries, an office of considerable consequence, and, it would appear, a "step to the highest preferments in that court." E., who had always an eye to the main chance, regretted, at a later period of his life, that he had not accepted the offers held out to him in Rome, but meanwhile, having pledged himself to return to England, where also he had many friends, he set out for that country in 1509, after the accession of Henry VIII. In several of the cities through which he passed he met with friends and patrons, who wished him to settle amongst them, but as Henry was a correspondent of his, E. was induced to cherish the highest hopes of personal favor from that monarch, and could not be prevailed on to stay for more than a very brief period. He had no sooner, however, arrived in England than he found out his mistake. At first, he lodged with sir Thomas More, and during his stay with him composed his *Encomium Morie*, or Praise of Folly, the purpose of which is to expose all kinds of fools, but especially those who flourished in the church, not sparing the pope himself. For a short time he filled the office of professor of Greek at Oxford, but on the whole was very scantily supplied with the means of subsistence. In 1514, he returned disappointed to the continent, and resided chiefly at Basel, where he died, 12th July, 1536. E.'s extensive and profound learning was equalled by his refined taste and brilliant wit. A natural love of independence and quiet made him prefer a life of learned leisure and retirement to one of greater publicity, nevertheless, the readiness with which he assumed the character of an adroit man of the world, brought upon him the hostility of many of the nobler spirits of his time. He was no hero, and he knew it. He frankly confesses that "he had no inclination to die for the sake of the truth." Luther, in whom the soul and courage of the apostle Paul seemed to be revived, overwhelmed him with reproaches for his cowardice in regard to the reformation. But we must not forget that E. by his mental constitution was averse to enthusiasm. He was a scholar and a critic, not a preacher or iconoclast, and he was at least honest enough to abstain from denouncing the opinions of Luther, though he disapproved strongly of his violent language. Besides, there was a tincture of rationalism in the great Dutchman, which probably helped to chill his love of mere *Lutheranism*. But his services in the cause of science were great and lasting, and his writings are still esteemed for the importance of the subjects treated of, and their classical style. Besides editing several of the ancient authors, and various philological and theological writings, he prepared the earliest edition of the Greek Testament, which

appeared at Basel in 1516. This is reckoned by some his greatest work. Michaelis says that perhaps there never existed an abler editor of the New Testament, and that E. possessed in the highest degree natural abilities, profound learning, a readiness in detecting errors, with every qualification that is requisite to produce critical sagacity. His best known work, however, is his *Colloquia*, a masterpiece. Of all his writings, this has exercised the greatest influence. The first edition appeared in 1522, but did not please E., who issued a second during the same year. A third appeared in 1524. This book, which was meant, according to Erasmus, only to make youths better Latinists and better men, was condemned by the Sorbonne, prohibited in France, and burned in Spain. No one who takes up the book will wonder at its condemnation. It contains the most virulent and satirical onslaughts on monks, cloister-life, festivals, pilgrimages, etc., but it is disfigured by lewd and unchaste passages, which are wholly inexcusable. The work has been translated into almost all the modern languages. His *Encomium Morie*, or Praise of Folly, has been already mentioned. It was published in the original, with a German translation, and illustrations by Holbein, by W. G. Becker (Basel, 1780). E. himself superintended an edition of his works, published by Frobenius in Basel. The most complete edition is that of Leclerc (10 vols., Leyden, 1603-6). The life of E. has been written in French by Burigny (2 vols., Paris, 1758), in German by Müller (Hamburg, 1823), and in English by Knight (Cambridge, 1726), Drummond (2 vols., 1873), and Froude (1894).

ERASTIANS (see ERASTUS, THOMAS) were adherents of the doctrines laid down by Erastus in his book on *Excommunication*, namely, that though the spiritual part of religion is entirely a matter of individual opinion and inclination, its external organization, such as the nomination and commission of ministers, the punishment of moral offenses, etc., is entirely a matter of civil government; and that, consequently, the church can have no right under any circumstances to communicate or withhold its privileges from any of its members. There never was an actual sect of E. in Great Britain, but these views were speedily adopted by various eminent Englishmen and were upheld in the Westminster assembly, 1643-49, by the eloquence of the lawyers Selden, St. John, and Whitelocke, and the divines Lightfoot and Coleman. But, after a long controversy, the proposition that "the Lord Jesus, as king and head of His church hath, therein appointed a government in the hand of church officers, distinct from the civil magistrate" was finally carried, against the single dissentient vote of Lightfoot. Though the *Chapter of Church Censure* in which it occurs was never formally ratified by Parliament, Erastianism failed from that time to take any deep root. During the conflict in the church of Scotland, which resulted in the secession of the Free church, the term Erastian was constantly applied to all who held that the church had no power to nullify by law the operation of lay patronage; but it was indignantly rejected by them. It is now often used, but with little knowledge of its real meaning, by the extreme Presbyterians as a term of reproach against the more moderate party.

ERASTUS, THOMAS, a learned physician and theologian, was b. at Baden in Switzerland, 7th Sept., 1524. His real name was *Lieber*, which, according to the fashion of his times, he translated into Greek. In 1540, he went to the university of Basel, where he studied divinity, philosophy, and literature. He subsequently visited Italy, where he betook himself to medicine, and obtained the degree of M.D. from the university of Bologna. After an absence of nine years, he returned to his own country, and lived for some time at the court of the princes of Henneberg, where he acquired a great reputation as a medical practitioner. The elector palatine, Frederick III., now invited him to his court, and appointed him first physician and counselor of state. He also conferred on him the chair of physic in the university of Heidelberg. In 1581, he was selected to fill a similar office at Basel, where he died, Dec. 31, 1583, after establishing a liberal foundation for the provision and education of poor students in medicine, which was long called the *Erastian foundation*. Among E.'s medical works may be mentioned his *Disputationum de Medicina Nova Philippi Paracelsi* (Basel, 1572-73); *Theses de Contagio* (Heidelberg, 1574); and *De Occult. Pharmaco. Potestativibus* (Heidelberg, 1574). As a physician, E. is creditably characterized by his distrust of abstract and *a priori* theorizing, and his conviction that experimental investigation is the only road to knowledge. But his fame now rests chiefly on what he wrote in ecclesiastical controversy. In his book *De Cæna Domini*, he contended for the figurative interpretation of the passage, "This is my body," etc., and supported this view at the conference held at Maulbronn between the divines of the palatinate and those of Wittenberg. But his great work is his *Eeplatio Questionis Gravissimæ de Excommunicatione*. Although this work was not published till some years after his death, E. had published the same opinions as it contains in the form of theses, directed against Gaspar Olevianus, a refugee from Treves, and various other persons, who were anxious to confer on ecclesiastical tribunals the power of punishing vices and misdemeanors. E. denied the right of the church to excommunicate, exclude, absolve, censure—in short, to exercise discipline. Denying "the power of the keys," he compared a pastor to a professor of any science, who can merely instruct his students; he held that the ordinances of the gospel should be open and free to all, and that penalties being both in their nature and effect *civil* and not *spiritual*, ought to be inflicted only by the civil magistrate.

E'RATH, a co. in central Texas, drained by Bosque river; 1042 sq.m.; pop. '90, 21,594, incl. colored. The surface is rolling and tolerably fertile, but best adapted to pasturage. Co. seat, Stephenville.

ERATO, one of the nine muses, daughters of Jupiter and Mnemosyne. She presided over amatory and nuptial poetry. See illus., MYTHOLOGY, vol. X.

ERATOS THENES, an eminent Greek writer, called, on account of his varied erudition, the *philologist*, was b. at Cyrene 273 B.C. Among his teachers were Lysanias the grammarian, and Callimachus the poet. By Ptolemy Euergetes, he was called to Alexandria to superintend his great library. Here he died of voluntary starvation, at the age of 80, having become blind, and wearied of life. As an astronomer, E. holds an eminent rank among ancient astronomers. He measured the obliquity of the ecliptic, and the result at which he arrived—viz., that it was $23^{\circ} 51' 20''$ —must be reckoned a very fair observation, considering the age in which he lived. Hipparchus used it, and so did the celebrated astronomer Ptolemy. An astronomical work which goes under the name of E., but which is certainly not his, is still extant, and is called *Katasterismoi*; it contains an account of the constellations, their fabulous history, and the stars in them. It is believed, however, that E. did draw up a catalogue of the fixed stars, amounting to 675; but it is lost. A letter to Ptolemy, king of Egypt, on the duplication of the cube, is the only complete writing of his that we possess. E.'s greatest claim to distinction, however, is as a geometer. In his attempt to measure the magnitude of the earth, he introduced the method which is used at the present day, and found the circumference of the earth to be 252,000 stadia; which, according to Pliny, is 31,500 Roman miles. But as it is not known *what* stadium E. used, it is possible that he came nearer the actual circumference than the above figures indicate. His work on geography must have been of great value in his times: it was the first truly scientific treatise on the subject. E. worked up into an organic whole the scattered information regarding places and countries related in the books of travels, etc., contained in the Alexandrian library. He also wrote on moral philosophy, history, grammar, etc. His work on the Old Attic Comedy appears, from the remains we possess, to have been a learned and very judicious performance. Such fragments of E.'s writings as are still extant have been collected by Bernhardt in his *Eratosthenica* (Berlin, 1822).

ERBIUM (symbol E) is a rare metal, the compounds of which are found in a few scarce minerals, especially in *gadolinite*, obtained from Ytterby, in Sweden. In its compounds and properties it resembles the metal aluminium.

ERCILLA Y ZUÑIGA, ALONSO, a Spanish poet, was b. at Madrid, Aug. 7, 1533. He was the third son of a Spanish jurist, and at an early period became page to the infanta Don Philip, son of Charles V., accompanying him on his journey through the Netherlands, and some parts of Germany and Italy, and, in 1554, to England, on the occasion of the celebration of Philip's nuptials with queen Mary. Shortly after, E. went with the army dispatched to America to quell the insurrection of the Auracians on the coast of Chili. The difficulties with which the Spaniards had to contend, the heroism displayed by the natives in the unequal contest, and the multitude of gallant achievements by which this war was distinguished, suggested to E. the idea of making it the subject of an epic poem. He began his poem on the spot, about the year 1558, occasionally committing his verses, in the absence of paper, to pieces of leather. An unfounded suspicion of his having plotted an insurrection involved him in a painful trial, and he had actually ascended the scaffold before his innocence was proved. Deeply wounded, the brave soldier and poet turned to Spain, but Philip treating him with coldness and neglect, E. made a tour through France, Italy, Germany, Bohemia, and Hungary. For some time he held the office of chamberlain to the emperor Rudolf II., but in 1580 returned to Madrid, where he in vain exerted himself to realize an independence. The latter years of his life were spent in obscurity and poverty at Madrid, where he died, 1594. His historic epos, written in the octosyllabic measure, and entitled *Araucana*, is, with the exception of a few episodes, a faithful description of actual events. Cervantes, in his *Don Quixote*, compares it with the best Italian epics, and it has undoubtedly not a little of the epic style and spirit. The first part is the freshest in character, having been completed before the author's return to Europe, where it was first published separately (Madrid, 1569). The second part appeared nine years later. In it E., by the introduction of episodes, yielded more to the taste of the time; and this was still more the case in the third part, which was first published, along with the two others, in 1590. In Spain, and likewise in other countries, many reprints of the poem appeared (the most elegant, 2 vols., Madrid, 1776; the most accurate, 2 vols., Madrid, 1828). A continuation was published by Don Diego Santistevan Osario, of Leon (Salamanca, 1597). A German translation has been published by Winterling (2 vols., Nuremberg, 1831).

ERCKMANN-CHATRIAN (EMILE ERCKMANN and ALEXANDRE CHATRIAN), two French men of letters, the first of whom was born 20th May, 1822, at Phalsbourg; the second, 18th Dec., 1826, in the village of Soldatenthal, commune of Abreschwiler, both in what was then the French dep. of Meurthe, but is now reunited to Germany as part of the imperial territory of Alsace-Lorraine. Erckmann, the son of a bookseller,

went through a rather irregular course of study at the college of his native town, went to Paris in 1842 to study law, which he broke off several times, and only passed his third examination in 1857, and finally abandoned the study in the following year. During the interval, he had set himself to make a name in literature, in co-operation with M. Chatrian. The latter, belonging to an old family of glass-makers in Meurthe, ruined by reverses in trade, was acting as tutor at the college of Phalsbourg, when, in 1847, he was introduced to M. Erckmann. From that time the two friends employed their pens in the same works, which they signed with the two names united in one; and it was only about 1863 that the authors informed their readers that the numerous works of fiction, which had obtained a wide-spread popularity, and were supposed by the general public to be the work of a single writer, were the fruits of their friendly collaboration. Their early works attracted comparatively little notice; and it is said that their first work was rejected by all the newspapers of Paris, and by many provincial journals. In 1848, they published several feuilletons in the *Démocrate du Rhin*, which had just been started: *Le Sacrifice d'Abraham*, *Le Bourgmestre en Bouteille*, etc., which they have since published separately. At the same time they wrote a drama, *Le Chasseur des Ruines*, for the Ambigu-Comique, which the theater accepted, subject to changes, which they refused to make. They produced another drama, *L'Alsace* in 1814, for the theater of Strasburg, which was suppressed by the prefect on the second representation. They wrote numerous novels at this time for different journals, some of which were very little noticed, while others remained in MS. for years. Despairing of being able to live by their pens, Erckmann recommenced his law studies, and Chatrian obtained a situation in the office of the Eastern railway. It was not till 1859 that *L'Illustre Docteur Mathéus* (1859, in-18; 3d edition, 1864), published by the Librairie-Nouvelle, gave a certain éclat to the collective name of Erckmann-Chatrian. *Le Fou Yégoïf* (1862, in-18) is one of a series of novels, the subjects of which are taken from their national history, and gives a picture of the invasion of 1814. *Le Conscrit de 1813* (1864) and *Waterloo* (1865) are fragments of an autobiography, and are supposed to be the recollections of a common soldier, and relate the disastrous campaigns of 1813 and 1814. These may be called the gems of their collection. *Le Joueur de Clarinette* (1863), a simple story of a village musician, and *Les Amoureux de Catherine*, another tale of village life in the same volume, are nearly perfect. *L'Homme du Peuple* appeared in 1865, and is less favorably spoken of as a work of art. It pictures the life of the modern French workman. In 1866, appeared *La Maison Forestière*, and *La Guerre*; in 1867, *Le Blocus*, which has been translated under the title, *The Blockade of Phalsbourg*; a historical romance in 1868, *Histoire d'un Paysan*; in 1869, *Le Juif Polonais*, a play. Among their latest works are *The Story of the Plébiscite by one of the 7,500,000 who voted Yes* (trans. in *Cornhill Magazine*, 1871-72); and *Brigadier Frédéric: a Story of an Alsatian Exile*; *Les Rantzeu* (1882). In 1888 the two friends quarreled, but were reconciled in the following year, and in 1890 Chatrian died. Erckmann subsequently published *Kaleb et Khora* and *La Première campagne du grand-père Jacques*. See COLLABORATION.

ERDMANN, JOHANN EDUARD, a German philosopher; b. 1805; studied theology at Dorpat, attended the lectures of Schleiermacher and Hegel, and became a pastor. In 1836, he was appointed professor of philosophy at Halle. He published a number of works, including *Grundriss der Geschichte der Philosophie* (1866, Eng. trans. 1893). He d. in 1892.

ERDMANN, OTTO LINNE, 1804-69; a German chemist, educated at Dresden and the university of Leipsic; professor of chemistry at Leipsic, where he established a model laboratory. He made important discoveries in the qualities of nickel, and of indigo and other dye-stuffs. He founded a journal devoted to chemical science, and published a number of works on the subject.

EREBUS—the name of one of the sons of Chaos—signifies darkness, and is used specially to denote the dark and gloomy cavern beneath the earth, through which the shades pass in going to Hades.

ERECHTHEUS or **ERICHTHONIUS**, and **ERECHTHE'UM**. Erechtheus, an Attic hero, is said to have been the son of Hephaestus and the earth, and to have been reared by Athena. One form of the tradition states that when a child he was placed by Athena in a chest, which was intrusted to Agrauios, Pandrosos, and Herse, the daughters of Cecrops, with the strict charge that it was not to be opened. Agrauios and Herse, however, unable to restrain their curiosity, opened the chest, and discovering a child entwined with serpents, they were seized with madness, and threw themselves down the most precipitous part of the Acropolis. Afterwards Erechtheus was the chief means of establishing the worship of Athena in Attica. He is regarded as the founder of the Erechtheum, the temple of Athena Polias, guardian of the city. This original Erechtheum, which contained Erechtheus's tomb after his death, and which was called by his name, was burned by the Persians, but a new and magnificent temple was raised upon the same site—n. of the Parthenon, and near the northern wall of the Acropolis—in the beginning of the 4th c. B.C. The second Erechtheum was a splendid structure of the Ionic order, of an oblong shape, extending from e. to w., abutting in side chambers at the western end, towards the n. and s., and having porticoes adorned with columns at its eastern, its northern, and southern extremities. It is now a complete ruin. See illus., GREECE, vol. VII.

ERECTION, LORDS OF, those of the nobility in Scotland to whom the king, after the reformation, granted lands, or tithes, which formerly belonged to the church. They were also called titulars of tithes; the gifts being by no means confined to the nobility. These titulars had the same rights to erected benefices, both in lands and tithes, which had formerly belonged to the monasteries and other religious houses. The grants were made under the burden of providing competent stipends to the reformed clergy—an obligation which was very little attended to by the grantees, prior to the decrees arbitral of Charles I., in 1629.

EREGLI, or **EREKLI** (anc. *Heraclea*), a t, and port in Asia Minor, on the Black sea, 128 m. e.n.e. of Constantinople; pop. 2,000. There is a good harbor, some ship-building, and export trade in timber, coal, silk, linen, wax, etc. The coal mines are extensive, and yield much of the supply of Constantinople. E. is the place where the 10,000 Greeks under Xenophon embarked on their return.—Another town of the same name, 55 m. n.w. of Constantinople, has a harbor on the sea of Marmora.

EREMACAUISIS (Gr. *ërema*, gently, and *kausi*, combustion) is a term originally proposed by Liebig to indicate the slow process of combustion at ordinary temperatures, which ensues when organic compounds, such as wood, are left exposed to the air, and gradually rot away or decay. The process consists in the oxygen (O) of the air combining with the hydrogen (H) of the wood forming water (HO), and in less quantity with the carbon (C) forming carbonic acid (CO₂), leaving a brown mold or powder, called by chemists ulmin, or humus, in which carbon preponderates.

ERETRIA, a city in the island of Eubœa, founded before the war of Troy, and anciently the rival of Chalcis in commerce. It was destroyed 490 B.C., by the Persians, but was soon rebuilt, and was active in the Peloponnesian war. It was the seat of the school of philosophy established by Menedemus, a disciple of Plato. The ruins of the city are still visible.

ERFURT, a city of Prussian Saxony, anciently capital of Thuringia, stands in a highly cultivated plain, on the right bank of the Gera, 14 m. w. of Weimar. Till 1873, E. was strongly fortified, and was accounted a fortress of the second rank. Its two citadels, the Petersberg and the Cyriaksburg, were both formerly monasteries. Among the numerous churches, the cathedral and the church of St. Severus are the finest. The cathedral is one of the most venerable Gothic buildings in Germany, and possesses, besides a very rich portal, sculptures dating from the 11th to the 16th century. Of the convents, only that of the Ursuline nuns remains. The monastery of St. Augustine, famous as the residence of Luther, whose cell was destroyed by fire in 1872, was converted in the year 1820 into an asylum for deserted children. The other remarkable buildings are the university, founded in 1378, and suppressed in 1816; the royal academy; the library; numerous educational establishments, infirmaries, etc. Pop. '71, 43,616; '95, 78,167. Horticulture and an extensive trade in seeds are carried on. The principal manufactures are woolen, silk, cotton, and linen goods, yarn, shoes, stockings, tobacco, leather, etc.

E. is said to have been founded in the beginning of the 5th c. by one Erpes, from whom it took its original name of Erpesford. During the middle ages, at the time of its highest prosperity, E. was strongly fortified, and contained 60,000 inhabitants. In 740, St. Boniface founded a bishopric at E., and in the year 805 it was converted into an entrepôt of commerce by Charlemagne. It afterwards belonged to the Hanse-league, then to the elector of Mainz, from 1801-6 to Prussia, and from that time until 1813 it was under French rule. E. was finally restored to Prussia by the congress of Vienna. In the spring of 1850, the parliament of the states, which had combined together for union, held its sittings at Erfurt.

ERGOT, a diseased condition of the germen of grasses, sometimes also observed in some of the *cyperaceæ*. It begins to show itself when the germen is young; different parts of the flower assume a mildewed appearance, and become covered with a white coating composed of a multitude of minute spore-like bodies mixed with delicate cob-web-like filaments; a sweet fluid, at first limpid, afterwards viscid and yellowish, is exuded; the anthers and stigmas become cemented together; the ovule swells till it greatly exceeds the size of the proper seed, bursts its integuments, and becomes elongated and frequently curved, often carries on its apex a cap formed of the agglutinated anthers and stigmas, and assumes a gray, brown, purple, violet, and at length a black color, as the viscid exudation dries and hardens. The structure differs very much from that of the properly developed seed; the qualities are not less different, almost one half of the whole substance consists of *fungin*; and the cells contain, instead of starch, globules of a peculiar fixed oil—**OIL OF ERGOT**, to which the remarkable qualities of E. are supposed to be chiefly or entirely due. Oil of E. forms about 35 per cent of the E. of rye. E. appears to have been first observed in rye, in which it becomes very conspicuous from the large size it attains, sometimes an inch or even an inch and a half in length. It is, however, not uncommon in wheat and barley, although in them it is not so conspicuous, from its general resemblance to the ordinary ripened grain. Rye-grass is often affected with E., as are many other grasses; and it is of frequent occurrence in maize, in which also it attains its greatest size. E. has been supposed to be merely a

disease occasioned by wet seasons or other climatic causes. But it appears now to be fully ascertained that it is a disease occasioned by the presence of the *mycelium* of a fungus; the spores of which may perhaps be carried to the flower through the juices of the plant, for there is reason to think that E. in a field of grain may be produced by infected seed. Mr. Quekett, in 1838, described a fungus, a kind of mould (q.v.), which he found in E., and to which he gave the name of *ergotetia abortifaciens*. Link and Berkeley afterwards referred it to the genus *oidium*; and they, as well as others, believed it to be the true E. fungus. The spores of this E. mold, however, vegetate readily, under proper conditions of warmth and moisture, in situations very different from that in which E. is produced; and its presence is perhaps a consequence rather than the cause of ergot. The true E. fungus seems to have been discovered by Tulasne, who published a description of it in 1853. That of the E. of rye is called *cordiceps* (or *claviceps*) *purpurea*; its mycelium alone exists in E., but if the ergoted grains are sown, the fungus develops itself in its perfect form, growing in little tufts from the surface of the E., with stem about half an inch long, and subglobular head. Allied species appear to produce the E. of other grasses.

E. is inflammable; the fixed oil which it contains, indeed, makes it burn readily if brought into contact with the flame of a candle. It is a valuable medicine, exercising a specific action on the womb, particularly during labor, and by the greater frequency and force of the contractions which it causes when cautiously administered, often most beneficially hastening delivery. Its employment for this purpose is said to have originated—in consequence, probably, of an accidental discovery—with a provincial female practitioner in France. Its introduction into American practice dates only from 1824. It is the E. of rye which is always employed; also called **SPURRED RYE**, or *secale cornutum*. It has been employed also as a sedative of the circulation, to check various kinds of hemorrhage. E. is administered in various forms—powder, decoction, extract, tincture, oil of E., etc.—In large or frequent doses, E. is a poison, sometimes producing convulsions, followed by death; sometimes gangrene of the extremities, resulting in mutilation or in death.

E. of rye consists of 35 per cent of a peculiar fixed oil, $1\frac{1}{4}$ of ergotin, 46 of fungin, the remainder being gum, fat, albumen, salts, etc. E. burns with a yellow-white flame, and treated with water, yields a reddish colored liquid with acid properties. In considerable quantities, it is a poison to the lower animals as well as to man.

ERGOTISM, the constitutional effect of ergot of rye (q.v.). See also **RAPHANIA**.

ERIC is the Scandinavian form of the name Henricus, Enrico, and Henry of southern nations. Many kings of the name reigned separately in Denmark and Sweden, and some ruled over the whole of Scandinavia after the union of Calmar. The memory of the two earliest rulers of the name in Denmark merits our notice from their association with the introduction of Christianity. Eric I., who died in 860, protected the Christians in the latter part of his reign, and, under the direction of the missionary Ansgar or Ansharius, founded the cathedral of Ribe, the first Christian church in the land. In his time, the Northmen began those incursions into more southern countries, which were destined to exercise so permanent an influence on European history. Eric II. followed in the steps of his father, and permitted Ansgar to prosecute the labor of converting and civilizing the people, which won for him the title of the tutelar saint of the north. To Eric II. is ascribed the reorganization of those guilds which finally merged in the municipal corporations of the middle ages, but which were, at first, a mere modification of the heathen brotherhoods of the Scandinavian heroic ages, and constituted associations, whose members were a privileged class, separated by distinct laws, rights, and duties from the rest of the people. Denmark suffered in the 12th c. in an equal degree from the two Erics who ruled over her, for while Eric, surnamed Emun, exhausted the strength of the land by the indomitable pertinacity with which he endeavored, by force of arms, to compel the Vandals and other piratical neighbors to accept the Christianity which he thrust upon them, Eric "the Lamb" crippled the powers and resources of the crown by his pusillanimous subserviency to the clergy. The three Erics (Eric VI., VII., and VIII.) who occupied the throne, with only the intermission of a few years, from 1241 to 1319, are associated with one of the most disastrous periods of Danish history. Long minorities, the suicidal practice of dismembering the crown-lands in favor of younger branches of the royal house, and futile attempts to restrain the ever-increasing encroachments of the church, combined to bring the country to the brink of destruction. Eric VI. (Plogpenning) and Eric VII. (Glipping) were both assassinated, the former at the instigation of a brother, and the latter in revenge for a private injury. Eric VIII., the last of the name before the union of Calmar, died childless, and was succeeded, in 1319, by his ambitious brother Christopher, who saw himself compelled to repay his partisans at the expense of almost all the prerogatives and appanages which still belonged to the crown.

In Sweden, the first of the name who merits our notice is king Eric, surnamed the Saint, who was slain in battle in 1161, after a short reign, which was signalized, in that age of anarchy, by the foundation of many churches and monasteries, and by the promulgation of an excellent code of laws, known as *St. Eric's Lag*. This law contained provisions by which a higher status in society was secured to women, by granting

them a fixed proportion of the heritage of their male relatives, and certain definite privileges within their households. St. Eric waged frequent war with the Finns, and compelled them to adopt the outward forms of Christianity. The two namesakes and descendants of St. Eric, who ruled in Sweden during the 13th c., and Eric XII., who reigned from 1350 to 1359, have little claim to our notice, for internal disturbances and wars with their neighbors brought about the same fatal results as those which are associated with the reigns of the *Eric*s in Denmark during the middle ages. In 1412, on the death of the great Margaret, her relative, Eric of Pomerania, succeeded to the triple crown of Scandinavia, in accordance with the articles of the famous treaty of Calmar. The noble heritage that had been bequeathed to Eric required a firmer hand and a braver spirit than his to keep it in check; and his reckless disregard of treaties and oaths, his neglect of his duties, and his misdirected ambition, led, after years of dissensions, maladministration, and disaffection, to the inevitable result that Eric was declared to have forfeited the respective thrones of the several kingdoms, which proceeded to elect rulers of their own. The intestine wars to which this condition of things gave rise, plunged the whole of Scandinavia into anarchy, and sowed seeds of dissension among the three kindred nations, which bore fatal fruits in subsequent ages. The last ten years of Eric's life were spent in the exercise of piracy in the island of Gothland, whither he had retired with his mistress and a band of followers, and from whence he sent forth piratical expeditions to pillage both friends and foes. Eric married Philippa, daughter of Henry IV. of England, whose memory is still cherished in the north, on account of the many noble deeds with which local tradition associates her name. Eric XIV., the last of the name who reigned in Sweden, had the distinction of being at once one of the worst and one of the most unhappy of the name. He succeeded, in 1560, to the throne of his father, Gustaf Vasa, who was perhaps the greatest and worthiest monarch that ever reigned over Sweden, and immediately on his accession, he made known the difference that was so unfavorably to distinguish his reign from that of his father, by quarrelling with his brothers, thwarting the nobles, and opposing the lower orders. His fickleness and extravagance were displayed in a succession of embassies, which were in turn sent to almost every European court to demand a consort for this vacillating monarch, who usually changed his mind before his envoys had time to fulfill their missions. Elizabeth of England and Mary of Scotland were more than once the objects of his matrimonial schemes; but when the resources of the country had been seriously crippled by these costly and absurd expeditions, Eric married a Swedish peasant-girl, who ultimately acquired an influence over him which was ascribed by the superstitious to witchcraft, since she alone was able to control him in the violent paroxysms of blind fury to which he was subject. It is probable that Eric labored under remittent attacks of insanity, and that to this cause may be attributed the bloodthirsty cruelty with which he persecuted those of his own relatives or attendants who fell under his suspicion. His capricious cruelties at length alienated the minds of his subjects, who, wearied with the continuous wars and disturbances in which his evil passions involved them, threw off their allegiance in 1568, and solemnly elected his brother John to the throne. For nine years, the unhappy Eric suffered every indignity at the hands of the keepers appointed by his brother to guard him, and in 1577, he was compelled to terminate his miserable existence by swallowing poison, in obedience to his brother's orders. Singular to say, this half madman was a person of cultivated understanding, and he solaced his captivity with music and the composition of psalms, and in keeping a voluminous journal.

ERIC THE RED, a native of Norway, b. about 950 A.D. He fled from Norway to escape punishment for homicide, and settled on the w. coast of Iceland. Another homicide compelled his flight from that country, and in 984 he went to Greenland, which had been discovered by Gunnbjörn 100 years before, but not settled. He gave the strange land its incongruous name to attract settlers, and became the leading man in the colony, calling the chief town Gardar. The settlements flourished for about four centuries, when they suddenly disappeared from history, and were remembered only as "the lost colonies of Greenland." It is supposed that the entire people were carried off by the plague known as the "black death," in the latter part of the 14th century. Eric is erroneously set down in some books as the discoverer of the American continent. It was his son Leif Ericsson who first landed on the continent somewhere in New England in the year 1000, and he had been preceded by Bjarne Hierulfson, who sailed along Labrador and Newfoundland in the year 986, but did not land.

ERICÆE, or **ERICA'CEÆ**, a natural order of exogenous plants, consisting chiefly of small shrubs, but containing also some trees. The leaves are opposite or in whorls, entire, destitute of stipules, often small, generally evergreen and rigid. The flowers are sometimes solitary in the axils of the leaves, sometimes grouped in different modes of inflorescence, and are often of great beauty, in which respect no order of plants excels this; the beauty of the smallest species, and of those which have very small flowers, rivaling that of others which are trees profusely covered with magnificent clusters. About 900 species of this order are known, of which the greater number are natives of South Africa, which particularly abounds in the genus *erica*, and its allies—the true heaths (q.v.)—although some of them are also found to the utmost limits of northern vegetation. They are rare within the tropics, and only occur at considerable

elevations. Few species are found in Australia. Many of the E. are *social* plants, and a single species sometimes covers great tracts, constituting their principal vegetation. This is most strikingly exemplified in the heaths of Europe and the north of Asia. Medicinal properties exist in some of the E., as the BEARBERRY (see ARBUTUS). The GROUND LAUREL of North America (*epigæa repens*), also called TRAILING ARBUTUS and MAY-FLOWER, is a general favorite (see FLOWERS, NATIONAL). Narcotic and poisonous qualities are of not unfrequent occurrence. See ANDROMEDA, AZALEA, KALMIA, LEDUM, RHODODENDRON. The berries of some species are edible (see ARBUTUS and GAULTHERIA), although none are much esteemed.—The RHODODENDREÆ have sometimes been regarded as a distinct order, but are generally considered a suborder of E., containing the genera *rhododendron*, *azalea*, *kalmia*, *ledum*, etc. The larger leaves and flowers, and generally also the larger plants of the order, belong to this suborder; which, however, contains also many small shrubs of subarctic and elevated mountainous regions.

ERICHSEN, JOHN ERIC, b. London, 1818; received his medical education at University coll., London, and became prof. of surgery in that institution, 1850. He was pres. of the royal coll. of surgeons of England, surgeon extraordinary to the queen, and had other distinctions. He was the author of several surgical books and pamphlets, especially *The Science and Art of Surgery*, a standard work in England and America, which has been translated into several languages. He d. in 1896.

ERICHT, or **ERROCHT**, LOCH, lies in the n.w. of Perthshire and s. of Inverness-shire, in an uninhabited district, the wildest and most inaccessible in Scotland, amid the Grampian mountains. Its banks rise steeply from the water's edge. It is 14 m. long and nearly 1 m. broad, and it extends in a s.w. direction from near Dalwhinnie on the Dunkeld and Inverness road. By one outlet it joins Loch Rannoch, and by another it runs into Loch Lydoch, its waters ultimately reaching the Tay. Its surface is about 1500 ft. above the sea, and it never freezes. In a cave at the s. end of the loch, prince Charles lay hid in 1746.

ERICSSON, JOHN, a distinguished engineer, was b. in Sweden in 1803. After serving for some time as an officer of engineers in the Swedish army, he removed in 1826 to England, and continued to occupy himself with improvements chiefly on steam machinery. He came to New York in 1839, and two years afterwards was employed on the war-steamer *Princeton* (the first war-steamer having its propelling machinery below the water-line), his own invention of the screw-propeller being used. E. soon became known for the great number and novelty of his inventions, some of which were a steam-boiler with artificial draught, which did away with smoke-stacks and effected an important saving in fuel (this invention was at once applied to railway locomotives); a steam fire-engine; the caloric engine; the screw propeller for steam navigation; a sliding telescopic chimney; machinery to check the recoil of heavy guns; an instrument for measuring distances at sea; the hydrostatic gauge for measuring the volume of fluids under pressure; a meter to measure the amount of water passing through pipes; an alarm barometer; a pyrometer to measure temperature from the freezing of water to the melting of iron; a lead to take soundings without rounding the vessel to the wind; and various modifications of his caloric engine. In the war of the secession he was engaged in building "monitors" (so called from the name of the first one), iron ships with revolving iron turrets for the guns. The first one was built in a little more than three months, and, Mar. 9, 1862, defeated and disabled the confederate iron-clad *Merrimac*. In his later years he attempted to perfect the solar engine, for which heat is obtained from the rays of the sun collected by a huge funnel lined with a reflecting surface. D. 1889. In 1890 the body of Ericsson was removed to Sweden, being conveyed by the United States cruiser *Baltimore*, and in 1893 the state of New York erected a monument to him on the Battery, New York City. See Church, *Life of Ericsson* (1890).

ERIDANUS. See Po.

ERIE, one of the five great lakes which empty themselves by the St. Lawrence, separates Upper Canada on its left from Michigan, Ohio, Pennsylvania, and New York on its right. It is the most southern of the five, receiving at its south-western extremity the waters of lakes Superior, Michigan, and Huron by the river Detroit, and discharging them at its n.e. by the Niagara into lake Ontario. With a length of 240 m., E. has a breadth varying from 30 to nearly 60 m., with an area of 9,600 sq. miles. It is 16 ft. below the Huron, and 333 and 573 respectively above the Ontario and the Atlantic. At its south-western extremity are several wooded and partly cultivated islands, the largest of which is about 14 m. in circumference. It is by far the shallowest of the five great lakes. Its mean depth is stated at 120 ft.; and from this comparative shallowness and the consequent liability to a heavy ground-swell, as well as on account of the small number of good harbors, the navigation is peculiarly difficult and dangerous. The chief harbors on the s., or United States shore, besides the natural harbor of E. itself or Presque Isle, are those of Cleveland, Sandusky City, and Toledo; and on the n. or Canadian shore, ports Dover, Burwell, and Stanley. Lake E. receives no rivers of any consequence. Its commercial importance, however, has been largely increased by art. It is connected by one canal with the Hudson, and by more than one with the Ohio; while, on the British side, it communicates with the Ontario by means of a still more available work, the ship-channel of the Welland. Its navigation generally closes in the beginning of Dec., and the lake remains more or less frozen till Mar. or April. The commercial

importance of this lake has been greatly enhanced the last few years by the establishment of numerous lines of railway connecting its ports with the interior. The amount of traffic on the lake and on these railways is enormous. Lake E. was the scene of a naval engagement between the British and Americans, Sept. 10, 1813.

ERIE, a co. in w. New York, on Lake Erie and Niagara River; 996 sq.m.; pop. '90, 322,981. Co. seat, Buffalo.

ERIE, a co. in n. Ohio, on Lake Erie, drained by Vermilion and Huron Rivers. 260 sq.m.; pop. '90, 35,462. Co. seat, Sandusky.

ERIE, a co. in n.w. Pennsylvania, on Lake Erie between New York and Ohio; 770 sq.m.; pop. '90, 86,074. Co. seat, Erie.

ERIE, city, port of entry, and co. seat of Erie co. Penn., on Lake Erie, 85 miles s.w. of Buffalo and 100 miles n.e. of Cleveland. It occupies the site of a French fort built in 1749, and was laid out in 1795; was incorporated as a borough in 1805, and chartered as a city in 1851. It was the headquarters of Commodore Perry in the war of 1812, and the fleet with which he defeated the British in the naval battle of Put-in-Bay was built and equipped here. The city lies on an elevated bluff, overlooking the lake; the streets are broad, intersecting at right angles. The Union railroad depot is a fine building, 480 feet in length and 88 in width. The handsome Government Building contains the Custom-house, Post-office, and other departments. There are a city hall and an opera house, numerous churches, five national banks, daily and weekly periodicals, a public park containing a soldiers' monument and two fountains, the State Soldiers' and Sailors' Home on Garrison Hill; the Hamot hospital, St. Vincent hospital, Protestant Home for the Friendless, U. S. Marine hospital, and public library. The public schools are well organized, and the Central School occupies a large and attractive building. Near the city is a memorial in the form of a block-house, erected by the State in honor of Anthony Wayne. Natural gas was discovered here in 1889; electric lights and electric street railroads have been introduced, and the water system is excellent. Erie is the only lake port in Pennsylvania, and has the largest land-locked harbor on Lake Erie. It is enclosed by Presque Island, and a breakwater, is nearly five miles long and a mile wide, has a depth of nine to twenty-five feet, and has three lighthouses. The docks are provided with every facility for the transfer of merchandise to and from the railroads. Erie receives a large part of the shipping of the Great Lakes; and the extensive coastwise trade is carried on by steamers and sailing vessels. The principal articles of shipment are lumber, coal, iron ore, and petroleum. Erie is also an important railroad centre, being on the New York, Chicago, and St. Louis, the Pennsylvania, the Lake Shore and Michigan Southern, the Pittsburgh, Shenango and Lake Erie, and the Philadelphia and Erie railroads. The chief industries are the manufacture of boilers and steam-engines, pianos, organs, hollow-ware, stoves, machinery, car-wheels, bricks, leather, pumps, furniture, etc. Pop. '90, 40,634.

ERIE, BATTLE OF LAKE, a naval engagement in the war of 1812 between Great Britain and the United States, fought in Put-in bay, near the western end of lake Erie, Sept. 10, 1813. The American fleet, which had been built at Erie, ran the British blockade on the 12th of August, and sailed west. It consisted of 9 vessels, with 54 guns and 490 officers and men. The British had 6 vessels, mounting in all 63 guns, with 502 officers and men. Only 2 vessels of the American squadron were in the proper sense vessels of war, the others having been built for trade. The American guns, though of heavier caliber, were of shorter range than those of the British; but the American fleet had an advantage in the better quality of its seamen. The American commandant was Lieut. Oliver Hazard Perry. At the opening of the battle Perry's flag-ship *Lawrence* was disabled, but he left her in command of Lieut. Yarnall and shifted his flag to the *Niagara* under a heavy fire. The remainder of the fleet now joined in the attack upon the enemy, compelling the almost immediate surrender of the British flag-ship *Detroit* and three other vessels. The remaining two attempted to escape, but were overtaken and captured. Perry at once sent a dispatch to Gen. Harrison, saying, "We have met the enemy, and they are ours—two ships, two brigs, one schooner, and one sloop." The battle lasted 3 hours, and about 13 men were killed and wounded on each side. The American supremacy on the lakes being established, Detroit was evacuated by the British, and peace established in Michigan. Gold medals were conferred by congress upon Perry and Elliott, the leaders in the battle, and minor rewards upon the other officers and men. In 1858, the remains of the officers killed were buried on Put-in-Bay Island.

ERIE CANAL, connecting the Hudson river at Albany and Troy with lake Erie at Buffalo, is 363 m. in length. It was begun in 1817, and completed in 1825, at a cost of \$7,602,000. Its construction is due chiefly to the foresight and energy of De Witt Clinton, and while it was in progress it was often ridiculed by self-complacent skeptics as "Clinton's big ditch." The enterprise was undertaken and carried through by the state of New York, Clinton being governor during nearly all the period of its progress. As its route lay chiefly through an uninhabited wilderness, it opened for settlement an immense territory. It was subsequently enlarged, and is now 70 ft. broad at the surface, and 56 ft. at the bottom, with a depth of 7 feet. The locks, 72 in number, 57 of

which are double, and 15 single, are 110 ft. long and 18 ft. wide. It is carried by great stone aqueducts across several large streams, and in some places it is cut through solid rock. It is supplied with water from lake Erie, 142 m. from Buffalo to Seneca river. Most of the flow of water is from the w. towards the e., the only exception being between Lodi and the Seneca river, where there is a fall westward through 5 locks. At Rome, a little w. of Utica, a supply of water is received from the Black river canal. Between Rome and Syracuse water is drawn from Cazenovia lake and other reservoirs, while at Syracuse it supplies water to the Oswego canal. Buffalo is 568 ft. above the level of the Hudson at Albany, the difference being overcome by locks at various points. The canal has been immensely successful, contributing largely to the growth of New York, Buffalo, and intermediate places. In 1896 it was estimated that the cost of construction and improvements had aggregated \$52,540,800, and the expenditure of \$9,000,000 more for enlargement was authorized by popular vote in that year.

ERIES, an Indian tribe of the same family as the Hurons and the Iroquois, or Six Nations, once dwelling in the neighborhood of Niagara falls, but forced inland by hostile tribes. About 1653, they were attacked by the Iroquois, and in 1656, nearly exterminated. Those who remained of the tribe became incorporated with the Senecas.

ERIE SHALE, a name given to the extension w. of the Upper Portage and Chemung rocks of New York. It overlies the Huron shale, the latter being the storehouse of petroleum.

ERIGENA, JOANNES SCOTUS, a famous philosopher of the middle ages, was b. probably in Ireland, and flourished during the 9th century. Very little is known regarding his history. He appears to have resided principally in France, at the court of Charles the bald. In the controversies of his time, regarding predestination and transubstantiation, he took part. His philosophic opinions were those of a Neo-Platonist rather than of a scholastic. His love for the mystic doctrines of the old Alexandrian philosophers was shown by his translation of the writings ascribed to Dionysius the Areopagite, which proved to be a wellspring of mysticism during the middle ages. E. held that God is the essential ground of all things, from whom all things emanate, and into whom they return again. Pantheism, therefore, lurks in his system. His principal work is *De Divisione Naturæ* (published by Gale, Oxford, 1681). One of its leading thoughts is the identity of philosophy and religion, when both are properly apprehended. E. uttered his opinions with great boldness, and he exhibited no less subtlety and strength of intellect in their defense. He expressed his contempt for theological dogmatism, and vindicated the authority of reason over all other authority. His words are: "Authority is derived from reason, and not reason from authority; and when the former is not confirmed by the latter, it possesses no value." Consult Hjort's *Joh. E.* (Copenh. 1823); Staudenmayer, *Joh. E.* (Frankfort, 1834); and Taillandier, *Scot. E. et la Philosophie Scholastique* (Strasb. 1843); Möller, *Scotus E.* (1844); Christlieb, *Leben und Lehre des Scotus E.* (1861); and Buchwald, *Leben* (1884).

ERIGENIA (Gr. *erigenes*, born in the spring), a genus of plants belonging to the natural order *umbellifera*; described as follows: calyx-teeth obsolete, petals obovate or spatulate, flat, entire. Fruit twin; the carpels incurved at top and bottom, nearly kidney-form with five very slender ribs, and several oil-tubes in the interstices, the inner face of the reed hollowed into a broad deep cavity. A small and smooth vernal plant with tuberous root, producing one or two divided leaves and a leafy-bracted umbel, from three to nine inches high, of a few white flowers. *E. bulbosa*, popularly called **HARBINGER OF SPRING**, occurs in alluvial soil from western New York and Pennsylvania to Wisconsin, Kentucky and southward.

ERIGERON, a genus of plants of the natural order *compositæ*, sub-order *corymbifera*, having heads (flowers) of many florets, the florets of the ray numerous, in several rows, of a different color from those of the disk. Two or three species are natives of Britain, the most common of which, *E. acris*, has a stem 16 to 18 in. high, narrow entire leaves, flower-stalks forming a kind of corymb, flowers with yellow disk and pale-blue ray. It has a powerful odor, which is said to keep away fleas, and the name **FLEA-BANE** is sometimes given to the plant. Its ashes contain about 5 per cent of potash, for the sake of which it is sometimes collected and burned. *E. Philadelphicum*, a native of North America, with pale-purple ray, and a fetid smell, is valued in the United States as a diuretic.

ERIN, a Celtic name for Ireland (q.v.)

ERINACEUS and **ERINACEADÆ**. See **HEDGEHOG**.

ERINNA, a Greek poetess, concerning the date of whose birth the most different statements are advanced. According to some, she was the intimate friend of Sappho (hence she is likewise called the Lesbian singer), and was born at Rhodes, or on the little island of Telos, situated w. of Rhodes; while others maintain that she lived in the age of Demosthenes; and others again, perplexed by such a wide difference in point of time, have recourse to the hypothesis of two poetesses of this name. E. acquired such celebrity by her epic, epigrammatic, and lyric poems, that her verses were compared with those of Homer, although she died at the early age of 19. The genuineness of the fragments that still exist under her name, has been disputed on good grounds. These

have been collected by Schneidewin in the *Delectus Poesis Graeca Elegiacæ* (Göttingen, 1838). Compare Malzow, *De Erinnae Lesbii vita et Reliquiis* (Petersburg, 1836).

ERIN'YES. See EUMENIDES.

ERIOBO'TRYA. See LOQUAT.

ERIOCAULA CÆÆ, a natural order of endogenous plants, nearly allied to *restiaceæ*, and containing about 200 known species, many of which are aquatic or marsh plants. The E. are chiefly natives of the tropical parts of America and Australia. One species, *ericaulon septangulare*, JOINTED PIPEWORT, is found in the w. of Ireland, and in some of the Hebrides; a little grass-like plant, growing in lakes which have a muddy bottom, and exhibiting small globular heads of flowers. From its botanical affinities, and with reference to geographical distribution, no British plant is more interesting. The E. form a remarkable feature of the vegetation of some parts of South America; but many of the species bear little resemblance to their humble northern congener, being almost shrubby, 4 to 6 ft. high, with leafy, much-branched stems, "each branchlet terminated by a large white ball, composed of a vast number of smaller heads, placed on peduncles of unequal length." Many of them also grow on arid mountainous regions, others in flat sandy grounds, which are flooded in the wet season.—Gardner's *Travels in Brazil*.

ERIODEN'DRON, a genus of trees of the natural order *sterculiaceæ*, natives of tropical countries, the thick woody capsules of which contain a kind of wool surrounding the seeds. These trees are therefore sometimes called WOOL-TREES. The wool of *E. samanna* is used in Brazil for stuffing pillows. *E. anfractuosum*, of which one variety, found in the East Indies, is sometimes called *E. Indicum*, and another, found in Africa, *E. guineense*, is a tree of great height, 150 ft. or more. The African variety or species is called RIMI and BENTANG. Park mentions it by the latter name. Barth says it is generally to be seen growing near the principal gate of large towns in Hansa. Its wood is soft and spongy, chiefly used for making canoes. The seeds of *E. Indicum* are eaten in Celebes. They are roundish, and of the size of peas. The trees of this genus have palmate leaves. The flowers are large and beautiful.

ERIS, in Greek mythology, sister of Mars, daughter of Nyx (night), and sister of Nemesis. Eris, or "strife," is represented at first as insignificant, but growing until her head touches the heavens. It was Eris who at the marriage festival of Peleus and Thetis flung on the table the golden apple inscribed to the fairest of the fair, for which Juno, Venus, and Minerva contended. Virgil gives Eris the name of Discordia.

ERITREA, an Italian colony on the Red Sea, extending from Cape Kasar to the sultanate of Raheita, and having a coast-line of about 670 miles, an area of 88,500 sq. m., and population estimated at 450,000. A treaty with Egypt in 1891 determined its boundary on the Egyptian side and a treaty with Abyssinia, in 1889, fixed the boundaries between it and the latter country. In 1895 the Italians occupied Kassala, and, after a war with Abyssinia, annexed the province of Tigré, but they were unable to retain the Abyssinian territory. King Menelek having won the decisive victory of Adowa in 1896, regained all the country to the south of the Mareb, Belesa, and Muna rivers, and secured the recognition of the absolute independence of the country. Throughout the colony agriculture is in a backward condition, the summer droughts necessitating extensive irrigation for the raising of crops. There is abundant pasturage, and the population is mainly engaged in the raising of herds, but it is to a great extent nomadic. Massowah, with a population of 7775 in 1893, is the capital of the colony. A railway, seventeen miles in length, connects it with Saate.

ERIVAN', or IRWAN, a government of Russia on the borders of Persia, Georgia, and Armenia; 10,670 sq. m.; pop. '92, 703,511. The largest river is the Aras, or Araxes, and Ararat is the principal mountain. There are valuable mines of gold and other minerals, and salt is produced in large quantities. Chief town, Erivan.

ERIWAN' (Persian *Rewdn*), the fortified capital of Russian Armenia, situated to the north of Ararat, in the elevated plain of Aras or Araxes, lat. 40° 10' n., long. 44° 32' e., 3,312 ft. above the level of the sea. It consists of the town properly so called, and the fortress, which is surrounded on three sides by high walls, and provided with aqueducts, a stone bridge over the Zenga, which here falls into the Araxes. E. was formerly the capital of the Persian province of Aran, celebrated for its silk. During the war between Russia and Persia, E. was stormed by the Russian gen., Paskewitsch, who received the surname of Eriwanski; and by the treaty of peace concluded at Turkmanjai, 22d Feb., 1828, it was given up by Persia to Russia, along with the province of the same name. It is now an important Russian post, as in former times it formed the bulwark of Persia against the Turks, and afterwards against Russia. Pop. '90, 12,449.

ER'LANGEN, a t. of Bavaria, is situated in the midst of a well cultivated district, on the right bank of the Regnitz, 10 m. n. of Nürnberg. It is a handsome town, and is surrounded by walls pierced by seven gates. It is divided into the old and new towns, the latter founded in 1686 by Christian, markgraf of Bayreuth. E. is the seat of a university, of a gymnasium, of agricultural and industrial schools, and other institutions. The university, however, is the chief building. It was founded in 1742, and is celebrated as a school of Protestant theology, has a library, zoological and mineralogical collections, etc. E. owes its prosperity to the migration thither of a number of refugees from

France, who were compelled to flee on the revocation of the edict of Nantes, and who introduced many new branches of manufacture at Erlangen. It has various manufactories and is specially known for its breweries. E. became a Bavarian possession by the treaty of 1809. Pop. '90, 17,559.

ERLAU (Hung. *Eger*), an episcopal city of Hungary, in the co. of Heves, of which it is capital, is situated on both banks of the river Erlau, in a delightful valley skirted with vine-clad hills. It is surrounded by old walls. The principal buildings are the lyceum, with a valuable library, and an observatory 172 ft. high; the cathedral, the episcopal palace, the Franciscan and the Minorite monasteries, a richly embellished Greek church, a county hall, and the new barracks. E. has also a gymnasium, an episcopal seminary, a normal and drawing school, a hospital founded in 1730, and other important institutions. The cultivation of the vine is the principal occupation of the inhabitants. The famous E. wine is produced in considerable quantities. Pop. '90, 22,427, most of whom are Roman Catholic in religion, and Magyar in race. E. owes its importance to the very old bishopric founded here by St. Stephen in the beginning of the 11th c., and which, in 1804, was raised to an archbishopric.

ERLKÖNIG, in German, is the name applied to a poetical, personified, natural power which, according to German poetical authorities, prepares mischief and ruin for men, and especially for children, through delusive seductions. The name, not connected with the root *erle*, is synonymous with *Elfen König*. The E. was introduced into German poetry from the Sagas of the north, through Herder's translation of the *Erlekönig's Daughter* from the Danish, and has become universally known through Goethe's ballad of the *Erlekönig*, set to music with remarkable power by Schubert.

ERMAN, ADOLPH, Egyptologist, the son of Georg Adolph Erman; born in Berlin in 1854; educated at Leipsic and became extraordinary professor, 1883, and ordinary professor, 1892, in the Leipsic University. In 1885 he was appointed director of the Egyptian division of the Royal Museum. Among his writings are *Die Pluralbildung des Ägyptischen* (1878); *Neu-ägyptische Grammatik* (1880); *Deutsche Medaillene des 16. und 17. Jahrhunderts* (1884); *Ägypten und Ägyptisches Leben in Altertum* (1885-7); *Die Sprache des Papyrus Westcar* (1889); *Die Märchen des Papyrus Westcar* (1890); *Ägyptische Grammatik* (1894). In 1889 he became associated with Brugsch in the publication of the *Zeitschrift für Ägyptische Sprache*, etc.

ERMAN, GEORG ADOLPH, son of Paul; b. Germany, 1806. In 1828-30, he traveled around the world chiefly to make observations in magnetism, and published an account of his journey, from which the portion describing Siberia was translated into English. Erman published other works on plants and animals, and after 1841 was the principal editor of a scientific publication chiefly concerning Russia. He was also for a number of years professor of physical science in the university of Berlin. He d. 1877.

ERMAN, PAUL, 1764-1851; b. Berlin. At first intending to study for ordination in the church, he turned to pursue physical sciences and became a teacher in the French gymnasium in Berlin, and later in the military academy. When the university of Berlin was founded he was chosen professor of physics, and held the office until his death. He made important discoveries in electricity, magnetism, optics, and physiology, and wrote valuable works on these subjects.

ERMELAND, an old division of Poland, now a district in East Prussia, extending about 50 miles from northwest to southeast. *It is a Roman Catholic diocese.

ERMONVILLE, a village in the s.e. of the department of Oise, in France, in the possession of the Girardin family. It is celebrated for its beautiful and extensive parks, and as being the resting-place of Rousseau, for which reason it is much visited in summer by strangers from Paris. It was also the residence of Gabrielle d'Estrées, the mistress of Henry IV., who inhabited a hunting-tower, part of which is still standing, and bears her name. It became still more celebrated after the death of Rousseau in 1778. During the revolution, his ashes were removed to the Pantheon, but conveyed back to E. after the restoration. It had nearly been purchased by the *Bande Noire*, but a larger sum was offered by Stanislaus de Girardin, the well-known liberal deputy, and E. was preserved for the lovers of art, of nature, and of historical monuments.

ERMINE, white fur, with black spots; the reverse of which, or a black fur with white spots, also used in heraldry, is called *contre ermine*. E. is commonly used to difference the arms of any member of a family who is connected with the law. A cross composed of four E. spots is said to be a cross ermine. See MINIVER.

ERMINE, or STOAT, *Mustela erminea*, a species of weasel (q.v.), considerably larger than the common weasel, but much resembling it in general form and other characters, as well as in habits. The E. is almost 10 in. in length, exclusive of the tail, which is fully 4½ in. long. It is of a pale reddish-brown color in summer, the under parts yellowish-white, the tip of the tail black; in winter—in cold countries or severe seasons—the upper parts change to a yellowish-white or almost pure white, the tip of the tail, however, *always* remaining black. This change takes place more frequently in the northern than in the southern parts of Britain, but sometimes even in the s. of England; and when it is only partially accomplished, the animal presents a piebald appearance, and very often remains so during the milder winters of Britain. It is in its winter dress that it is called E., and yields a highly valued fur; more valuable, however, when obtained from the coldest northern regions than from more southern and temperate

countries. In its summer dress it is called stoat. It displays indomitable perseverance in the pursuit of its prey, which consists very much of rats, watervoles, and other such small quadrupeds; with young hares and rabbits, grouse, partridges, etc. The eggs of birds are as welcome to it as the birds themselves. The E. is a native of all the northern parts of the world. Its range extends even to the s. of Europe. It delights in moorish districts, and is tolerably abundant in the n. of Scotland. It is from Norway, Lapland, Siberia, and the Hudson's bay territories that the E. skins of commerce are obtained, which are used not only for ladies' winter garments, but for the robes of kings and nobles, and for their crowns and coronets. E. has thus obtained a distinct recognition in heraldry. In making up E. fur, the tails are inserted in a regular manner, so that their rich black shall contrast with the pure white of the rest of the fur.

ERNE, a river and lake in the s.w. of Ulster province, Ireland. The river rises in the s. of Cavan co., in the small but beautiful lough Cowna. It runs n. and n.w., merging in lough Oughter, in Cavan co., and in lough Erne in Fermanagh co., and passes Enniskillen and Ballyshannon. It then flows through the s. corner of Donegal co. into Donegal bay. It has a total course of 60 miles. On the river, at Ballyshannon is a salmon-leap fall, over a rocky ledge 20 ft. high and 150 yards broad, and the river leaps over another rocky ledge near Belleek, $2\frac{1}{2}$ m. below the lower end of the loch. Lough Erne, one of the finest lochs in the kingdom, is the most attractive feature of Fermanagh co., which it bisects lengthways, and almost entirely drains. It extends 40 m. from s.e. to n.w., and consists of two lakes, the upper and lower, joined by a narrower part 10 m. long, and assuming in parts the character of a river, with Enniskillen midway between the two lakes. The upper lough is 12 by 4 m. in extent, 10 to 75 ft. deep, 151 ft. above the sea, and has 90 green hilly islets. The lower lough is 20 by $7\frac{1}{2}$ m. in extent, 100 to 266 ft. deep, 148 ft. above the sea, and has 109 similar islets. On one of the islets is a round tower. They contain salmon, trout, pike, bream, and eels. The scenery around is singularly varied and beautiful.

ERNE, *Haliaeetus*, a genus of birds of the family *falconidae*, and of the eagle group; differing from the true eagles in the greater length of the bill, in the toes and lower part of the tarsi being destitute of feathers, and generally, also, in frequenting the sea-coast and the banks of lakes and rivers to feed on fish, in feeding like vultures on carrion almost as readily as on newly killed prey, and in inferior courage. The only British species is the **COMMON E.** (*H. albicilla*), also known as the sea eagle or white-tailed sea eagle. It is much more common in Britain than the golden eagle, is sometimes seen even in the s. of England and in inland districts, occasionally visiting deer-parks to prey on very young fawns or to devour dead deer; but is of more frequent occurrence in the n. of Scotland, doing considerable injury to flocks in Sutherlandshire, particularly during the season of young lambs. Its favorite haunts, where it roosts and makes its nest, are the shelves and ledges of stupendous precipices on the coast, where its scream often mingles with the noise of the perpetual surge. It sometimes also breeds on crags beside inland lakes, as at the lakes of Killarney, and more rarely even on trees. Fishes are certainly its favorite food, although its mode of procuring them is not well known; but water-fowl are also its very frequent prey. It is found in most parts of Europe, and even in the islands of the Mediterranean, but is more abundant in the n. of Europe and in Siberia. It is not known as a native of America. In size, the E. is inferior to the golden eagle, being seldom more than 33 in. in its whole length. The general color of the plumage is brown, the head having a paler yellowish tinge, the tail in the adult bird is pure white. The young, sometimes called the cinereous eagle, has a grayer plumage and mottled tail.—Another notable species of this genus is the **WHITE-HEADED E.** (*H. leucocephalus*) of America, also called the white-headed eagle, bald eagle, and sea eagle, the chosen symbol of the United States. It is a bird of about the same size with the common E., with dark-brown plumage, and—in an adult state—the head, neck, tail, and belly white. It is found in almost all parts of North America, visiting the arctic regions in summer, but abounding chiefly in the southern states between the Atlantic and the Mississippi. It frequents both the sea-coast and the lakes and rivers, and may be often seen sailing through the column of spray at the falls of Niagara. It is very fond of fish, which it procures by wading in shallow streams, and also by compelling the osprey to relinquish prey just taken. The soaring and evolutions of the birds in the air on such occasions are described as sublime. The white-headed E. feeds also on lambs, fawns, poultry, &c.; kills swans, geese, and other water-fowl; and does not disdain to compel vultures to disgorge for its use the carrion which they have swallowed. On account of its habits and dispositions, Franklin expressed his regret that it had been chosen as the symbol of his country.—More nearly resembling the common E. is another North American species, the **BIRD OF WASHINGTON** (*H. Washingtonii*).—Australia produces a beautiful species (*H. leucogaster*), and numerous species are found in other parts of the world, amongst which are some of comparatively small size, as the **PONDICHERY KITE** or **BRAHMAN KITE** (*H. ponticerianus*) of India, which is constantly to be seen fishing like a gull in the rivers of that country, and is by the Hindus considered sacred to Vishnu.

ERNEST AUGUSTUS, 1771–1851; fifth son of George III. of England. As duke of Cumberland he was for a long time a member of the house of lords, where he was an

extreme tory. When his brother William IV. died, 1837, he became king of Hanover, where he became notorious for tyranny and licentiousness. His blind son George was his successor, reigning until Hanover was annexed to Prussia.

ERNESTI, JON. AUG., the founder of a new school of theology and philosophy, was b. at Tennstädt, in Thuringia, 4th Aug., 1707. He studied at Pforta, Wittenberg, and Leipsic; but after having been appointed rector of the Thomas school in Liepsic, in 1734, turned his attention chiefly to the old classical literature, and the studies connected with it. In 1742, he became professor extraordinary of ancient literature in the university of Leipsic; in 1756, professor of rhetoric; in 1759, professor of theology; and died 11th Sept., 1781. E. paved the way to theological eminence by a thorough study of philology, and was thus led to a more correct exegesis of the Biblical authors, and to more liberal views of theology in general. In fact, it is mainly to him that we owe the proper method of theological exposition, in so far as it rests upon correct grammatical elucidation. He showed his ability as an accurate critic and grammarian, in his editions of Xenophon's *Memorabilia of Socrates*; the *Clouds* of Aristophanes, *Homer*, *Callimachus*, *Polybius*, *Suetonius*, and *Tacitus*; but above all, by his admirable edition of Cicero (5 vols., Leip., 1737-39), to which he added a *Clavis Ciceroniana*, by way of supplement. He was also the first reviver of true and manly eloquence in Germany. His theological writings are numerous. The most remarkable are the *Initia Doctrinæ Solidioris*; the *Institutio Interpretis Novi Testamenti* (translated into English); the *Anti-Muratorius* (1755); and the *Opuscula Theologica* (1792). Compare Bauer, *Formule ac disciplinæ Ernestianæ indoles* (1782); Stallbaum, *Die Thomas-schule zu Leipzig* (1839).

ERNST, elector of Saxony, the founder of the Ernestinian line, or the elder branch of the princely house of Saxony, b. 1441, eldest son of the elector Friedrich the Mild, and of Margaret, archduchess of Austria. When only 14 years of age, he was seized and carried off from the castle of Altenburg, along with his brother Albrecht, but was speedily recaptured. This incident, known in German history as the stealing of the princes (*Prinzenraub*), has been described with extraordinary vividness by Carlyle in the *Westminster Review*, Jan., 1855. He succeeded to the electoral dignity on the death of his father in 1464, but governed in common with his brother for 21 years. In 1485, however, E. and Albrecht divided the paternal possessions, when the former obtained as his share Thuringia, the half of the district then called Osterland, with Voigtland, the Franconian estates of the house, the electoral dignity, and the dukedom of Saxony. E. was a man who took a great interest in the welfare of his people. Against injustice, tyranny, and lawlessness, he was implacable. He died at Kolditz in 1486. It is next to impossible to trace the course of the Ernestinian line through the labyrinthine mazes of the endless German genealogies; it is sufficient to say that after 1638, the Ernestinian line was represented by the dukes of Weimar, who gradually obtained the whole possessions of the house. Johann, duke of Weimar, who died in 1605, left several sons, the eldest of whom, Wilhelm, became the founder of four different branches, all of which, however, were reunited under Ernst August, duke of Weimar, who died in 1748. After 1815, the duchy of Weimar became the grand-duchy of Saxe-Weimar-Eisenach, and its present ruler is of course the direct representative of the Ernestinian line. The other three families by which it is now also represented are those of Meiningen, Saxe-Coburg-Gotha, and Altenburg.

ERNST I., surnamed the Pious, duke of Saxe-Gotha and Altenburg, founder of the house of Gotha, was b. at the castle of Altenburg, 24th Dec., 1601. He was the son of that Johann, duke of Weimar, mentioned in the previous article, who died in 1605, and was thus connected with the main Ernestinian line. E. was the ninth of ten brothers, the youngest of whom was the famous Bernhard (q.v.) von Weimar. He received an excellent education from his mother, Dorothea Maria von Anhalt. After the arrival of Gustavus Adolphus in Germany, E. entered the Swedish service, and in various engagements exhibited great courage and skill, completing the victory of the Protestants at Lützen, after the fall of Gustavus. After the battle of Nördlingen, 26th Aug., 1634, E. withdrew from the theater of strife, and for the rest of his life devoted himself to restoring the prosperity of his territories, which had been frightfully devastated during the thirty years' war. He died in 1675. Of his seven sons, the eldest, Friedrich, continued the line of Gotha, while the third became the founder of the house of Meiningen, and the seventh, the founder of the house of Saalfeld. E. is a fine type of the old German Protestant prince. Zealously attached to the doctrines and government of the Lutheran church, he exercised a constant watch over its religious and educational interests. With the formalism, however, that often characterizes "strictly religious" people, he compelled his children to learn the whole Bible by heart. He was much interested in the cause of Christianity abroad, and invited to his court the abbot Gregorius from Abyssinia, besides sending thither on a religious embassy Joh. Mich. Wansleb of Erfurt. He also carried on a correspondence with the king of Ethiopia and the patriarch of Alexandria. His line became extinct by the death of Friedrich IV. in 1825.

ERNST II. (AUGUST KARL JOHANNES LEOPOLD ALEXANDER EDUARD), duke of Saxe-Coburg-Gotha, elder brother of the late prince Albert (q.v.), b. at Coburg 21st June, 1818. Both brothers received an admirable literary and scientific education. The family to which he belongs is a branch of the Ernestinian line, having been founded in

1680 by Albrecht, second son of Ernst the pious (q.v.). When E. had completed a university curriculum at Bonn, he entered the military service of the king of Saxony, but left it on the occasion of his marriage with the daughter of the grand-duke of Baden. In 1844, E. succeeded his father as duke of Saxe-Coburg-Gotha. In his opinions and aspirations, imbued with the spirit of his age, he has introduced into his little dominions many beneficial reforms, and allayed not a few long-standing jealousies. Yet one regrets to say, that his enlightened views of his duty as a ruler have not been generally appreciated by his subjects. During the stormy period of 1848-49, by spontaneous concessions on the one hand, and on the other by an energetic repression of the political anarchists, he contrived to save his territories from the perils of revolution. In the Slesvig-Holstein war, E. took a prominent part, and on the 5th April, 1849, won the battle of Eckenförde. E. was a great advocate for the unity of the German nation, and took a prominent part in most of the efforts made in that direction. His leisure hours were devoted to music and the fine arts. His operas, *Casilda*, *Santa Chiara*, and *Diana von Solanges*, are well known in Germany. In 1861 he published a pamphlet vindicating his government, and in 1864 an account of a tour in Egypt. He died in 1893.

ERNST, HEINRICH WILHELM, an eminent violinist, b. at Brünn, in Moravia, in 1814. He early became a pupil of the Vienna conservatorium, studying under Seyfried and Mayseder. At the age of 16, his talents excited much interest on his appearance in public at Munich, Stuttgart, and Frankfurt; and he soon afterwards performed in Paris. His first visit to London was in 1843; and he returned in subsequent years, spending the intervals in Paris and in different parts of Germany. His playing was characterized by immense brilliancy, combined with passion and sentiment. He suffered much from acute neuralgia, which latterly interfered with the exercise of his art; and the last seven years of his life were spent at Nice, where he died Oct. 8, 1865. E.'s compositions have generally a bravura character, and include works for the violin and orchestra, quartettes, etc.

EROS. See CUPID.

EROSION, the influence of a stream or river in hollowing out its channel. Even the smallest streams, when running over soft strata, as clay or sand, cut out channels, and remove the eroded materials. Hollows thus produced have been observed among the stratified rocks. One that occurs in the coalfield of the forest of Dean has been carefully described. The trough was found to branch, when traced in the progress of mining, over a considerable area, and to assume all the appearances of a little stream, with small tributaries falling into it. When the hollows thus abraded are of considerable extent, "*valleys of erosion*" are produced. Many of the earlier geologists held that rivers had hollowed out their own valleys. The immense amount of materials brought down by rivers, and deposited at their mouths as deltas, shows without doubt that they have contributed materially to produce inequalities on the earth's surface; but the examination of the geological structure of valleys, plainly testifies that almost every great hydrographical basin has derived its form originally from some other agency, although its outline may have been subsequently altered by the continued action of currents within it.

EROSTRATUS. See HEROSTRATUS.

EROTIC (from the Greek *eros*, love), signifying in general whatever is marked by love or passion; but the term is chiefly applied to poetical pieces of which love is the predominating subject.

EROTOMANIA, a species of mental alienation caused by love. See MANIA.

ERPENIUS (Latinized from Thomas van Erpen), one of the earliest and most eminent of European orientalists, was b. at Gorkum, in Holland, 7th Sept., 1584. At an early age, he was sent to Leyden, where he directed his attention first to theology, but afterwards more particularly to the study of oriental languages. Having completed his educational course, he traveled through England, France, Italy, and Germany; and in 1613, became professor of oriental languages at Leyden. Here he erected an Arabic press in his own house, caused new types to be cut, and not only wrote but printed a great number of important works bearing on his favorite studies. The professorship of Hebrew not being vacant at the time of E.'s translation to the university of Leyden, a second Hebrew chair was founded expressly for him in 1619. Soon after this he was appointed oriental interpreter to the government, in which capacity he read and wrote replies to all official documents coming from the east. Such was the elegance and purity of his Arabic, as written at this time, that it is said to have excited the admiration of the emperor of Morocco. Towards the close of his life, tempting offers of honors and distinction came pouring in upon him from all parts of Europe; but he was never prevailed upon to leave his native country, where, in the midst of an eminent career, he died 13th Nov., 1624. Although the present standard of oriental knowledge in Europe is much in advance of that of E.'s day, there is no doubt that it was through him principally that eastern, especially Arabic studies have become what they are. With hardly any better material than a few awkwardly printed Arabic alphabets, he contrived to write his famous grammar (*Grammatica Arabica, quinque libris methodice explicata*, Leyden, 1613; recent edition by Michaelis, Gött. 1771), which for 200 years,

till the time of Silvestre de Sacy, enjoyed an undisputed supremacy; and there are many who think his *Rudimenta* unsurpassed, even at the present day, as a work for beginners. Among his other important works the best known is his *Proverbiorum Arabicorum Centuriæ Duæ* (Leyden, 1614).

ERRATA, the list of errors with their corrections placed at the end of a book. From greater carefulness in correcting the sheets of a work in passing through the press, errors in sense or typography are now much more rare than formerly; in many instances, indeed, books are now produced without a single error which needs to be pointed out and corrected. As an example of one, for "errors" read "errors" on first line of this article. On this subject interesting particulars are given in Disraeli's *Curiosities of Literature*, of which the following is a specimen: "Besides the ordinary *errata* which happen in printing a work, others have been purposely committed, that the *errata* may contain what is not permitted to appear in the body of the work. Wherever the inquisition had any power, particularly at Rome, it was not allowed to employ the word *fatum*, or *fata*, in any book. An author, desirous of using the latter word, adroitly invented this scheme: he had printed in his book *facta*, and in the *errata* he put, 'for *facta*, read *fata*.'"

ERRATICS, the name given to the water-worn blocks of stone that have been washed out of the boulder clay, or are still inclosed in it, because they have generally been derived from rocks at a distance. See **BOULDERS** and **BOULDER-CLAY**.

ERRHINES (Gr. *en*, in, and *rhin*, the nose), medicines administered locally to produce sneezing and discharge from the nostrils, in catarrh, and in various disorders of the head and eyes. Common snuff, and other vegetable irritants are so used.

ERROR, PROCEEDINGS IN. In the language of the law, the word error denotes not merely a mistake in the ordinary meaning of the word, but such a misapprehension of the law by the court, or such a deviation from established principles, as to constitute an injury to one party so serious in its nature as to entitle him to carry his case to a court of review. It has been defined as a mistake in a judicial determination of a court to the prejudice of the legal rights of one party; and this mistake may be either in a wrong decision on the merits or in ruling wrongly upon an incidental point involved. The method of obtaining a reversal of the wrong ruling or judgment may be either by appeal or through a *writ of error*. Often the word error is used by abbreviation in place of the expression writ of error, as in saying that a certain judgment may be "reversed on error." A court of review to which application may be made for the righting of the injury caused by the error is often called a court of error. Thus the titles of the highest court of appeals in Connecticut is the Supreme Court of Errors; in New Jersey and Delaware the courts of the same standing are called the Supreme Courts of Errors and Appeals. The writ of error is the precept or process issuing from the court of review to the lower court, pointing out that error has been committed, and requiring the record of the case to be sent up to the higher court for examination. The method of review by writ of error originated in the common-law practice, and corresponded to the appeal in equity practice. Under the common law the error might be either of fact or of law; in the former case the court of original jurisdiction might correct the error, in the latter the matter was taken up by writ to a superior court. In the English courts this method of reviewing the errors of inferior courts is abolished (as is also the bill of exceptions) by the Judicature Acts of 1875; the present method is simply by a motion for a rehearing.

In the United States in some states the original common-law practice has been retained, though usually with modifications, but in many, in civil actions, a direct appeal has been substituted. Under proceedings in error the party who sues out the writ in the appellate court is called the plaintiff in error, the opposing party the defendant in error. The proceeding by a writ of error differs from a motion for a new trial and from a motion in arrest of judgment in that it does not lie until final judgment has been rendered. It may not be obtained for minor or technical defects in the preliminary pleadings, but only for such errors as would be of serious importance on a demurrer or a motion in arrest of judgment; in such cases the writ of error is a matter of right. Formerly a writ of error was not allowed in criminal cases, but under the modern practice it is accepted as a method of reviewing proceedings in such cases after a conviction by a jury. Under the practice of the English courts, and in almost all of the states in this country, an appeal on the merits of the case, such as may be taken in a civil case, does not lie in a criminal action, and instead a writ of error may be resorted to to obtain a reviewing of the proceedings in the court in which the conviction has taken place. Such proceedings in error will lie only for a defect in substance, one which is a part of the record, not for formal defects in the indictment.

ERRORS. In all observations, *E.* must be made. The best instruments have imperfections; and no man, however equable his temperament, can always rely on his making a proper use of his senses. As in astronomy numerical correctness in the results of instrumental measurements is of the first consequence, it is the constant care of the observer to detect and make allowance for errors. The three principal sources from which they may arise are—1st, External or incidental causes, such as fluctuations of weather, which disturb the amount of refraction; changes of temperature, affecting the form and position of instruments, etc.; 2d, *E. of observation*, being such as arise from

inexpertness, defective vision, slowness in seizing the exact instant of an occurrence, atmospheric indistinctness, etc.; and such E. as arise from slips in clamping and momentary derangements of the instrument; 3d, Instrumental defects, owing to E. in workmanship, and such as arise from the instrument not being properly placed—called E. of adjustment. The first two classes of E., so far as they cannot be reduced to known laws, vitiate the results of observations to their full extent; but being accidental, they necessarily sometimes diminish and sometimes increase them. Hence, by taking numerous observations under various circumstances, and by taking the *mean* or *average* of the results obtained, these E. may be made to destroy one another to a great extent, and so far may be subdued. With regard to the third class, it is the peculiarity of astronomical observations to be the ultimate means of detection of all defects of workmanship and adjustment in instruments, which by their minuteness elude every other mode of detection. See sir John Herschel's *Outlines of Astronomy*, s. 138 *et seq.* It may be mentioned, however, that the method of subduing E. of the first two classes by the law of average is not applicable in all cases. In certain cases, recourse must be had to what is known as the method of least squares. See SQUARES, METHOD OF LEAST; see also PROBABILITY.

ERSCH, JOHANN SAMUEL, the founder of German bibliography, was b. at Grossglogau, in Lower Silesia, 23d June, 1766; and exhibited from an early period a decided bias towards that branch of literature in which he afterwards obtained so high a reputation. At Halle, where he was sent to study theology in 1785, he devoted himself to historical investigations. After several vicissitudes, he obtained, in 1800, the office of librarian to the university of Jena. Three years later, he was called to Halle as professor of geography and statistics; and in 1808, was appointed, in addition, principal librarian. He died at Halle, 16th Jan., 1828. E. was long engaged in miscellaneous bibliographical work for other scholars; but in 1818, along with Gruber, commenced the publication at Leipsic of the *Allgemeine Encyclopädie der Wissenschaften und Künste* (Universal Encyclopædia of the Sciences and Arts), a work of immense value. By his *Handbuch der Deutschen Literatur seit der Mitte des 18 Jahrh. bis auf die Neueste Zeit* (Handbook of German Literature from the Middle of the 18th Century to the most recent Time, 4 vols., 1812–14), he first established modern German bibliography in the technical sense of the word; and by its completeness, accuracy, and mode of arrangement, it is undoubtedly fitted to serve as a model for the imitation of other nations.

ERSE (a corruption of *Irish*), the name given by the lowland people of Scotland to the language spoken by the inhabitants of the western highlands, as being of Irish origin. See BRETT'S AND SCOTS. The proper name is Gaelic (q.v.).

ERSEK-UJVAR'. See NEUHAUSEL.

ERSKINE, Rev. EBENEZER, the founder of the secession church in Scotland, was the son of the Rev. Henry Erskine, minister of Chirnside, in Berwickshire, a descendant of the noble family of Mar, and was b. June 22, 1680. He studied at Edinburgh, and after acting for some time as tutor and chaplain in the family of the earl of Rothes, he was licensed to preach the gospel by the presbytery of Kirkcaldy in 1702. His abilities and excellent character soon brought him into notice, and in the following year he was appointed minister of Portmoak in the shire of Kinross. Here he applied himself indefatigably to the study of the Scriptures, and became so deeply convinced that to preach "Christ crucified" was his grand and constant duty as a minister, that after some time the earnestness, unction, and piety which now marked his discourses, became exceedingly attractive to the people accustomed to the chilling "legalism" which then predominated in the Scottish pulpit. E.'s popularity was not confined to the parish of Portmoak; serious Christians from all parts of the country were eager to enjoy occasionally the benefits of his ministry, and on sacramental occasions, he had frequently attendants from the distance of 60 or 70 miles. In 1731, he was translated to Stirling, after having discharged the pastoral office in Portmoak for 28 years. Previous to this event, however, the religious peculiarities of E. had brought him into unpleasant relations with some of his brethren, by the interest which he exhibited in a book called the *Marrow of Modern Divinity*, marked by its strong evangelicalism of doctrine and sentiment. After his transference to Stirling, E. distinguished himself by his advocacy of popular rights in the settlement of ministers; and ultimately involved himself in such antagonism to the church of Scotland, or at least to the ruling party in it of the time, that, along with other three clergymen, he was deposed in 1733. (For an account of the circumstances which led to these depositions, see UNITED PRESBYTERIAN CHURCH). He was shortly after joined by his brother Ralph and several other ministers. They now virtually formed a distinct sect, but they still continued to occupy their parish churches. An effort was made in 1734 to restore them to their legal connection with the church; it was unsuccessful. In 1736, E. and his friends formally seceded, but still it was not till 1740 that they were ejected from their churches. Shortly after this, a furious, and, as it seems to people now-a-days, a contemptible squabble broke out among the seceders in regard to the propriety of taking the burgess-oath. The result was a division of the sect into two bodies, the Burghers and Antiburghers. See

UNITED PRESBYTERIAN CHURCH. E. was the leader of the Burghers. He died June 2, 1754.

ERSKINE, HENRY, 1746-1817; a Scotch lawyer, brother of Thomas, lord Erskine. He was lord advocate of Scotland in 1782 and 1806. In politics he was a whig; but his fame rests chiefly on his wit and tact as an advocate.

ERSKINE, JOHN, of Carnock, and afterwards of Cardross, an eminent Scottish jurist, and professor of Scots law in the university of Edinburgh, was the son of the Hon. John Erskine of Carnock, third son of lord Cardross, whose descendants have now succeeded to the earldom of Buchan. John Erskine, the father, was a man of importance in his day, not only on account of the family to which he belonged, which even then had been prolific in historical characters, but in consequence of his personal qualities and the positions which he held. Having been forced to quit Scotland from his attachment to the Presbyterian religion, he retired to Holland, and became an officer in the service of the prince of Orange. At the revolution, he accompanied William to England, and as a reward for his services, was appointed lieutenant-governor of Stirling castle and lieut.col. of a regiment of foot. John E., the younger, born 1695, became a member of the faculty of advocates in 1719, but did not succeed as a practitioner of the law. On the death of Alexander Bain in 1737, Mr. E. was nominated to succeed him in the chair of Scots law, an office the duties of which he performed with great reputation for 28 years. For many years Mr. E. made use of sir George Mackenzie's (q.v.) *Institutions of the Law of Scotland* as his text-book; but in 1754 he published his well-known *Principles of the Law of Scotland*, which were thenceforth used for that purpose by himself and by his various successors down to the present time. On his retirement from the professorship in 1765, Mr. E. occupied himself in preparing his more important work, *The Institutes of the Laws of Scotland*, but it was not published till 1773, five years after his death. Mr. E. was twice married—first to Miss Melville, of the noble family of Leven and Melville, by whom he left the afterwards celebrated clergyman, John Erskine; and, second, to Ann, second daughter of Stirling of Keir, by whom he had four sons and two daughters. As a legal writer, Mr. E. is inferior to none of the Scottish jurists, with the single exception of lord Stair, who had the benefit of the more learned and wider judicial training of earlier lawyers, who were educated in a continental school. In consequence of the extent to which lands changed hands in Scotland subsequent to the rebellions, feudal conveyancing became the most prominent subject of study amongst the lawyers of Mr. E.'s day, and the principles of commercial law, of which Stair laid the foundation, and which have become so important in our own time, were somewhat thrown into the shade. The labors of Mr. Bell in these departments have again brought the law of Scotland into connection with the general current of European law and mercantile practice throughout the world. But of all those departments which constitute the law of Scotland, as developed by the usages and forms of society in the country itself, there is at the present day no clearer, sounder, or more trustworthy expositor than Mr. Erskine.

ERSKINE, Rev. Dr. JOHN, son of John Erskine, of Carnock, the author of the *Institutes of the Law of Scotland*, was b. June 2, 1721, studied at the university of Edinburgh, and in 1743 was licensed to preach by the presbytery of Dunblane. In the following year, he was ordained minister of Kirkintilloch, where he remained until 1753, when he was presented to the parish of Culross, in the presbytery of Dunfermline. In 1758, he was translated to New Greyfriars church, Edinburgh; in 1766, the university of Edinburgh conferred on him the honorary degree of doctor of divinity; and in 1767, he was promoted to the collegiate charge of Old Greyfriars, where he had for his colleague Dr. Robertson. In the general assembly of the church of Scotland, he was for many years the leader of the popular or evangelical party; and there the openness and integrity of his character secured him the confidence and affection of his friends, and the esteem and respect of his opponents. Between him and Principal Robertson, the leader of the moderate party, there was a courteous and honorable friendship; and the funeral sermon which he preached on the death of his colleague, did equal honor to E.'s head and heart. He died Jan. 19, 1803. E.'s writings are exceedingly numerous. They consist of essays, letters, sermons, dissertations, and pamphlets, etc., mainly of a religious character, and exhibit a superior degree of ability. Sir Walter Scott, in his *Guy Mannering*, gives a graphic and accurate description of his powers as a preacher.

ERSKINE, Rev. RALPH, brother of Ebenezer, was b. at Monilaws, in Northumberland, Mar. 18, 1685, and after completing the usual course of study incumbent on a minister, was ordained to the parish church of Dunfermline in 1711. Sympathizing with the sentiments of his brother Ebenezer, he withdrew from the judicatures of the established church in 1737. In the controversy concerning the Burgess-oath, he also took part with his brother. E. died Nov. 6, 1752. His fame rests chiefly on his *Gospel Sonnets* and other religious works, which were once highly popular.

ERSKINE, THOMAS, Lord ERSKINE, was the youngest son of Henry David, tenth earl of Buchan; and was b. in Edinburgh, 10th Jan., 1750. Although his father, at the period of his birth, was reduced to an income of £200 a year, he transmitted to him the blood of a race which had been prolific in men of great ability, and had been ennobled

before the era of genuine history. The countess, who was the daughter of sir James Stewart, of Goodtrees, in the co. of Midlothian, was not only a godly Presbyterian and a skillful housewife, but a gifted and accomplished woman. After E. had attended for some time the high school of Edinburgh, the family removed to St. Andrews, at the grammar school of which place, and subsequently at the university, though never it would seem as a matriculated student, Thomas E. received the rest of such education as fell to his share. His desire was to study for a profession; but his parents, who had sent his eldest brother, lord Cardross, to Leyden, and were educating his second brother, Henry, afterwards the well-known Harry E., for the Scottish bar, could not afford the expense of a third learned education, and sent him to sea as a midshipman. In this capacity he served for four years, until the death of his father, when he purchased a commission in the first royals, and was for some time stationed at Minorca, where he employed his leisure time in the study of English literature. On his return to London, his birth, his acquirements, the elegance of his manners, and volubility of his conversation, led to his being warmly received in the best circles. It was then that he had the controversy with Dr. Johnson on the respective merits of Fielding and Richardson which Boswell has recorded; and that he published a pamphlet on the prevailing abuses in the army, which, though anonymous, was well known to be his, and obtained a great circulation. E. now grew tired of the army as a profession, in which he saw little chance of promotion; and while in this humor, an accidental interview which he had with lord Mansfield at an assize court, determined him to prosecute the study of law. E. was admitted a student of Lincoln's Inn, 26th April, 1775, and on the 13th Jan., 1776, he entered his name on the books of Trinity college, Cambridge, as a gentleman commoner. Many anecdotes are told of the privations which E. underwent when studying for the bar—how he lived on “cow-heel and tripe,” dressed so shabbily as to be quite remarkable, and boasted that *out of his own family* he did not know a lord. Such stories, though probably exaggerated, proved that he endured considerable privations—considering his rank—in fitting himself for the legal profession. Lord Campbell says, that “during Easter and Trinity terms he excited a great sensation in the dining-hall by appearing with a student's black gown over the scarlet regimentals of the royals; *probably not having a decent suit of plain clothes to put on.*” Though E. was aided by his aristocratic connection, his rise was still very wonderful. Without the advantage of a business training, or what, probably even in those days, was far more important, a business connection, he rose into practice with almost unprecedented rapidity. After his first speech, the attorneys actually flocked round him with their retainers, and in telling the story, he used sometimes to bring the number which he received before quitting Westminster hall up to sixty-five! His two first clients were officers in the navy—capt. Baillie, who held an office in Greenwich hospital, against whom a rule had been obtained calling upon him to show cause why a criminal information for a libel reflecting on lord Sandwich's conduct as governor of the charity, should not be filed upon him; and admiral Keppel, who was tried by a court-martial at Portsmouth for incapacity and misconduct in an encounter with the French fleet off Ushant; and in both cases E. derived benefit from his own early connection with the service and the special information which he thus possessed. Admiral Keppel sent him two £500 notes as a fee. From this time forth, E.'s good fortune as an advocate was uninterrupted. In 1783, he was returned to parliament for Portsmouth. Four years and a half after he was called to the bar, he had cleared £8,000 to £9,000, besides paying his debts, he had got a silk gown, business of at least £3,000 a year, and a seat in parliament, and had made his brother lord advocate. In parliament, on the other hand, he failed so egregiously in his first speech as to leave scarcely any hope in the bosoms of his admirers, and what is very singular, his failure and lord Eldon's took place the same night. To some extent the phenomenon was accounted for by Sheridan's remark when he said to him: “Erskine, you are afraid of Pitt, and that is the flabby part of your character.” But notwithstanding his political mortifications, his professional career went on with increasing brilliancy. In 1786, he was made attorney-general to the prince of Wales, by whom he was warmly patronized, but towards him and every one else he exhibited that manly independence which was the best part of his character. The fact of his appearing as counsel for Thomas Paine is more to his credit, than even the brave and honest speech which he made in his defense; whilst his removal in consequence from his office is, as lord Campbell has said, a lasting disgrace to those from whom the measure proceeded. Throughout the political trials which occurred in this country at that troubled period, he enacted the same manly part. When E. was proposed for the woolsack, an office far beyond his legal attainments, the king, George III., in consenting, exclaimed: “What! what! well! well!—but remember he is your chancellor, not mine.” Yet his decisions as lord-chancellor, according to lord Campbell, are not so much *bad* as *superficial*, though by some equity practitioners they are spoken of as the *apocrypha*. E. was engaged in the defense of queen Caroline. He died 17th Nov., 1823.

ERSKINE, THOMAS, of Linlathen, 1788–1870; a Scotch writer on theology and religion. He was a descendant of the earl of Mar, regent of Scotland under James VI. He studied law at Edinburgh university, and, 1810, became a member of the faculty of

advocates. He retired from the bar in 1816, on succeeding to the family estate after the death of his brother. Erskine's principal works are: *Remarks on the Internal Evidence of the Truth of Revealed Religion*; *Essay on Faith*; *Unconditional Freeness of the Gospel*; *The Brazen Serpent*; *Doctrine of Election*; and other papers.

ERUPTIVE ROCKS. See IGNEOUS ROCKS.

ERYNGO, *Eryngium*, a genus of plants of the natural order *umbelliferae*, having simple umbels, which resemble the heads of composite flowers, a leafy involucre and leafy calyx, and obovate, scaly fruit destitute both of ridges and vittæ. The species are numerous, mostly natives of the warmer temperate parts of the world, with alternate, simple, or divided leaves, which have marginal spines. One species only is common in Britain, the SEA ERYNGO, or SEA HOLLY (*E. maritimum*), which is frequent on sandy sea-shores; a very stiff, rigid, and glaucous plant. *E. campestre* has also been found in England and Ireland, but is very rare. Its root was formerly much employed in some parts of Europe as a tonic. That of *E. maritimum* is used in the same way, and possesses the same properties, being sweet and aromatic. It is sold in a candied state, and was formerly reputed stimulant, restorative, and aphrodisiac. Shakespeare makes Falstaff allude to the snowy color and supposed properties of this now almost disused sweetmeat, for the preparation of which Colchester has long been famous above all other places. E. root has also been used as an aperient and diuretic. Linnæus recommends the blanched shoots of *E. maritimum* as a substitute for asparagus. *E. fetidum*, a native of the warm parts of America, is called fit-weed in the West Indies, a decoction of it being much used as a remedy in hysterical cases. *E. aquaticum*, a native of low wet places in North and South America, is called rattlesnake weed and button snakeroot. The root is diaphoretic and expectorant, and has a spurious reputation as a cure for the bite of a rattlesnake.

ERYSIMUM, a genus of plants of the natural order *cruciferae*, tribe *sisymbriæ*. The pod is four-sided. *E. cheiranthoides*, a branching annual, about 18 in. high, with lanceolate scarcely toothed leaves and small yellow flowers, is found in many parts of Europe, and also in North America. It is not uncommon in waste places and cultivated grounds in Britain, but may perhaps have been originally introduced for its medicinal use. Its seeds were formerly much employed as an anthelmintic, from which it has the name of WORM-SEED. It is also called TREACLE MUSTARD, because it was employed as an ingredient in the famous *Venice treacle*. *E. perfoliatum* is cultivated in Japan for the fixed oil of its seeds. Some of the plants formerly referred to E. are now included in other genera, as *sisymbrium* and *alliaria* (q.v.).

ERYSIPELAS (Gr. derivation uncertain), an inflammatory and febrile disease of the skin, attended by diffused redness and swelling of the part affected, and in the end either by desquamation or by vesication of the cuticle, or scarf-skin, in the milder forms, and by suppuration of the deeper parts in the severer varieties of the disease (phlegmonous erysipelas). E. affects, in a large proportion of instances, the face and head; it is apt to be attended with severe and typhoid fever (see FEVER), and often with great disorder of the nervous system, arising in some instances from inflammation of the membranes of the brain. In other parts of the body, severe or phlegmonous E. is apt to be succeeded by protracted and exhausting suppurations, and sometimes by diseases of the bones, or inflammations of the internal organs. E. is frequently an epidemic (q.v.) disease; it is also very apt to recur in a person who has been attacked once or oftener; and this is especially true of the form which affects the face. It is seldom that depletion is allowable in E., but the bowels should be well cleared out in most cases, and a diuretic (q.v.) given, after which the treatment consists for the most part in watching narrowly the progress of the case, keeping up the strength as well as possible, and obviating special dangers as they occur. In some cases, iron is used as a specific remedy.

ERYTHEMA (Gr. *eruthainō*, I redden), a minor form of erysipelas (q.v.), presenting the same tendency to diffusion and redness, but not so much swelling, and little disposition towards suppuration, or even vesication. E. is chiefly dangerous when it presents itself in a wandering shape, attended with slow consuming fever. The muriated tincture of iron, in doses of twenty drops in water every hour or two, has been regarded as a specific in this disease, as well as in erysipelas. Some forms of E. are distinctly connected with constitutional diseases, as gout, rheumatism, syphilis, etc., and depend for their cure on the removal of the cause.

ERYTHRÆA. See CENTAURY.

ERYTHRÆAN SEA, in ancient geography, a name applied to an indefinite expanse of the Indian ocean, but including the Persian and Arabian gulfs. Later geographers restricted the name Erythræan to the Arabian gulf.

ERYTHRINA. See CORAL FLOWER.

ERYTHRONIUM, a genus of bulbous-rooted plants of the natural order *liliaceæ*, with drooping flowers and the segments of the perianth reflexed. *E. dens canis*, the DOG-TOOTH VIOLET, so called because of the resemblance of its little white bulbs to dogs' teeth, is a well-known ornament of our flower-borders in spring. It is a native of the

central parts of Europe and s. of Siberia. Anthelmintic properties are ascribed to the bulbs. Those of *E. Americanum* are emetic.

ERYTHROPHLÆUM, a genus of trees of the natural order *leguminosæ*, sub-order *mimosæ*. *E. Guineense*, a native of Guinea, is a very large tree, 100 ft. high, remarkable for the great quantity of red juice which every part of it contains, and interesting on account of the employment of this juice by the natives for an ordeal to test the innocence or guilt of a person accused of crime. The juice is swallowed in large draughts, and those who remain uninjured by it are supposed to be innocent.

ERYTHROXYLA'CEÆ, a natural order of exogenous plants, allied to the *malpighiaceæ*. They are trees or shrubs, with alternate simple leaves, stipules, flowers growing from amidst scale-like bracts, calyx of five sepals, corolla of five petals, each petal having a curious appendage—a plaited scale—at the base, 10 stamens united at the base, a three-celled ovary with two cells empty, and the third containing a single ovule, three styles, and the fruit a drupe. Nearly 100 species are known, natives of warm countries, and chiefly of tropical America. To this order belongs the coca (q.v.). The wood of some of the species is bright red; that of *erythroxylon* (Gr. red wood) *suberosum* is used in Brazil for dyeing, and a permanent red is obtained from it. That of *E. hypericifolium* is the *bois d'huile* (oil-wood) of Mauritius.

ERYTREA. See ERITREA.

ERYX, an ancient city and mountain in the w. part of Sicily near the sea-shore. There was once a temple to Venus on the mountain. Eryx was taken and retaken in the Carthaginian wars, and was partially destroyed by Hamilcar. The site of the old city is now occupied by a convent, and the mountain by a Moorish castle, used as a prison, around which is the modern town of San Giuliano.

ERZBERG. See EISENERZ.

ERZERUM' or **ERZROUM**, a province embracing a large portion of Turkish Armenia, bordering on Russia and Persia, between 39° and 41° n. and 39° and 44° e.; pop. 1885, 645,702. It is mainly a high table-land, and is traversed by several mountain ranges, between which are fertile valleys. The chief rivers are the Aras, or Araxes, the Euphrates, and the Kur. Chief town, Erzerum.

ERZERUM', or **ERZROUM'**, properly *Erserum*, a strongly fortified t. in Turkish Armenia, in lat. 39° 55' n., and long. 41° 20' e., not far from the northern source of the Euphrates. It is situated in a high, but tolerably well cultivated plain; its site being 6,200 ft. above the level of the sea. The climate is cold in winter; and dry in summer. E. is the residence of an English, a Russian, and a French consul; and its pop. is estimated at 60,000, of whom the majority are Mohammedans, but there are many Christians, for the most part Armenians, who carry on a brisk trade, and have thus attained to a degree of prosperity unusual in the east. The copper and iron wares of E. have acquired a wide celebrity. Situated at the junction of the important highways leading from Trebizond, Transcaucasia, Persia, Kurdistan, Mesopotamia, and Anatolia, E. forms an entrepôt of commerce between Europe on the one hand, and the interior of Asia, and particularly Persia, on the other. The streets, the houses of which are built chiefly of volcanic stone cemented with mud, are narrow, crooked, and filthy; and ruins of fortifications and of buildings formerly magnificent, everywhere meet the eye. The town consists of the fortress, strictly so called, and four suburbs. The fortress, which is inclosed by a high wall, has, on the w., a citadel called Ijkaleh, with many curious monuments, and a mosque of Christian origin. The fortress also contains the residence of the chief magistrate, some caravanseries, and a few elegant houses belonging to the higher order of officials and Mohammedan merchants. The suburbs boast numerous mosques, several Armenian churches, and a number of large bazars and caravanseries. E. imports shawls, silk goods, cotton, tobacco, rice, indigo, etc.; and exports corn, sheep, and cattle, horses, mules, and gall-nuts. The principal trades carried on are tanning, dyeing morocco, and blacksmiths' and coppersmiths' work. It is the seat of an Armenian bishop, and of Protestant and catholic missions. E. is a very ancient town. Its Armenian name was *Garin Khalakh*. Near it stood the old Syro-Armenian town of Arsen. When the Seljuks captured this place the inhabitants fled to a fortress at E., which the Seljuks accordingly called *Arsen-er-Rum*, i.e., Arsen of the Romans (or Byzantines), whence the modern Erzerum. In 1201, it fell into the hands of the Seljuks; of the Mongols in 1242; and finally, in 1517, into those of the Turks. It still, however, continued to be the most important city in the country, and at the commencement of the 19th c. had a pop. of 100,000 inhabitants. In the war of 1829, between the Turks and Russians, the taking of E. by the latter decided the campaign in Asia. E. was an important military center during the war of 1877-78, and much hard fighting was done in its neighborhood. In Dec., 1877, the Russians closed round the city, already hard pressed, and reduced its defenders to the utmost distress: in Feb., 1878, it was surrendered to Russia. The Russians held it till Oct., 1878, when it was given up to the Turks.

ERZGEBIRGE ("Ore Mountains"), the name given to the chain of mountains, rich in metals, stretching in a south-westerly direction, on the confines of Saxony and Bohemia, from the valley of the Elbe to the Fichtelgebirge, in long. 12° 20' e. In the

s., it rises to a height of from 2,000 to 2,500 ft., forming a steep wall of rock; in the west, it forms broad, slaty plateaus, and gradually slopes down towards the Saxon side to the level districts of Altenburg and Leipsic. In consequence of this formation, the streams flowing southward are small, while the n. side of the chain, which is well wooded, presents a series of romantic, and occasionally fertile and thickly peopled valleys, watered by the Mulde, the Pleisse, and their numerous tributaries. The town of Gottesgabe, the site of which is the highest in Germany, is situated towards the s. of the E. range, in long. 12° 54' e., at an elevation or 3,162 feet. The Keilberg, the highest point of the range, is 3,802 ft. above the level of the sea.

ESAIAS. See **ISAIAH**.

ESARHAD DON was the son of Sennacherib, king of Assyria. Nothing is known, positively, concerning him until his accession to the throne after the murder of his father by two other sons. The length of his reign cannot be determined, but the number of his military expeditions and the extent of his architectural works show that it must have continued many years. The order in which its principal events occurred is not known. He reigned personally at Babylon as well as Nineveh, having palaces at both cities and residing alternately in each. This fact explains and justifies the Scripture statement that Manasseh, king of Judah, when taken captive, was brought before the king of Assyria at Babylon. The monuments indicate that E. was one of the mightiest of the Assyrian kings. He conquered all Asia between the Persian gulf, the Armenian mountains, and the Mediterranean sea. On the w., his influence extended over Cilicia and Cyprus; on the e., he made war against tribes which his fathers had not known; and on the s., asserted authority over Egypt and Ethiopia. He built numerous temples that shone with silver and gold, and palaces that surpassed in magnificence those of his predecessors. The s.w. palace at Nimrud, built by him, was of extraordinary size, its great hall being 220 ft. by 100, and its porch 160 ft. by 60. It was adorned with the usual array of winged bulls, colossal sphinxes, and sculptured slabs of alabaster. When first uncovered it was apparently in a good state of preservation, but it was soon evident that fire had raged through it, splitting and calcining the alabaster slabs, which consequently crumbled to dust when exposed to the air. In his unfinished palace at Calah the slabs around the rooms were smoothed in readiness for the inscription, but when they were turned, in order to be carried away, their backs were found to be sculptured, showing that they had been taken from an older building, and that E., having consigned to oblivion the records of a former reign, was preparing to celebrate his own exploits on the reversed sides of the slabs.

E' SAU ("hairy" or "rough"), the eldest son of Isaac, and twin-brother of Jacob. As E. grew up, he became "a man of the field," a cunning hunter, and his father's favorite. He seems to have been a wild, rough, hearty Bedouin, or son of the desert, thinking nothing of to-morrow, but living with joyous carelessness from day to day. This is apparent from the manner in which he allowed Jacob to defraud him of his birthright, although it carried with it, besides many temporal advantages, the *Covenant-blessing* itself. After this transaction, E., when 40 years of age, married two Canaanitish women, "which were a grief of mind unto Isaac and to Rebekah" (Gen. xxvi. 35). Then follows the narrative of Jacob's personation of his brother, and his securing irrevocably the blessing to himself. E. now swore to kill his brother, whereupon Rebekah sent Jacob to his uncle Laban in Padanaram. E. next married his cousin Mahalath, the daughter of Ishmael; and appears to have established himself in his wife's country, to the s. of Palestine, in Mt. Seir. Here he lived probably as a predatory chief. When Jacob was returning from Padanaram, E. encountered him with 400 of his Bedouins. The meeting was a touching one. The wild borderer at least was in earnest. "Esau ran to meet him, and embraced him, and fell on his neck, and kissed him" (Gen. xxxiii. 4). His anger had long died out. E. next appears at the burial of his father Isaac, whom he seems to have loved with the warm and simple affection of a child of nature, and having obtained his share of the property, "went into the country from the face of his brother Jacob" (Gen. xxxvi. 6). From E. the region of Mt. Seir took the name of Edom (q.v.), and his posterity are generally called Edomites.

ESCALADE (Fr. from Lat. *scala*, a ladder), in siege operations, is a mode of gaining admission within the enemy's works. It consists in advancing over the glacis and covert-way; descending, if necessary, into the ditch by means of ladders; and ascending to the parapet of the curtain and bastions by the same ladders differently placed. The ladders are either procured on the spot, or are sent out with the siege-army. A convenient form is in pieces of 12 ft. length, fitting end to end by means of sockets. A firing-party is usually told off, to keep down the fire of the enemy upon the escaladers, especially a flank fire lengthwise of the ditch, which might sweep them off with terrible rapidity. The leaders of an E. constitute a "forlorn hope."

ESCALOP-SHELLS are often used in heraldry to signify that the bearer has made many long voyages by sea. As the Pilgrim's (q.v.) emblem, they were commonly given to those who had been to the crusades; they came to be regarded as indicating either that the bearer or his ancestor had been a crusader. The escalop-shell was the emblem of

St. James the Great, and is generally met with in churches dedicated to him. The more ordinary form of the name is scallop-shell. See PECTEN.

ESCAMBIA, a co. in s. Alabama, on the Florida border, intersected by Escambia and Conecuh rivers, and the Louisville and Nashville railroad; 972 sq. m.; pop. '90, 8666, includ. colored. The soil is level and sandy, and not very productive. Co. seat, Brewton.

ESCAMBIA, a co. in w. Florida, on the Gulf of Mexico, between the Escambia and Perdido rivers, intersected by the Pensacola and Perdido and the Louisville and Nashville railroads; 680 sq. m.; pop. '90, 20,188. It has a level, sandy soil, to a large extent covered with pine forests. Co. seat, Pensacola.

ESCAPEMENT is the term applied to that part of the machinery of a watch or clock by which the onward revolving motion produced by the moving power, whether weights or spring, is brought into contact with the regulating movement of the pendulum or balance-wheel. See HOROLOGY.

ESCAPE WARRANT is a warrant issued in England for the apprehension of persons who have escaped from the queen's bench or fleet prisons. This power is conferred by 1 Anne, s. 2, c. 6, followed by 5 Anne, c. 9. The warrant may be issued by any judge of the court wherein the action was tried, or judgment and execution obtained, upon oath in writing, of the escape of the party, made before himself, or before one of the commissioners to take oaths. The apprehension may be effected on Sunday. The person apprehended is committed to the charge of the sheriff of the county, who is made responsible for his safe keeping.

ESCARP, in fortification, is the side or slope of the ditch next the rampart, and of the parapet itself. When the ditch of a fortress is dry, the E. is usually faced with mason-work, to render it difficult of ascent; and behind this facing (*revêtement*) there are often passages or casemates for defense. In temporary fortifications, the *revêtement* is sometimes of wood; and in field-works, palisades at the foot, or fraises on the *berme* or edge of the ditch, are held sufficient. The E. is always made at as large an angle as the nature of the soil will allow; the design being to offer the greatest possible obstacle to an assailant. See *illus.*, FORTIFICATION, vol. VI.

ESCARS are large heaps of gravel, consisting chiefly of carboniferous limestone, that were accumulated during the pleistocene period. They occur in central Ireland, but are identical with the *ösar* of Sweden; and under the name of *kames*, they are not unknown in Scotland. The gravel is often heaped into narrow ridges 40 to 80 ft. high, and from 1 to 20 m. long.

ESCAUT. See SCHELDT.

ESCHAR (Gr. *eschara*), a slough or portion of dead or disorganized tissue. The name is commonly applied to artificial sloughs produced by the application of caustics (q. v.).

ESCHAROTIC (Gr.), causing an eschar. See CAUSTIC.

ESCHATOL'OGY, the doctrine concerning the last things, in the Christian system, treats of the millennium, the future coming of Christ, the state of man after death, the resurrection, last judgment, and final condition of mankind.

I. *The Millennium and the Future Coming of Christ*.—The xxth chapter of Revelation speaks of a period of a thousand years during which Satan shall be bound in the bottomless pit, and the souls of them who had been beheaded for the witness of Jesus and for the word of God, and who had not worshiped the beast or his image, and had not received his mark upon them, shall live and reign with Christ. This is called the first resurrection. Many persons, uniting this passage with others and professing to interpret them literally, teach that the millennium will be preceded by the second coming of Christ in visible glory, and by the resurrection of the glorified saints to reign with him on earth. Their opinion on this important point naturally colors their interpretation of a large portion of Scripture and of their practical duties as Christians. Many of them are very earnest and confident in the maintenance of their views. In opposition to them the usual faith of Christians has been that the millennium will precede the visible coming of Christ,* and will be accomplished through the divine blessing, given in copious measures, on the diligent use of such means of grace as the church has always employed. They who adopt this view regard the passage in the Revelation concerning the first resurrection as figurative (as the rest of the book manifestly is), and the coming of Christ, promised in the New Testament, as: 1. An exhibition of his providential government over the history of the world and of the church. In this sense the destruction of Jerusalem by the Romans, followed by the dispersion of the Jews, Matt. xxiv. 4-28, and the establishment of the kingdom of Christ, with the gathering of his elect, 29-44, were foretold by him as a coming of the Son of Man. 2. His spiritual presence with his people during their lives and work on the earth, and at the time of their death, Matt. xviii. 20 John xiv. 23, 3. 3. His glorious appearing to judge the world, Matt. xxv. 31; I. Thes. iv. 16.

II. *The State of Man after Death*.—1. Materialists, who assert that the soul is only a function of the body say, consistently enough, that at death both perish together. 2. Pantheists, who maintain that man is a transient form of God's existence, teach that the soul has no consciousness after death. The race is immortal, but the individual

man is not. Flowers bloom from generation to generation, but each flower blooms but once, and after that exists no more. 3. Some, who are neither materialists nor pantheists, suppose that the soul cannot act or manifest itself without a bodily organism, material or other, and that consequently at death it must either cease its activity, or be furnished at once with a new body. The latter part of the alternative many of the class referred to do not hesitate to accept. "Do the dead cease to exist?" they ask, and quickly reply, "No; for there is the spiritual body as well as a natural body; at death the latter is dissolved, but the former is not affected; therefore the life of the soul, still clothed upon, remains unharmed." Those who reject this theory deny that the soul is dependent on matter for the exercise of its faculties, or for its personality, or its susceptibility. Certainly God, who is purely a spirit, is not thus dependent: and as men have a spiritual nature like that of God, the theory cannot be true concerning them. To this it is rejoined that the theory of a "spiritual body" does not require that it be any form of *matter*. 4. Many who reject or disregard the Bible, while they do not deny that the soul continues to exist after death, say they have no proof that it does. Some of this class when dying have declared that they were taking a leap in the dark. 5. The Scriptures teach the continued existence of the soul after death. The Pentateuch teaches it when it calls God the God of Abraham, Isaac, and Jacob after their death, thus implying that they still lived. The Psalms teach it when they speak of the soul as redeemed from the power of the grave, and as being satisfied when it awakes in God's likeness. The prophets teach it when they declare that the dead shall live, that they shall awake and shine as the stars forever and ever. The New Testament teaches it by the promises of Christ, "I give unto them eternal life and they shall never perish;" and by the affirmation of the apostles that Christ hath abolished death and brought life and immortality to light. 6. All who believe in a future resurrection and final judgment necessarily believe in an intermediate state of the soul after death, in some respects different both from its former condition in this life and from its final condition in the life to come. The question is, What is the nature of this intermediate state? (1) Some suppose that between death and the resurrection the soul continues in an unconscious state. Since the Bible speaks of death as a sleep, and since a dead body is as incapable of sleep as a stone, it must be (they think) the soul that sleeps. To this a sufficient answer is that in death the outward appearance of the body is exceedingly like sleep, and that it is for this reason death is compared to it; just as, on the other hand, the actual sleep of a living person has been called the "counterfeit of death." (2) The Roman Catholic church teaches that all who, dying in the peace of the church, are not perfect, pass into purgatory, concerning which they say that it is a state of suffering designed for both expiation and purification; that the duration and severity of the suffering are proportioned to the sinfulness of the sufferers; that the duration may be shortened and the severity alleviated by the prayers of the saints and the sacrifice of the mass; and that it is the prerogative of the church to remit, entirely or in part, the penalty of sins under which the soul suffers. This doctrine was not held, in its completeness, even by Roman Catholics until a comparatively late period. "Purgatory as a burning away of sins," said Dollinger at the Bonn conference of Old Catholics in 1875, "was an idea unknown, in the east as well as the west, until Gregory the Great introduced it. What was thought was that after death those who were not ready for heaven were kept for some time in a state of preparation, and that the prayers of the living were an advantage to them. Gregory the Great added the idea of a tormenting fire. This the schoolmen gradually converted into doctrine which they associated with papal indulgence, till it came to apply to the dead generally, which of course made all seek for indulgence. It went on to have degrees (some could receive indulgence for a few of their sins, others for all), so that eventually the pope, having already the keeping of heaven and the dominion on earth, obtained also sovereignty under the earth." (3) The general faith of Protestants is not uniform on this point; probably the prevalent view is "that the souls of believers are at their death made perfect in holiness, and do immediately pass into glory." According to this view the intermediate state of believers is one of perfect freedom from sin and suffering, and of great exaltation and blessedness. This is not inconsistent with believing that after the second coming of Christ and the resurrection the soul will be still more exalted and blessed. And with it may be mentioned, as not altogether contrary to it, the opinion of many, in both ancient and modern times, that "sheol" and "hades" are general terms for the intermediate dwelling-places of the dead, one division of which is "paradise," the happy abode of the saved; and the other "gehenna," the wretched abode of the lost.

III. *The Resurrection.*—Faith in the resurrection of the body, as additional to the future life of the spirit, rests on revelation. Swedenborgians (and some others in part agree with them) hold that man in this life has two bodies, one external and material, which dies and is buried, never to rise again; the other internal and psychical, which, incapable of death, passes in union with the soul into the invisible world as its spiritual body: the resurrection, therefore, in their view occurs at the moment of death. The Scriptures, in their obvious sense, plainly teach an actual resurrection of the dead. "All that are in the graves shall come forth." "That which is sown a natural body shall be raised a spiritual body." "The corruptible must put on incorruption, and the

mortal immortality." In some true and noble sense, the body raised will be personally representative of that deposited in the grave; for St. Paul, denying the identity of the two—"thou sowest not the body that shall be," and declaring the divine mystery—"God giveth to the seed a body as it hath pleased him," asserts the reciprocal pertinence of the two, each to each—"and to every seed his own body." Zoologists teach that with every living germ there is an immaterial principle by which one species is distinguished from another. In like manner, some suppose that as the soul is created to be incarnate, it is endowed with forces to that end; that, besides its rational, voluntary, and moral faculties, it has what may be called a vital force, which secures the formation of a body suited to its necessities and sphere. Concerning the nature of the spiritual body, nothing can now be known except what Scripture has revealed. From this source we learn that it will be an organism not of flesh and blood, but specially suited to the new state of being in which man is to live and act. Yet it is probable that it will be the glorified likeness of the human form as it existed in this life—the ideal human organism actualized.

IV. *The Final Judgment.*—The consciences of men affirm that God as the judge of all the earth must do right, and also that his moral government, as administered in this present world, does not fully render unto all according to their character and desert: "There are just men unto whom it happeneth according to the work of the wicked; and there are wicked men unto whom it happeneth according to the work of the righteous." Consequently, reason, even among the heathen, calls for a settlement of the destinies of men, so that the justice of God may be vindicated. The Scriptures declare that a final settlement will be made: "God shall bring every work into judgment, with every secret thing, whether it be good or whether it be evil." This judgment is represented as a definite future event, in which the destiny of men and of angels will be determined and manifested: "God hath appointed a day in which he will judge the world in righteousness." The word "day," while not to be taken literally, implies, it is claimed, a definite and limited period. Christ, as God manifest in human personality, and as having made atonement for the sins of mankind, will be the judge: "The Father hath given him authority to execute judgment also because he is the Son of Man." The ground of judgment will be the deeds done in the body; and the character and life of each man will be judged according to the light that he had, and (if he knew the gospel) according to the relation (determined by his own choice) which he sustains to Christ: "He that heareth my word and believeth on him that sent me hath everlasting life, and shall not come into condemnation; but is passed from death unto life."

V. *The End of the World.*—The Scriptures teach that the existing heaven and earth are to be replaced by a new creation: "They shall wax old as a garment, and be changed." "The heavens shall pass away with a great noise, and the elements shall melt with fervent heat; the earth also and the works that are therein shall be burned up. Nevertheless, we, according to his promise, look for a new heavens and a new earth wherein dwelleth righteousness." "I saw a new heaven and a new earth; for the first heaven and the first earth were passed away, and there was no more sea." 2. In the Scriptures, the abode of the saved is sometimes called the better country, even the heavenly; sometimes "the city which hath the foundations;" and sometimes a "house not made with hands," as when the Savior said, "In my Father's house are many mansions, I go to prepare a place for you." 3. The blessedness of the heavenly state may be conceived of as arising, in part, from the vision of God in his glory as seen in the Lord Jesus, from the experience of his love, from the enlargement and glorification of the mental faculties, from the absence of sin and sorrow, from intercourse and fellowship with the holy and happy society of heaven, and from the possession of all good. 4. The wretchedness of the lost—of which, as to its nature or modes, little appears in the Bible, while its certainty and reality are abundantly declared—is conceived of as consisting, partly, in eternal separation from the society and influence of the good, and from fellowship with God's glory, blessedness, and love; in the presence and influence of ungodly and wicked beings; in remorse of conscience and in the power of sin in the soul. Some claim scriptural authority for conceiving of it as consisting in the ultimate and utter extinction of the personal being, sinking under sin. 5. The blessedness of the saved and the wretchedness of the lost appear in the Scriptures as without end. After much debate as to exegesis of the texts involved, the drift of the most recent critical scholarship may be said to be unmistakably towards this decision—that while the Greek language did not possess, as the Greek thought did not require, terms which necessarily carried the meaning of absolute eternity, as we now employ that word (e.g., in reference to the being of God), Christ and his apostles used, in reference to future reward and retribution, such words expressive of unlimited duration as were furnished by the language of their time; and that the whole manner and bearing of their speech on this point seems to intend an avoidance of any suggestion of an end. Especially in regard to retribution, the fact is recognized that the most decisive utterances concerning it are not from the apostles, but from Christ himself, who as the "light of the world," and the professed Savior of men, would have been quick to supply the hope of limited duration, had any such hope been within his thought. There is, however, to be noted a tendency towards statements on this point far less sweeping and dogmatic than were

formerly advanced, and a distinct enlargement of the bounds of admitted variations of belief concerning it among the denominations called evangelical. See IMMORTALITY.

ESCHEAT (Fr. *échoir*, from Lat. *cadere*, to fall out or happen). An incident of feudal tenure of real property, whereby the course of descent from the vassal or tenant as ancestor to an heir became obstructed, and the property fell back or reverted to his immediate lord. In order to complete his title acquired by escheat, it was necessary that the lord should perform some act, such as entering and taking possession of the land or bringing an action at law for its recovery. The principle or theory, upon which he thus recovered the property, was that, since none but those who were of the blood of the person last seized could inherit, and there were no persons of that blood in being and capable of inheriting, the land must result back to the lord of the fee, by or through whom it was given. According to the law of England, escheat was either *propter defectum sanguinis*—i.e., because there were no heirs of the deceased tenant, or *propter delictum tenentis*—i.e., because the blood of the tenant was *attainted* or corrupted, so that those who were related to him as heirs could not inherit. Such corruption of blood occurred when the tenant was convicted of treason or felony. The rule applied to all felonies, and frequently produced much hardship. This form of escheat was peculiar to English law. It is to be carefully distinguished from forfeiture of lands to the crown for treason or felony, which has prevailed in other countries besides England. When this latter penalty was enforced for the crime of treason, the offender forfeited all his lands absolutely to the crown; when it was enforced for any other felony, the forfeiture to the crown was of all the offender's estates for life absolutely, and of all his estates in fee simple for a year and a day, after which they escheated to his immediate lord. (See FORFEITURE.) In English law, escheat as a result of conviction of crime is now abrogated; and all forfeiture for crime, except in cases of outlawry, is abolished. (Statute 33 and 34 Vict. ch. 23.) It is provided, by the Constitution of the United States, that "Congress shall have power to declare the punishment of treason; but no attainder of treason shall work corruption of blood, or forfeiture, except during the life of the person attainted." (Art. 3, § 3.) This indicates the policy which has moulded the laws of the various states, so that escheat as the result of crime is practically unknown in this country.

Since the feudal system has no existence, even in theory, in the United States, escheat, in its technical sense as in force in England, does not and cannot exist here. But by virtue of statutory provisions, generally found in the state constitutions, the title to the property of one who dies without heirs, is transferred to the state in which it is situated; and this transfer is still denominated an escheat. In some states the common law, which precluded aliens from inheriting real property, is still operative. But in many states such disability of alienage has been removed by statute, and the real estate of decedents does not escheat because their only relatives are aliens. It is the general rule that a proceeding known as "inquest of office" must be instituted in behalf of the state, in order to vest in it the title to a decedent's realty. But this is not required in some of the states.

ESCHELLES, LES, a village in Savoy (formerly a Sardinian, now a French state), is situated on the Guier, 12 m. s.w. of Chambéry. The valley beyond this village and on the road to Chambéry is blocked up by a huge limestone rock 800 ft. high, over which travelers formerly used to climb by means of ladders, and hence the name given to this village. Through this mass of limestone the public road now passes by means of a tunnel, which is 25 ft. high, of equal width, and 1000 ft. long. The tunnel was projected and commenced by Napoleon I., and finished in 1817 by the king of Sardinia.

ESCHENBACH, WOLFRAM VON, a celebrated poet of the middle ages, was b. in the second half of the 12th c., of a noble family, which derived its name from the village of Eschenbach near Ansbach. He received the honor of knighthood at Henneberg, and passed his life in knightly fashion. In 1204, he came to the court of Hermann, landgraf of Thuringia, where he shone among the poets of the time, at the so-called Wartburg-war (a rivalry of the German minstrels held at Wartburg in 1206 or 1207). Hermann's successor, Ludwig the pious, appears to have shown E. little favor, in consequence of which he withdrew from the Thuringian court towards the close of his life. He died some time between 1219 and 1225, and was buried in his native village. E.'s poems are partly original, and partly fashioned after French and Provençal models. His rich fancy, deep sentiment, and vivid power of representation, as well as his elegant mastery of language and versification, give something of an epic character to his works, the principal of which are *Parival*, composed before 1212, *Wilhelm von Orange*, and *Titurel*. Besides these, we have several love-songs of his. E. exercised an important influence on his time, but subsequently was almost forgotten; and it is only recently that he has been restored to his place of honor. The first critical edition of his works was that by Lachmann (Berl. 1833). They were translated into modern German by San-Marte (3 vols., Magdeb. 1836-41), and with greater accuracy, though with too slavish literalness, by Simrock (2 vols., Stuttg. 1842).

ESCHENMAYER, KARL ADOLF AUGUST VON, 1768-1852; b. Würtemberg; teacher of practical philosophy at the university in Tübingen, 1818-36; author of many works on philosophy, some of which were directed against the theories of Hegel and against the *Life of Jesus*, by Strauss. He carried a strong tendency to mysticism into his physical researches, and took a deep interest in the phenomena of animal magnetism, becoming at last a devout believer in demoniacal and spiritual possession.

ESCHER, JOH. HEINR. ALFRED, a distinguished Swiss statesman, was b. at Zurich, 20th Feb., 1819, and studied at Bonn and Berlin. In 1842, he was created doctor of law at Zurich; and spent the two following years in Paris, devoting his attention chiefly to studies connected with Roman law. On his return to Zurich, E. became a lecturer in the high school, the subject of his lectures being chiefly the political law of the Swiss confederacy. In 1844, he was elected member of the great council of the canton, and was thus drawn into the arena of practical statesmanship. Even at that early period, his sentiments were decidedly liberal. In Jan., 1845, along with six others who shared his opinions, he published the famous summons to the popular assembly in Unterstrass for the expulsion of the Jesuits. His election into the council of the interior in 1845, and into the council of education in 1846, opened a wide field for his administrative talents in his native canton. The reorganization of the schools in the canton of Zurich, according to the demands of the time, is chiefly his work. In Dec., 1847, he became president of the great council; and in his opening speech, recommended the complete reform of the confederacy, and the greatest possible centralization. In 1848, he was sent as a deputy to the federal diet; and, along with M. Münzinger, was charged with the negotiations entered into between Switzerland and Austria, in regard to the canton of Tessin. In Dec. of the same year, E. became president of the newly elected council of regency. Since that time, his energies have been chiefly directed to education, the reorganization of church policy, and the promotion of railway enterprise and banking institutions in Switzerland. He became president of the national council in 1849, and held the post of vice-president in 1856-57, and 1861-62. He died 1882.

ESCHOLTZ BAY, a portion of the Arctic ocean in Alaska, Ter., forms the innermost part of Kotzebue sound, the first great inlet to the n.e. of Behring's strait. It is about long. 161° w., being barely on the outside of the polar circle. It is worthy of notice chiefly on account of its fossil remains, which, though common on the northern coast of Siberia, are comparatively rare on that of the new continent.

ESCHSCHOLTZIA, a genus of plants of the natural order *papaveraceæ*, of which *E. Californica*, and other species, natives of California, have now become very common in our flower-gardens, making a showy appearance with their large deep yellow flowers. The genus is remarkable for the calyx, which separates from the dilated apex of the flower-stalk, being thrown off by the expanding flower, and much resembling in its form the extinguisher of a candle.

ESCHWEGE, a t. of Prussia, in the province of Hesse-Nassau, is situated on the left bank of the Werra, 25 m. e.s.e. of Cassel. It consists of an old and new town, and a suburb; is surrounded with walls pierced by six gates; and is well built. The only building of note is the castle, which was long the residence of the landgrafs of Hessen-Rotenberg. E. has manufactures of woolen and linen fabrics, etc., also some trade in fruit and victuals. Pop. '90, 9776.

ESCHWEILER, a t. of Rhenish Prussia, in the circle of Aachen, and 9 m. e.n.e. from the city of Aachen (Aix-la-Chapelle), is a station on the railway between Aix-la-Chapelle and Cologne, and stands at the confluence of the Inde and Dente. It has extensive manufactures of ribbons, woollens, canvas, needles, iron-wire, and machinery, also of wax-cloth, lace, glass, vitriol, and vinegar. In the vicinity are mines of zinc and lead. Pop. of commune '90, 18,119.

ESCOBAR Y MENDOZA, ANTONIO, 1589-1669; a Spanish casuist descended from the illustrious house of Mendoza; educated by the Jesuits and a member of the order. He was a preacher for 50 years, delivering sometimes two sermons in a day. His principal works were on casuistry and on Scriptural commentary. His casuistry was severely criticised in the *Provincial Letters* of Pascal, and ridiculed by Boileau, Molière, and La Fontaine, and the name Escobar became a synonym in France for extreme laxity in moral principle.

ESCORT. See CONVOY.

ESCU DO DE VERA GUA denotes at once a river and an island on the Atlantic side of Central America—the latter being at the mouth of the former. They are situated a little to the e. of the boundary between New Granada and Costa Rica. The island is in lat. 9° n., and long. 81° 30' w.; and the river, being only 15 m. long, derives its importance, if any, from the narrowness of the belt which here separates the two oceans.

ESCURIAL (the correct title is EL REAL SITIO DE SAN LORENZO EL REAL DE ESCORIAL), a famous monastery of New Castile, in the province of Madrid, and situated 30 m. n.w. of the town of that name. This solitary pile of granite has been called the eighth wonder of the world, and at the time of its erection surpassed every building of the kind in size and magnificence. It owes its origin (at least, so it is said) to an inspired vow made by Philip II. during the battle of St. Quentin. On that occasion, he implored the aid of St. Lorenzo, on whose day, 10th Aug., 1557, the battle was fought; and vowed that, should victory be granted to him, he would dedicate a monastery to the saint. The E. is built in the form of a gridiron, in allusion to the instrument of St. Lorenzo's martyrdom, and forms a huge rectangular parallelogram 744 ft. from n. to s., and 580 ft. from e. to w., and divided into long courts, which indicate the interstices of the bars. Towers at each angle of this parallelogram represent the feet of the

gridiron, which is supposed to be lying upside down; and from the center of one of the sides, a range of building abuts, forming the royal residence, and representing the handle. The E. was begun in 1563, and finished in 1584, and was intended to serve as a palace, mausoleum, and monastery. It has a splendid chapel with three naves, 320 ft. long, and 320 in height to the top of the cupola. The *pantheon*, or royal tomb, is a magnificently decorated octagon chamber, 36 ft. in diameter by 38 ft. high, in the eight sides of which there are numerous black marble sarcophagi. Kings only and the mothers of kings are buried here. The E. is an immense building; it is stated that it has 14,000 doors and 11,000 windows, and its cost was 6,000,000 ducats. Its library, previous to the sack of the E. by the French in 1808, contained 30,000 printed and 4,300 MS. volumes, mainly treasures of Arabic literature, of which a catalogue, but not a good one, was drawn up by Casiri in his *Bibliotheca Arabico-Hispanica* (2 vols., Madrid, 1760-70). They were, however, at that time removed to Madrid; and on being sent back to the E., it was discovered that the library consisted only of about 20,000 volumes—a third of the whole having been lost. The French also plundered the place of its valuable collection of coins, medals, and pictures. On Oct. 2, 1872, the E. was struck by lightning, and partially burned. The E. is saved from going to ruin by grants of public money, which are occasionally made.

ESCUTCHEON, in heraldry, is synonymous with shield (q. v.).

ESCUTCHEON OF PRETENSE, or **INESCUTCHEON**, is a small shield placed in the center of the larger one, and covering a portion of the charges on the latter, in which a man carries the arms of his wife when she is the heiress of her family. It is said to be carried *surtout*, or over-all. Sometimes also a shield over-all is given as a reward of honor; thus, the earl of Stirling did bear two coats quarterly, and over all an inescutcheon of Nova Scotia, because he was the first planter of it.—*Mackenzie, Heraldry*, p. 82.

ESDRAË'LOH, a great plain in Palestine, separating the mountain ranges of Galilee from those of Samaria. It forms a triangle between Nazareth in the n., a pass opening toward Akka in the w., and Jenin, the ancient Eugeanium, in the south. The watershed extending from Nazareth to Jenin, about 15 m., may be considered the base of the triangle, and divides the lands drained by the Jordan from those watered by the Kishon. The Galilean hills, forming the n. boundary of the plain, extend from Nazareth w. 12 m., and there draw near the Carmel range, forming a narrow pass by which the Kishon finds egress toward the sea. The Carmel, or Samaria, range extends from this pass s. e. 18 m. to Jenin. The e. boundary rises at times into high hills, the most important of which is Mt. Gilboa. The plain is sometimes called the valley of Jezreel. This plain of E. has in all history been a battle-field. It was the scene of important battles between the Israelites and their enemies, among them the triumph of Barak and the defeat of Saul and Josiah. Here the Egyptians and the Assyrian hosts met in repeated struggles, and in later times it appears in the wars of Napoleon. In the sublime imagery of the book of the Revelation, this plain appears as the scene of the last great struggle between the powers of good and evil.

ESDRAS, BOOKS OF. The word *Esdra*s is the Greek form of Ezra, and indicates that the books so named do not exist in Hebrew or Chaldee. In the Vulgate, the first book of Esdras means the canonical book of Ezra; and the second, the canonical book of Nehemiah; whilst the third and fourth are what we call the first and second books of Esdras. But in the Vatican and other editions of the LXX., what we call the first book of Esdras comes first, and is followed by the canonical book of Ezra, which is termed the *second* book of Esdras. In all the earlier editions of the English Bible the order of the Vulgate is followed. The Geneva Bible was the first to adopt the classification now used, according to which Ezra and Nehemiah give their names to two canonical books, and the two apocryphal become first and second Esdras. As regards the *first* book of Esdras, it is for the most part a transcript—and not a very accurate one—of Ezra and a portion of Nehemiah, together with the two last chapters of 2d Chronicles. It is impossible to ascertain anything regarding its age or authorship. Josephus quotes it extensively in his *Antiquities*, even when it contradicts *Ezra* proper, a fact which indicates that it was highly valued by the Jews. It may perhaps be interesting to notice that the hackneyed phrase, *Magna est veritas et prevalebit* (truth is great, and will prevail), is taken from the 41st verse of the 4th chapter of this book. The *second* book of Esdras, or Revelation of Esdras, is wholly different in character from the first, and it has even been doubted whether it is the work of a Jewish or of a semi-Christian writer. Lawrence and Hilgenfeld argue for its being composed 28-25 B.C.; Lücke, shortly after the death of Cæsar (44 B.C.); while Gfrörer, Bauer, and Wieseler assign it to a period as late as the reign of Domitian (81-96 A.D.). The opinion which has the weightiest evidence in its favor is, that the book was originally the composition of a Jew, but that it has been largely interpolated by Christian writers. The book was probably written in Egypt, and forms part of what has been called the "Apocalyptic Cycle" of Jewish literature (see REVELATION OF ST. JOHN). It consists of a series of angelic visions and revelations made to Ezra, regarding the mysteries of the moral world, and the final triumph of the righteous, who, however, are to be but "a very few." The descriptions are occasionally very striking, and even sublime, and if the doctrinal portions

contain the original views of a man living before the apostolic era, the source of the Pauline phraseology can in part be discovered.

ESENEBECKIA, a genus of trees of the natural order *diosmaceæ*. The bark of *E. febrifuga* is said to be equal in its effects to Peruvian bark. It is a tree 40 ft. high, a native of the s. of Brazil.

ESK (Gaelic, *uisg*, water), the name of several small Scotch rivers. The Dumfriesshire Esk is formed by the confluence of the Black and White Esk, which rise on the borders of Selkirkshire, near Ettrick Pen, the center of the southern Highlands, and run each 10 m. s.s.e. The united stream runs 35 m. s., and forms for a mile the boundary between Scotland and England. For the last 8 m. it runs s.s.w. in Cumberland, and finally falls into the head of the Solway firth. It flows in a Silurian, carboniferous, and Permian basin, through some charming scenery, past Langholm, Canobie, and Longton. The upper part of the valley of this E., which is wild and pastoral, is called Eskdale Muir.—The Edinburghshire North and South Esk rise in the n. of Peeblesshire, between the Pentland and Moorfoot hills, and both run n.n.e. through a beautiful tract in the e. of Edinburghshire, the n. branch, 20 m. long, passing Roslin and Hawthornden and the s. branch 15 m. long. The two branches unite in Dalkeith park, and run 3 m. n. into the firth of Forth at Musselburgh. The basin of the two streams is chiefly carboniferous.—The Forfarshire North and South Esk. The North Esk rises in the Grampians, in the n. of the county, and runs 25 m. s.e. into the sea, 4 m. n. of Montrose. At Ganachy bridge it runs half a mile through a sandstone gorge 20 to 30 ft. deep. In the lower half of its course it divides Forfarshire from Kincardineshire. The South E. rises in the Grampians of the w. of Forfarshire, and runs 40 m. s.e. and e., crossing the valley of Strathmore. It passes Brechin, and ends in the tidal basin or lagoon of Montrose. The basins of both consist of gneiss, mica-slate, clay-slate, and old red sandstone.

ESKIMO. See ESQUIMAUX.

ESKI-SA'GRA, or STARA-ZAGORA, a town of eastern Roumelia, is situated at the southern base of the Balkan mountains, 70 m. n.w. of Adrianople. In the vicinity are numerous gardens and orchards, and also several mineral springs, which are in great repute. Silk and wool are produced. Pop. 15,000 to 20,000.

ESLA, a river of Spain, and an important affluent to the Douro, rises in the province of Palencia, Old Castile, from the southern base of the Asturias mountains, 10 m. n.w. of the town of Valleburon. Throughout the whole of its course, it flows s.w., and joins the Douro 15 m. below the town of Zamora. It is 125 m. in length. Its waters, which are joined by numerous streams, are well stocked with fish.

ESMARCH, JOHANNES FRIEDRICH AUGUST, b. Tönning, Schleswig-Holstein, 1823; studied medicine at Kiel and Göttingen, and in the Danish war of 1848 served as lieutenant, as assistant surgeon, as chief physician of the citizens' hospital at Flensburg, and lastly as adjut. of Dr. Stromeyer, whose daughter he married. He became prof. and director of the hospital at Kiel, 1857, and during the Schleswig-Holstein war, 1864, and the Franco-Prussian war, 1870, held high official positions. He is the greatest living authority on gunshot wounds; has originated valuable improvements in barrack hospitals, ambulances, etc.; is the inventor of the bloodless method of operating on the extremities, which he has since combined with the antiseptic method of Lister; and has published *Beiträge zur Praktischen Chirurgie*, 1853-60; *Verbandplatz und Feldlazarett*, 1871; *Ueber Künstliche Blutleere bei Operationen*, 1873; *Die Erste Hilfe bei Plötzlichen Unglücksfällen*, etc. His second wife was the Princess Henrietta of Schleswig-Holstein, aunt of the Empress Victoria of Germany.

ESMERALDA, a co. in s.w. Nevada, on the California border, intersected by Walker river, and containing Walker lake, a large body of water having no known outlet; 8540 sq. m.; pop. '90, 2148. There are gold and silver mines, but little agriculture, the land, where not mountainous, being arid plains. Co. seat, Aurora. The great salt basin, in this county, is covered with pure salt, and is 16 m. long and 3 m. wide.

ESMERALDAS (signifying *emerald* in Spanish) denotes a river, a town, and a province, all in the state of Ecuador (q. v.) in South America.—1. The river rises near the city of Quito, and enters the Pacific after a course of 110 m., in lat. 1° 5' n., and long. 79° 40' w.—2. The town stands 10 m. from the mouth of the river, containing about 4,000 inhabitants.—3. The province, watered by the above-mentioned river, occupies the n.w. of Ecuador; is mostly covered with forests; and produces cacao and tobacco. Pop. 15,000.

ESNÉ, ESNA, or ESNEH, the hieroglyphic *Sen*, and the Greek *Latopolis* or *Lattónpolis*—the city of the latus fish or *latus nobilis*, from the fish there worshiped—is a thriving but badly built town of Upper Egypt, and is situated on the left bank of the Nile, in lat. 25° 15' north. It contains about 12,000 inhabitants, many of whom are Copts, and has some manufactories of fine cotton, shawls, and pottery. It is an entrepôt for the Sennar caravans. There are famous ruins at E., which consist of a sandstone temple, with a portico of four rows of six columns, which appears to have been founded by Thothmes III., whose name is seen on the jambs of a door. The temple, however, seems to have been restored or principally constructed by Ptolemy Eurgetes (246-222 B.C.), and the pronaos was erected in the reign of the emperor Claudius (41-54 A.D.), and completed

in that of Vespasian. The interior is of the date of Trajan, the Antonines, and Geta, whose name, erased or replaced by that of Caracalla, is there found. The great temple was dedicated to Chnumis, Satis, and Har-Hek. It has a zodiac like that of Dendera, formerly thought to be of the most remote antiquity, but now known to be no older than the Romans. A smaller temple with a zodiac, erected in the reign of Ptolemy Eurgetes, formerly stood at E'Deyr, $2\frac{1}{2}$ m. n. of E., but it has been destroyed. At E. is also a stone quay, bearing the names of M. Aurelius. This city was the capital of a nome, and the coins struck in it in the reign of Hadrian, 127-28 A.D., represent the fish latos.—Champollion, *Not. Descr.* p. 283; Wilkinson, *Mod. Egypt*, ii. p. 268; Tochon d'Anney, *Médailles*.

ESOCIDÆ, a family of malacopterous fishes, which is now regarded as including only the pikes (q.v.), but in which the flying fishes (*exocoetus*) and other fishes, now constituting the family *scomberesocidæ* (q.v.), and of the order *pharyngognaths*, were until recently included.

ESOP. See *Æsop*.

ESOPUS, a town in Ulster co., N. Y., bounded n.w. by the Wallkill river, and containing the manufacturing village of Port Ewen. Pop. 4659.

ESOPUS WAR, the name usually given to a war between the Indians and the Dutch settlers at Esopus in Ulster co., N. Y., which began in the summer of 1658 and lasted intermittently until 1664. In the former year some Indians, employed as field-hands by the Dutch, had become drunk and boisterous, and were fired upon by the farmers. This gave rise to a series of bloody reprisals on the part of the Indians, the most serious of which was the destruction of the village of Wietwyck, when 40 women and children were carried off as prisoners and 21 men were slain.

ESOTERIC (Gr.) is a term derived from the ancient mysteries, in which it was applied to those doctrines that were designed for the initiated, in contradistinction to those that were imparted to the uninitiated, which were termed *exoteric*. It is now used in various relations of an analogous kind.

ESPALIER, a term borrowed from the French, and signifying a railing on which fruit-trees are trained as on a wall. Such railings are very variously constructed—sometimes of wood, sometimes of iron, sometimes of upright rails held together by a horizontal rail at top, sometimes chiefly of horizontal rails with upright posts for their support. Espaliers may be very conveniently and cheaply made of strong iron wire, sustained by upright iron or wooden posts, as in ordinary wire fences. They vary in height from 4 to about 8 ft., according to situation and the size of the garden. They have the advantage of securing the fruit in a great measure from the effect of winds, which often shake off great part of the crop of standard trees whilst still unripe: and from the full exposure to sun and air, excellent fruit is produced, although there is no reflected heat as from a wall, which is therefore still superior.

ESPARTEÑO, JOAQUIN BALDOMERO, ex-regent of Spain, count of Luchana, duke of Vittoria, etc., was b. 27th Feb., 1792, at Granatula, in La Mancha (Ciudad Real), where his father, Antonio Espartero, followed the occupation of a cartwright. E. was intended for the ecclesiastical profession, and in 1806 went to the university of Almagro, but two years later, on the invasion of Spain by the French, he entered the sacred battalion (*battalion sagrado*), so called from being composed almost entirely of students. After the close of the war of independence in 1814, he went to South America, where he fought against the insurgents; but after the victory gained by Bolivar at Ayacucho, Dec. 9, 1824, had put an end to the Spanish rule on the continent of America, E. returned to Spain. In 1832, he declared himself openly in favor of the succession of the daughter of Ferdinand VII.; and on the breaking out of the civil war after the king's death, he soon rose to the rank of lieutenant. In Aug., 1836, he succeeded in saving the city of Madrid, and became successively gen.-in-chief of the army in the n., viceroy of Navarre, and capt.gen. of the Basque provinces. When the army of Don Carlos appeared before Madrid on the 12th Sept., 1837, E. had again the glory of saving the capital. His successful campaign of 1839, which resulted in the expulsion of Don Carlos from Spain, procured him the title of grandee of Spain, and duque de la Vittoria y de Morella. In 1840, the queen-mother, Christina, was compelled to resign her office of regent, and on the 8th of May, 1841, E. was appointed by the Cortes to supply her place until the queen (Isabella) should have reached her majority. E. guided the helm of the state with energy, firmness, and ability; but in 1843 an unscrupulous and unprincipled combination of parties naturally inimical to each other, the republicans and the moderados, brought about his fall. E. sailed for England, where he resided for four years. In 1847, he returned to Spain, and lived quietly at Logroño till 1854, when the wretched despotism and profligacy with which the name of Christina is associated, caused an insurrection of the people, and compelled the queen-mother to leave the kingdom. E. was again called to the head of the government, and conducted the affairs of the nation for two years; but in July, 1856, he was supplanted by gen. O'Donnell. In 1857, he resigned his dignity as senator, and after that time rarely took part in politics. After the revolution of 1868, which resulted in the expulsion of Queen Isabella, E. gave his full and hearty adhesion to the provisional government, though he

took no part in their proceedings. In 1870, E. was induced to become a candidate for the throne of Spain; but withdrew in June of the same year, alleging his age and the division of parties as excuse. In 1875, he adhered to King Alfonso. He died Jan., 9, 1879.

ESPERANTO, an artificial language, named from its inventor, a Spanish scholar, who first published it in 1890. It differs from Volapük (q.v.) in that its vocabulary is constructed upon such words only as are common to *all* European languages. Hence it will at the outset be easy of acquisition, and will not appear uncouth or strange to any. The following comparison will serve to illustrate the difference between English, Volapük, and Esperanto.

In English.—"The international language should be comprehensible to the whole educated world; but no man on the earth, except the Volapükist, would comprehend even the word 'Volapük.'"

In Volapük.—"Pük bevünetik pakapälom fa vol lölik pekulivöl; abu men nonik tala sesumü volapükels, kapalom püki lekanix 'Volapük.'"

In Esperanto.—"La lingvo internacia estas komprenita de la tuta mondo edukita; sed nenia homo sur la tero eksklusive la volapükistoj komprenas la artan lingvon 'Volapük.'"

ESPINASSE, JULIE JEANNE ELEONORE DE L', one of the most fascinating women of her time, and one who combined sparkling gifts with a heart susceptible of the strongest affections, was b. at Lyons, 19th Nov., 1732, and was the illegitimate daughter of a Mme. d'Albion. After the death of her mother, Mlle. de l'E., who had received an excellent education, went to live at the house of her brother-in-law, the marquis de Vichy-Chamroud, in whose family she held the position of *gouvernante*. In 1752, she left her brother-in-law's house, and went to Paris in the quality of *demoiselle de compagnie* to the marquise Du Deffand (q.v.). The two ladies lived together for a time most agreeably, until it became evident that the charms of the young and beautiful *demoiselle* had enlisted on her side the admiration of the circle in which Du Deffand had formerly been the chief attraction. Even D'Alembert, the famous encyclopédist, who hitherto had been the most constant admirer of Du Deffand, now manifested an entire devotion to the younger and more fascinating Espinasse. A rupture between the ladies was the consequence. The friends of E., however, obtained for her, through the duc de Choiseul, an annuity from the king. It is said that D'Alembert sought her hand in vain. She died 23d May, 1776. Her *Lettres*, etc. (Paris, 1809), bear witness to her remarkable cultivation.

ESPIRITU SANTO, besides having been long applied by the Spaniards to their imaginary continent in the southern hemisphere, denotes various actual localities.—1. E. S. is a small maritime province of Brazil, extending in s. lat. from 18° 30' to 21° 20', and lying immediately to the n. of the metropolitan province of Rio Janeiro. This province contains also a town and a bay of its own name.—2. E. S. is the largest and most westerly island of the New Hebrides, being in lat. 15° s., and long. 167° east. It is said to measure 80 m. by 40.—3. E. S. is a cape of Tierra del Fuego, in lat. 52° 38' s., and long. 68° 37' west.—4. E. S. is a considerable town near the center of Cuba. It contains about 9,982 inhabitants, fully one half being whites.—5. E. S. is a bay of the gulf of Mexico, forming part of the almost continuous back-water of Texas. It is in lat. 28° 30' n., and long. 97° 30' west. Towards the open sea, it is breasted by Matagorda island, and on the side of the mainland, it receives the Guadaloupe.

ESPLANADE (in fort.) is the open space intentionally left between the houses of a city and the glacis of its citadel. It requires to be at least 800 paces broad, that the enemy, in case of his getting possession of the town, may not be able to assail the citadel under cover of the nearest houses. For this purpose, the citadel must command the E., and be able to send a direct fire into the streets opening upon it. In old works on fortification, the term is often applied to the glacis of the counterscarp, or the slope of the parapet of the covered way towards the country.

ESPOUSAL. 1. Among the Jews. the ceremony of betrothal or of engagement to be married. It was entered into a year or more before marriage, and consisted in giving and receiving before witnesses, either a piece of silver as a pledge, or a written contract wherein the bridegroom bound himself to give a certain sum as a portion to the bride. From the time of espousal the woman was considered as the lawful wife of the man to whom she was betrothed. 2. In the early Christian church also, a ceremony of espousals preceded marriage. The preliminaries consisted in a mutual agreement between the parties that the marriage should take place within a limited time, confirmed by certain donations as the earnest of marriage, and attested by a sufficient number of witnesses. The free consent of parties contracting marriage was required by the old Roman law and by the code of Justinian. The gifts bestowed were publicly recorded. The dowry settled on the bride was stipulated in public instruments under hand and seal. The ring was given at the betrothal rather than at the actual marriage. The use of the marriage ring has been traced to the 10th c., its recognized place being then as now on the woman's fourth finger. The witnesses present, friends of both parties, were usually ten in number. The espousal, as incorporated with the wedding-rite, is plainly traceable in the usages of the Roman, Anglican, and other churches at the present day.

ESPRIT DE CORPS (Fr.), the animating spirit of any body; loyal attachment to the body or order of which one happens to be a member, as to the army or the bar.

ESPRIT D'IVA, an aromatic liquor made in Switzerland, from a plant called *GENIPI* (*achillea moschata*, or *ptarmica moschata*; see *ACHILLÆA*). Like the *Swiss tea* made from the same plant, it possesses sudorific properties.

ESPRITS FORTS (advanced thinkers, bold spirits), the name assumed by the French school of writers in England termed freethinkers (q.v.), and including Voltaire, Diderot, Helvétius, D'Alembert, and their contemporaries, who were the precursors of the revolution. While the English freethinkers aimed at securing freedom of religious speculation merely, and did not seek the violent substitution of a system based upon their own views for the existing order, the French *esprits forts* held a distinctly aggressive position outside of all religious confessions, vigorously opposed the despotism of church as well as of state, and were, in fine, propagandists of the most radical sort. This is shown by the vehemence and bitterness of their language, and by the rigidity of their philosophical system. Skeptical of the value of human feeling as a guide, they desired the authority of pure reason alone to be recognized, and the supremacy of the intellect to be everywhere acknowledged. Their influence was extensively felt, and many of the doctrines which they inculcated bore fruit in the revolution. See *AGE OF REASON*.

ESPY, JAMES POLLARD, one of the most original and able meteorologists of the present century, was the son of a farmer in Washington co., Penn., where he was b. May 9, 1785. He received a superior education, and, during the earlier part of his career, was one of the best classical and mathematical instructors in Philadelphia. E.'s attention was first strongly turned to science by the writings of Dalton and Daniell on meteorology. After some time, his enthusiasm became so great, that he resolved to give up teaching, and to rely for the means of prosecuting his meteorological researches upon his slender savings and the success of his lectures on the subject, which, fortunately, turned out to be far more attractive than the average of popular lectures. His first course was delivered before the Franklin institute of Pennsylvania. E.'s theory of storms (with which his name is specially connected) drew general attention to itself, especially in the United States. See *STORMS*. A memoir on this subject gained for him, in 1836, the Magellanic premium of the American philosophical society of Philadelphia. In 1841, appeared his work on the *Philosophy of Storms*, regarding which the report of the *Académie des Sciences* (Paris) says, "that the theory on which it is based alone accounts for the phenomena. . . . In a word, for physical geography, agriculture, navigation, and meteorology, it gives us new explanations, indications useful for ulterior researches, and redresses many accredited errors." Later in his life, E. became professor in the Philadelphia high school, and afterwards in the Franklin institute of that city. He traveled extensively through the United States, lecturing on his favorite theory of storms, and studying the laws of climate, until he acquired the popular title of the "storm-king." After the organization of the Smithsonian institution at Washington, he was commissioned by Dr. Henry, its superintendent, to pursue his researches. It was in the halls of the Smithsonian that his experiments on the rate of cooling of gases of different densities when expanded were made. The cooling effects of expansion on dry and moist air also formed the subject of nice experiments. The results of these experiments have thrown much light on the formation of cloud and rain, and the propelling power of winds. They afforded materials for his elaborate and valuable reports on meteorology, presented to the senate of the United States. Four of these reports were published at the expense of government. The last was issued in 1857, which embodies all his matured opinions on meteorological phenomena. He d. in 1860.

ESQUIMALT, an important seaport of British Columbia, Canada; on Vancouver island and the strait of San Juan de Fuca; 4 miles from Victoria. It has an extensive harbor capable of accommodating the largest vessels afloat; has been made the principal British naval station on the North Pacific, with navy yard, dry dock, hospital, and defensive works. The mean temperature for a term of five and a half years was 48.7° F.; the rainfall, 24.82 inches. Pop. '91, 200.

ESQUIMAUX, or *ESKIMOS*, is the name of a nation inhabiting the coasts of all the seas, bays, inlets, and islands of America n. of the 60° of n. lat.; from the eastern coast of Greenland, in long. 20°, to the strait of Behring, in long. 167° west. On the Atlantic, they are to be found along the entire coast of Labrador to the strait of Belleisle and down the e. side of Hudson's bay nearly as far as James's bay; while on the Pacific they reach as far as the peninsula of Alaska. They are also to be met with on the Asiatic side of Behring's strait, and, though few in number, may be regarded as the most widely spread nation in the world, occupying, according to Mr. Gallatin, not less than 5,400 m. of coast, without including the inlets of the sea. "The Eskimo," says Dr. Latham, "is the only family common to the old and new world—an important fact in itself, and one made more important still by the Eskimo localities being the only localities where the two continents come into proximity." Nothing, however, has as yet come out of a consideration of this fact in the way of tracing, with absolute certainty, a connection between the E. and any well-defined Asiatic race. The name itself, *Esquimaux* or *Eskimo*, does not help us in any such attempt, being from an Algonquin or Abenaki word, signifying "eaters of raw flesh." This is not the native name, for they call them-

selves "Inuit," or "people;" the Scandinavians of the 10th c. called them "Skroellin-gar," or "wretches;" while the seamen of the Hudson's bay ships designate them as "Seymos," or "Suckemos"—appellations, according to Richardson, "evidently derived from the vociferous cries of Seymo or Teymo with which the poor people greet the arrival of the ships." The E. are usually reckoned by ethnologists to belong to the Mongolian race, but Duponceau and Gallatin find a strong resemblance between them and the red Indians of North America, which is the view also taken by Prichard—the last mentioned regarding them as a kind of link between the northern Asiatic and American family of nations. Latham, on the other hand, pronounces them to be Mongolian in physiognomy, with flat nose, projecting cheek-bones, eyes often oblique, and skin more brown than red or copper colored; thus presenting a marked contrast to the North American Indians. Their language, however, is, he acknowledges, American in respect to its grammatical structure, being composed of long compound words, and regular, though remarkable, inflections. With respect to the complexion of the E., sir John Richardson is of a different opinion from any of these authors, describing it as nearly white, when relieved from the smoke and dirt with which it is usually incrustated. Many of the young women, he considers, may even be called pretty, when this operation has been performed. "The young men," he says, "have little beard; but some of the old ones have a tolerable show of long gray hairs on the upper lip and chin, which the red Indians never have, as they eradicate all stray hairs. The Eskimo beard, however, is in no instance so dense as a European one." In stature, the E. are usually represented as not being more than 5 ft. in height; but the authority just mentioned describes them as ranging from 5 ft. to 5 ft. 10 in., and even more. They are broad-shouldered, and, when seated in their boats, look tall and muscular, but, when standing, appear to lose some of their height, from the shortness of their lower extremities. The E. live usually throughout their long lines of coast in small villages, containing about five or six families each. The men occupy themselves entirely in hunting, while the women perform the domestic drudgery, which consists principally in preparing the food, of which both sexes consume a large quantity. This is almost entirely of an animal nature, but not without variety, embracing the reindeer, geese and other birds, the seal, walrus, salmon-trout, and various other kinds of fish. They are expert hunters and fishers, and, aided by their dogs, make considerable havoc among the arctic animal tribes. Where whales are common, Aug. and Sept. are devoted to the pursuit of these animals, and great joy is manifested when they capture any of them, as from the blubber of these they get their supply of oil for lights in the long winter season. Of vegetables, they scarcely taste any except in the autumn. "Carbon is supplied to the system by the use of much oil and fat in the diet, and draughts of warm blood from a newly-killed animal are considered as contributing greatly to preserve the hunter in health." The habits of the E. are filthy and revolting in the extreme. A great part of their food is consumed without any attempt at cooking it, and they drink the blood of newly-killed animals as the greatest delicacy that could be offered them. In the short summer, those who can afford it live in tents; but in the winter they all equally live in snow-huts, the stench of which, from the offal with which they are stored, and the filthy oil that gives them light, makes them insupportable to the European. The dress of both sexes is nearly the same, consisting of the skins of animals, reindeer, birds, and even fish—whatever conduces most to warmth, without much regard to appearance; but in their winter abodes they usually wear nothing except trousers. Their religion consists principally in superstitious observances, but they believe, we are told, in two greater spirits, and many lesser ones. The Moravian mission in Greenland, commenced by the benevolent Hans Egede (q.v.), in 1721, has succeeded in converting many of them to Christianity; and they are represented by the missionaries to be a mild and teachable people, easily led by kindness to distinguish between what is morally right and wrong. Where the missionaries, however, have not penetrated, Arctic voyagers generally speak of them as honest among themselves, but incorrigibly dishonest and prone to lying and exaggeration with strangers.—See Dr. Rink's *Tales and Traditions of the Eskimo*. See *ILLUS.*, NORTH AND SOUTH AMERICA, vol. I.

ESQUIMAUX DOG, a kind of dog extensively spread over the most northern regions of North America and of eastern Asia; large, powerful, with long rather curling hair, tail much curved over the back and very bushy, short and pointed ears, and somewhat wolf-like aspect. These dogs are much used for drawing sledges. They are very sagacious, docile, and patient. The color is generally black and white, brown and white, or dingy white.

ESQUIN TLA, or **ESCUINTLA**, a t. of the state of Guatemala, Central America, 25 m. s. from Guatemala, on the river Michatoya, which falls into the Pacific ocean. It has a fine church. Pop. 6,000, consisting in great part of Indians.

ESQUIRE (Fr. *escuyer*. a shield-bearer, from Lat. *scutum*, a shield). The E. in chivalry was the shield-bearer or armor-bearer to the knight, and hence was called *armiger* in Latin. He was a candidate for the honor of knighthood, and thus stood to the knight in the relation of a novice or apprentice, pretty much as the page did to him. In this capacity he was spoken of as a bachelor, just as the knight-bachelor came latterly to be distinguished from him who had already attained to the higher honors of

chivalry. When fully equipped, each knight was attended by two esquires. The E. was a gentleman, and had the right of bearing arms on his own shield or escutcheon, which is surmounted by a helmet placed sideways, with its visor closed, to distinguish him from a knight or nobleman. He had also the sword, the emblem of chivalry, though he was not girded with the knightly belt. His spurs were silver, to distinguish them from the golden spurs of the knight; and when the king created esquires of old, it was by putting silver spurs on their heels, and collars of SS round their necks. Those who received this honor directly from the sovereign were in general the esquires for the king's body, or those whose duty it was to attend him in his capacity of a knight; an office now nearly obsolete. Tenants of the crown who held by knight's service were a class of feudal esquires generally supposed to correspond to the simple *ritters* or knights of Germany, as opposed to the *ritters* who were *geschlagen* or dubbed, inasmuch as these English esquires were entitled to claim the rank of knight-hood. Though the title of E. has now come to be given without discrimination to all persons above the rank of a tradesman or shopkeeper, the following seem to be those whose claim to it stands on the ground either of legal right or of long-established courtesy: 1. All the untitled sons of noblemen; 2. The eldest sons of knights and baronets; 3. The sons of the younger sons of dukes and marquises, and their eldest sons. All these are esquires by birth. Then there are esquires by profession, whose rank does not descend to their children; and esquires by office—e.g., justices of the peace—who enjoy the title only during their tenure of office.

ESQUIROL, JEAN ETIENNE DOMINIQUE, one of the greatest physicians for the insane of modern times, was b. at Toulouse, 4th Jan., 1772. He served in the military lazaretto at Narbonne in 1794, obtained his degree of doctor in 1805, and was appointed physician to the Salpêtrière at Paris in 1811. After 1817, he delivered clinical lectures on the diseases of the mind, and their cures; in 1818, his exertions secured the appointment of a commission, of which he became a member, for the remedy of abuses in mad-houses; in 1823, he became inspector-general of the university; and in 1825, first physician to the *Maison des Aliénés*. In the following year, he was also appointed principal physician of the private lunatic asylum at Charenton, which he had organized with admirable skill. At the July revolution, he lost all his public offices, and withdrew into private life. He died 12th Dec., 1840. E. combined, in a truly rare and wonderful manner, the qualifications requisite for a physician of the body and a physician of the mind. By his humane and moral treatment of the insane, he often effected the happiest cures. His writings embrace all the questions connected with the treatment of insanity. E. also paid great attention to a very important subject, viz., the construction of suitable buildings for the insane; and most of the modern lunatic asylums in France, such as those of Rouen and Montpellier, have been built according to his advice. His most important work is *Des Maladies Mentales considérées sous les Rapports Médical, Hygiénique et Médico-légal* (1838).

ESQUIROS, HENRI ALPHONSE, a poet and romancist of France, a representative in the national assembly, was b. at Paris in 1814. He made his *début* as an author in 1834, when he published a volume of poems, entitled *Les Hirondelles*, which, although highly praised by M. Victor Hugo, had but a very limited sale. *Les Hirondelles* was followed by two romances, *Le Magicien* (1837) and *Charlotte Corday* (1840). About this time he also published a philosophic and democratic commentary on the life of Christ, under the title of the *Evangile du Peuple* (1840). For the publication of this work, E. was prosecuted, and sentenced to 8 months' imprisonment and to a fine of 500 francs, 30th Jan., 1841. In the same year he published his *Chants d'un Prisonnier*. He also wrote three little works between 1841 and 1842—these were *Les Vierges Martyres*, *Les Vierges Folles*, and *Les Vierges Sages*. His *Histoire des Montagnards* appeared in 1847. After the revolution of Feb., 1848, E. was elected a member of the legislative assembly. Distinguished by his radical opinions, he was included, after the 2d Dec., 1851, among the number of members to be expelled; on which he retired to England. His *La Vie Future au Point de Vue Socialiste* appeared in 1857; and his *La Morale Universelle*, his *L'Angleterre et la Vie Anglaise*, and his *La Neerlande et la Vie Hollandaise* in 1859. In 1869, he was returned to the corps législatif for the fourth circumscription of the Bouches du Rhône; and was appointed supreme administrator of that department by the government of the national defense in 1870. In 1871, he was returned to the national assembly, and in Jan., 1876, was made a member of the senate. He died 13th May, 1876, at Versailles.

ESS, HEINRICH LEANDER VAN, or JOHANN HEINRICH, 1772–1847; b. Westphalia; educated in the Dominican gymnasium of Warburg; a Roman Catholic priest from 1797 to 1812; and then professor of theology in the Marburg seminary. In 1807, he published the New Testament in German, but its circulation was forbidden by the pope. The next year he published a defense of his views, advocating the reading of the Bible by the people. In 1816, he published *What was the Bible of the first Christians?* and in 1818, *The Bible not a Book for Priests*. In 1840, he completed a German translation of the entire Bible. His library of 20,000 volumes, unusually rich in early editions of the con-

troversial works of the period of the reformation, was purchased after his death, and given to the Union theological seminary in New York.

ESSAAD-EFFENDI, MOHAMMED, a Turkish historian, was b. at Constantinople, 16th Dec., 1790. He was surnamed Sahaf-Zadeh, "son of the bookbinder," on account of his father having been president of a corporation of bookbinders and librarians. At the age of 18, he became a teacher; in 1825, he was appointed historiographer to the Ottoman empire. In 1831, the superintendence of the *Tutawin-i-wekaii* (Table of Events), the official journal of the empire, was placed in his hands. In 1835, he was employed by the late sultan Mahmoud on an embassy to Mohammed, the son and successor of the king of Persia. E. had also the titles of grand judge of Roumelia, inspector-general of schools, and member of the council of public instruction.

The works of E. comprise, among others, the *Uss-i-Tzafer* (the Establishment of Victory), a work which has been translated into French, and published by M. Causin de Perceval, with the following title: *Historic Summary of the Destruction of the Janizaries by the Sultan Mahmoud in 1826* (Par, 1833).

ESSAYS AND REVIEWS, by six clergymen and one layman of the Church of England (the Rev. Drs. Frederick Temple and Rowland Williams, Prof. Baden Powell, H. B. Wilson, Mark Pattison, Prof. B. Jowett, and Mr. C. W. Goodwin), were published in an 8vo. vol. in Mar., 1860. The book did not excite much attention at first, but having been severely censured for heterodox views by nearly all the bishops and many of the clergy, it created much excitement in 1861, and was condemned by convocation June 24, 1864. The ecclesiastical courts sentenced the Revs. R. Williams and H. B. Wilson to suspension for one year, and costs, Dec. 15, 1862; but on appeal the sentence was reversed by the judicial committee of the privy council, Feb. 8, 1864. The most remarkable among the works put forth in opposition (in 1862) are the *Aids to Faith*, edited by the bishop of Gloucester (W. Thomson, later archbishop of York), and *Replies to Essays and Reviews*, edited by the bishop of Oxford (Samuel Wilberforce). The appointment of Dr. Temple to the see of Exeter was much opposed on account of his essay in this collection.

ESSEG. See ESZEK.

ESSEN, a t. in Rhenish Prussia; situated between the Ruhr and the Emscher, 20 m. n.e. of Düsseldorf, stands in the midst of a rich coal and iron district. Its main importance lies in its activity as a manufacturing town; it has, however, an imposing cathedral, containing many curious reliquaries, crosses, etc. Owing to the productive coal mines, there are in the neighborhood extensive works for all sorts of manufactures in iron. The enormous works of Herr Krupp, the discoverer of the method of casting steel in very large masses, are at Essen. At them are manufactured many articles for peaceful purposes; but the gigantic steel guns which the Germans used with such terrible effect at the siege of Paris (1870-71) have made the name of Krupp world-renowned. The rapid increase in population raised the prices of all commodities consumed by the workmen, and to meet this evil the firm of Krupp established an immense system of co-operative stores which have been very successful. See CO-OPERATION. Pop. '95, 96, 163. Although the industrial activity of E. is only of recent growth, the town itself is very old, and can trace its origin to the famous Benedictine nunnery of the same name, founded in 873 A.D.

ESSEN, HANS HENRIK, Count, 1755-1824; born Sweden; educated in the State university; accompanied Gustavus III. in his travel abroad. He attended the king at the masked ball where the latter was assassinated by Anckarstroem, Essen having warned Gustavus of a probable attempt on his life. In later years, Essen was governor of Stockholm, governor-general of Swedish Pomerania and Rügen, and in 1807, commander of the Pomeranian army, distinguishing himself by the defense of Stralsund. Still later he was a member of the council, and ambassador in Paris. After the union of Sweden and Norway he was appointed governor of the latter country, and in 1817, governor-general of Scania.

ESSENCE, in philosophy (from Lat. *esse*, to be), is that which constitutes the particular nature of a being or substance, or of a genus, and which distinguishes it from all others. Locke's statement, that E. may be taken for the very being of a thing, whereby it is what it is, agrees with this definition. He makes, also, a distinction between nominal and real E., saying, for example, that the nominal E. of gold is the complex idea expressed by the word; and that its real E. is the constitution of its insensible parts on which its properties depend and which is unknown to us. In theology, Athanasius and other Greek writers distinguish *ousia* (essence or substance), denoting what is common to the Father, Son, and Holy Spirit, from *hypostasis*, denoting what is individual, distinctive, and peculiar. In modern writers, essence and substance are generally used as virtually synonymous, and representing, in any object, all that the human mind cannot know, while all that can be actually known is called quality or accident. As both terms are often vaguely employed, it is necessary, wherever they occur, first of all to ascertain the sense in which the writer intends them to be understood.

ESSENCE DE PETIT GRAIN is obtained by distillation from small unripe oranges, about the size of a cherry, and is used as a perfume in the same manner as *orange-flower water*.

ESSENCES are solutions of the essential oils in alcohol, and may be prepared (1) by adding rectified spirit to the odoriferous parts of plants, or to the essential oils, and distilling; or (2) simply by adding the essential oil to the rectified spirit, and agitating till a uniform mixture is obtained. Thus, the essence of lemons is merely a solution of the volatile oil of lemons in rectified spirit. This term is frequently used as synonymous with volatile oils.

ESSE'NES (*Essēnoi*, *Essaioi*), a small religious fraternity among the Jews, whose name and origin, as well as character and history, are alike involved in obscurity. Still, in the wide field of the history of the Semitic religions, there are not many subjects of inquiry of greater importance, or calculated to inspire a deeper interest. The E. bore one of the most momentous parts in the development of Judaism. Christianity stands in so close connection with them, that John the Baptist and Christ himself have been pronounced to have originally issued from their ranks. More surprising than all, out of Essenism, in the stage of Sabæism, has sprung Islam itself, and in this last development of its tenets and practices are still preserved some of its principal rites. It is but natural that from the days of the fathers to our own, an infinite number of writers, more or less qualified for the task, should have endeavored to throw light on this mysterious brotherhood, but with success far from satisfactory. The reason of this is obvious enough. Josephus, Philo, Pliny, Solinus, Eusebius, and the fathers generally, were considered the sources, and the only sources, from which the genuine history of this fraternity could be deduced. Of these, Pliny indeed has a geographical notice, which cannot be traced to either Philo or Josephus; but the rest have so evidently derived their shallow and contradictory accounts indirectly, and through corrupted channels, from those two writers, that they lose all claim to consideration. Of the two books of Philo in which information regarding the E. is contained, one (*De Vita Contemplativa*) is proved to have been written about three centuries after Philo's death by a Christian monk as a penegyric on ascetic monachism. The other (*Quod Omnis*) is, to say the least, of doubtful genuineness, and is, moreover, at variance with Josephus. As to Josephus himself, it is now pretty generally allowed that his E. stand in much the same relation to the historical E. as the ideal inhabitants of the *Germania* of Tacitus stand to the real Germans of his time. Strange that for so many centuries the real and genuine sources—the Talmudical writings—should never have been thought of. These, together with Josephus and Philo, Pliny, and the Arabians Macrisi and Abulfarag, will perhaps better enable us to form an idea, not only of the real state of this community, but, what is of no less moment, to trace the process by which they gradually arrived at their peculiar mode of life and worship. We need not remind the reader that we must strictly confine ourselves here to an epitome of facts and conclusions.

We have to premise, that exception must at the outset be taken to the opening statement of Josephus, that there were three different "sects" among the Jews: the Pharisees, the Sadducees, and the E.—a statement which has been copied and accepted from that day to the present. The Sadducees were a political party, nothing more or less, and, as a matter of course, held religious views antagonistic to, or rather they did not accept the traditions of, their adversaries, the Pharisees, who, again, forming as they did, the bulk of the nation, cannot rightly be called a *sect*. Least of all were the E. such. They were Pharisees of stronger convictions, and carried out the Pharisaic views with a consistency which made them ridiculous even in the eyes of their own mother-party (Sota, 26, a.); neither were they known by the names of E., this being a very late designation, derived either from a Chaldee word *sacha*, and meaning bathers, or baptists; or from *asa*, meaning healers. The Mishna, Beraitha, and Talmud speak of these advanced Pharisees in general as Chasidim (*Assidaioi*, pious men), Nazirim abstinentes), Toble Shachārith (hemerobaptists), Banai (builders), and Chaberim (friends). The Arabic book of *Maccabees* calls the E. simply *Assidaioi*, and Macrisi speaks of "Nazirs, Essenes, and Baptists" as all being "Asaniun," or Essenes.

The Nazirhood, a kind of voluntary priesthood, enjoining abstinence from wine, flesh, and other sensual enjoyments, had, in the troublous times of anti-Syrian agitation, and the general upheaving of society, found numerous adherents (*Tosifta Nazir*, c. 4; *Talm. Babli Berach*, 48, a. 1; *Macc.* ii. 49; *Jos. Antiq.* xviii. 1); and gradually there sprang up (contrary to the Bible, which restricts this asceticism to a certain period) a host of men calling themselves "Nazirs forever"—Nazire olam (*Nazir* 4, a.). Pharisees of a spiritual and contemplative bias, with no natural taste for the conflicts and activity of political or public life, or wearied, perhaps, with the vanity of human aims, took this vow of Nazirship for life, and constituted themselves into a sort of religious club. Levitical purity in its strictest and highest sense made them draw closer and closer the innumerable "fences" which the traditional law had erected round the biblical law. Any one, friend or foe, could, at any moment, by having touched something impure, disturb this purity for the time, and necessitate new and endless purifications. Thus it became necessary, or at least expedient, that those among them who could break all ties of friendship and family, should retire into a solitude not easily approach-

able by a stranger to their community. Food, again, could not be prepared save by those of the brethren who knew and strictly obeyed the hyper-traditional injunctions. Their dress, every implement of daily use, had to be made under similarly stringent laws of purity. A natural consequence of this their exalted notion of outward priesthood, was—the different phases of woman's life taken into consideration—their general celibacy. (The explanation given by Josephus—the fear of the corruption of both towns and women—is entirely gratuitous, and utterly in discordance with the Jewish notions of the time.) In this state of voluntary isolation, trading was out of the question; they tilled the ground, and lived on the fruits of the earth. Taking their meals, and these of the coarsest and plainest description, in common, they idealized the table into an altar, and, prayer having been said, they remained standing silently round it during the repast. That they had no individual property, follows of course, and their communistic motto, which the Mishna (Aboth) has preserved to us—"Mine is thine, and thine is mine"—explains itself. We need not enlarge further on their small eccentricities—on the white linen garment, the apron (*kenaphaim*), the scoop or shovel; they are, one and all, signs and symbols of Levitical purity, the scoop reminding us of a certain Mosaic ordinance during the wanderings in the desert, the apron becoming necessary from the frequent ablution of their hands. Every morning, they bathed, like the priests who ministered in the temple, in pure spring water. They abhorred blood as a source of impurity, and for this reason, probably, some of them abstained also from going up to the temple, where sacrifices were daily offered; others we find present at a festival in the temple (*Succah*, 51, 53). Their offerings were sent alive under the care of messengers. But these were but outward signs of purity, stepping-stones to inner piety, to communion with God, which was only to be acquired, according to their notion, by solitude and an ascetic life. The belief in the efficacy of the most rigid simplicity and willing self-sacrifice, they held in common with the Pharisees; their horror of oaths, their frequent prayers, their occupation with mystical doctrine, were their own. Untroubled by the noise of war or the strife of parties, leading a life divided between the bath, ablutions, contemplation, and prayer; despising the body and bodily wants; what more natural than that by degrees they should be led into a kind of mystical enthusiasm and fanaticism. They allegorized, they symbolized; and their efforts culminated in seeing the unseen. Absorbed in the attempt to fathom the mysteries of the nature of God, one of their principal occupations was the study of the name of God; of that unpronounceable name which only the high-priest dared utter once a year in the holy of holies during the most awful and solemn service on the day of Atonement. The knowledge of that name in four, in twelve, and in twenty-four letters, would give them the power of prophecy and of "receiving the Holy Ghost."

Angelology, derived from the Magi, formed a prominent feature of their creed. In course of time, they were looked upon by the vulgar as saints and workers of miracles. A wonderful book of cures (*Sepher Refuoth*), which Talmudic, Arabic, and Byzantine authorities alike ascribe to Solomon, was in their hands, and with this, "by the aid of certain roots and stones," by the imposition of hands, and certain whisperings—a practice strongly condemned by the Pharisees (*Synhedr.* 90, a.)—they cast out demons, and healed the sick. Philosophy they regarded in so far only as it treated of the existence of God. Jehovah is the original light; from him proceed a number of spirits (the Platonic ideas), and at their head stands the wisdom, or *logos*, into which, after death, the soul is again absorbed. Their code of ethics was threefold—the love of God, of virtue, and of man; their scale of perfectibility reaching its acme in the communion with the Holy Ghost (*Ruach Hakodesh*), (*Mishn. Sota*, 99). In fine, mixing up, in the strangest manner, the most exalted and the most puerile notions, they became the forerunners of the Christian Gnostics and of the Jewish cabalists, and, it may be, of many secret, still existing orders, who may have derived from this source their ceremonies and the gradations of initiation.

They seem never to have numbered more than 4,000, including even those Nazirs or E. who remained in their own families. Their colony appears to have been established chiefly near the Dead sea, and it is undoubtedly this colony which has served Josephus as a basis to his romantic E. republic. But, however distant from each other they might be, a constant intercommunication was kept up through a body of delegates, or angels (*Malachim*). As they had sprung from the Pharisees, so they again merged into them—part of them, we should rather say; the remaining part became Therapeutæ, or Christians. See THERAPEUTÆ and JEWISH SECTS. The Talmud gives a distinct account of their ceasing to exist as a separate community (*Bechorot*, 27), and so soon after their extinction did they fall into oblivion, that in the third century we find a Jewish sage asking who these *Hemerobaptists* had been (*Berachot*, 22, 1).

Much has been written and said of a certain literature which they possessed; on this we are unable to decide, deprived as we are of all trustworthy authority. One fragment only remains; it is quoted in the Talmud (*Jerusch. Berachoth*. End) in the following words: "It is written in the book of the *Chasidim*, If thou leavest it (the divine law) for one day, it will leave thee for two."

In addition to the Talmud and Midrash, we refer the reader to Josephus, *Antiq.* xv. 10, xviii. 1, *Jewish War*, ii. 7, 8; Philo, *Quod Omnis Prob. Lib.* § 12; Pliny, *Hist. Natur.* v. 17; Epiphanius, *Hæres.* xxix.; Hieronymus, Cyril, Chrysostom, etc. Beckermann, *Ueber die*

Ess. (1821); the histories of the Jews by Iost, Ewald, and Grätz; articles by Franckel; Sprenger's *Leben Mohammad's* (1861); and Lucius, *Der Essenismus* (1881).

ESSENTIAL NOTES in melodies are the notes that determine the nature of the accompanying harmony, so called to distinguish them from the *accidental* notes, which are of a purely ornamental character. Essential notes succeeding each other in a measure or part of a measure, and sometimes in more than one measure, belong to one chord.

ESSENTIAL OILS. See **OILS**.

ESSEQUIBO, the most westerly of the great rivers of British Guiana, rises in the Acarai mountains, 41 m. n. of the equator, and after a course of 620 m. enters the Atlantic near the Venezuelan frontier, forming an estuary 20 m. wide, in which lie numerous fertile islands. The E. receives numerous large tributaries, as the Cuyuni and Mazaruni; on the Potaro, another affluent, is the magnificent Great Kaietur fall, above 700 ft. in sheer descent, discovered in 1870. On the banks of the E. are forests of locust-tree, iron-wood, ebony, greenheart, and other fine timber trees, festooned with orchids, and laced together with lianas and other climbing plants. Beyond the forests are vast savannahs, formerly forests destroyed by fire, and now swamps of brushwood, reeds, and coarse grass. Its navigation is obstructed by cataracts and rapids. The region adjoining the river was the subject of the conflicting claims between the British and Venezuelan governments which led to the formation of the arbitration treaty of Feb. 2, 1897. See **ARBITRATION**. E. is also the name of one of three counties into which British Guiana is divided, the other two being Berbice and Demerara.

ESSES, **COLLAR OF**, a chain-like collar, composed of links in the shape of the letter S, found in various old insignia of England. It is said to have been worn by esquires especially. Some claim the SS to be the symbol of Saint Simplicius.

ESSEX, a co. in n.e. Massachusetts, on the New Hampshire border and the ocean, traversed by the Merrimack and Ipswich rivers, and the Boston and Maine, and several branch railroads; 503 sq. m.; pop. '90, 299,995. It has a rugged and uneven surface, and its business is mainly in manufactures of cotton, wool, leather, etc. There are quarries of granite and syenite. There are several cities and large towns in the co., and it has three co. seats, Salem, Newburyport, and Lawrence. It includes Cape Ann.

ESSEX, a co. in n.e. New Jersey, almost encircled by the Passaic river, and bordering on Newark bay; intersected by the Pennsylvania, the Delaware, Lackawanna, and Western, the Central of New Jersey, the Lehigh Valley, and the Erie railroads; 127 sq. m.; pop. '90, 256,098. The soil is fertile; but besides market gardening there is little of agriculture, the people being mostly engaged in manufactures. Co. seat, Newark.

ESSEX, a co. in n.e. New York, w. of lake Champlain, on the head waters of the Hudson, and intersected by Au Sable river, and the Champlain division of the Delaware and Hudson canal company's railroad; 1667 sq. m.; pop. '90, 33,052. In the w. part of this co. are the highest peaks of the Adirondacks, covering a large region entirely unsettled. The soil is fertile. There are beds of magnetic iron ore, and a number of extensive iron works. There are nearly 100 lakes, large and small, in the county. Co. seat, Elizabethtown.

ESSEX, the n.e. co. of Vermont, between the Connecticut and Passumpsic rivers, crossed by the Maine Central railroad; 730 sq. m.; pop. '90, 9511. It is a rough and cold region, not favorable to the growth of cereals. There are very large forests of sugar maple. Co. seat, Guildhall.

ESSEX, a co. in e. Virginia, bounded by the Rappahannock, which is navigable; 235 sq. m.; pop. '90, 10,047, includ. colored. The surface is uneven, and the soil for the most part sandy. Co. seat, Tappahannock.

ESSEX, a maritime county of the s.e. of England, having the North sea on the e., the Thames estuary dividing it from Kent on the s.; Middlesex and Hertford on the w.; and Cambridge and Suffolk on the north. Its greatest length from n.e. to s.w. is 63 m. and the greatest breadth from e. to w. is 54 m. It has 987,028 acres, most of its area being arable or in grass. The coast-line is 85 m. long. Some cliffs at the Naze are 35 ft. high. The center and n. of the county are beautifully diversified and richly wooded, the highest point being Langdon hill, 620 ft. above the sea, and in the s.w. is Epping Forest. Besides the Thames, the other chief rivers are the Stour, 50 m. long; Blackwater, 46 m.; Lea, Roding, Crouch, and Chelmer. The e. of the county is mostly on London clay, with limestone beds near Harwich. Pop. '91, 785,445.

ESSEX, a co. in the province of Ontario, Canada, between lakes Erie and St. Clair, traversed by the Grand Trunk and the Michigan Central railroads; 235 sq. m.; pop. '91, 55,545. Co. seat, Sandwich.

ESSEX JUNTO, a term used for the first time by a colonial governor of Mass. to designate a body of men from Essex co. which had arrayed itself against his corrupt policy. It was next employed by Gov. Hancock against certain conservative federalists of Essex co., who, 1781, nominated James Bowdoin as the representative of the traditional, as opposed to the popular, politics of the day. The most notable of this coterie were Theophilus Parsons, Stephen Higginson, Timothy Pickering, and George Cabot.

Pickering mentions in his diary that, although an Essex inhabitant, he never heard the term used until 1797, when John Adams spoke of such Mass. federalists as had been lukewarm in the campaign as members of the Essex Junto. It was a title invented by the opponents of conservative federalism; and although the men included in its ranks exercised a remarkable influence upon national politics, they never submitted to the charge of having formed a cabal or of starting any movement apart from the highest motives of statesmanship. Personally, they were of blameless character. See *Life and Letters of George Cabot*, by H. C. Lodge.

ESSEX, ROBERT DEVEREUX, EARL OF, son of Walter Devereux, first earl of E., was born at Netherwood in Herefordshire, 10th Nov. 1567; entered Trinity College, Cambridge, at the age of 10, where he remained for four years. Lord Burleigh, to whose guardianship he had been intrusted, introduced the handsome and gifted youth at court in 1584. Here, by his agreeable manners, his appearance, and talents, he established himself among troops of friends, and gained the special favor of Elizabeth. In 1585, he accompanied the earl of Leicester to Holland, where he distinguished himself at the battle of Zutphen, and on his return to England was made master of the horse and knight of the Garter. After the death of Leicester, E. continued to rise in the favor of Elizabeth, who loaded him with honors. In 1591, he commanded the forces sent to the assistance of Henry IV. of France against the Spaniards, but achieved no success. The next few years were spent in endeavoring to get the better of Burleigh—the wisest, the most prudent, and the most politic of all Elizabeth's advisers. In 1596, he was appointed joint-commander with lord Howard in the expedition against Spain, to which Burleigh was strongly opposed; and though E. displayed all his wonted courage, and contributed to the capture of Cadiz, which caused immense loss to the Spaniards, yet the expedition resulted in nothing, and E. had to defend himself against various accusations on his return. In 1597, he was made earl marshal of England, and, on the death of lord Burleigh, chancellor of Cambridge. In 1598 occurred the first fatal mistake in E.'s career. Presuming upon Elizabeth's admiration and feminine fondness for his person, he differed from her about some trifling matter, and angrily and rudely turned his back upon her in the presence of some of the council, and her majesty, whose language was hardly more delicate than her father's, gave him a vigorous box on the ears, telling him to "go and be hanged." A violent quarrel ensued, which, though apparently smoothed up, was never really so. E. was afterwards, in 1599, sent to Ireland—part of which at that time was in a state of rebellion—as lord-lieutenant of that country; but here his government was ill-advised and ineffectual, and after a few unimportant undertakings, he concluded a truce with the rebels, which was regarded at court as high treason. In order to confront his enemies, he hastened back to London, contrary to the queen's express commands, and forced his way into Elizabeth's bedchamber. Justly offended, the queen deprived him of his dignities, and commanded that he should be called to account for his behavior. E., advancing from one degree of foolhardiness to another, tried to excite an insurrection in London. He was imprisoned, tried, and found guilty. Elizabeth long delayed signing the warrant for his execution, in the hope that he would implore her pardon. He was beheaded on the 25th Feb., 1601, after defending himself with pride and dignity. E. was rash, bold, and presumptuous; but brave, generous, and affectionate, and the friend and patron of literary men.

ESSEX, ROBERT DEVEREUX, Earl of, 1591-1646. He was a companion of the prince of Wales. At the age of 15 he was married to Frances Howard, daughter of the earl of Suffolk, but nine years afterwards the marriage was annulled on account of the wife's intimacy with Rochester, earl of Somerset. A second marriage also ended unhappily. In 1620-23, he served in the wars of the palatinate, and in 1625 was vice-admiral of a fleet which made an unsuccessful effort to capture Cadiz. In 1639, he was lieutenant of the army sent against the Scotch covenanters; but no fighting was done. His summary dismissal made him an enemy of the king (Charles I.), and in 1642, he was commander of the parliamentary army. He won the battle of Edgehill, captured Reading, and relieved Gloucester; but in 1644, because of his unwillingness to fight the king in person, he lost nearly the whole of his army. In 1645, he resigned his commission, but was granted an annuity of £10,000 for his past services.

ESSEX, THOMAS CROMWELL, Earl of. See CROMWELL, THOMAS.

ESSIPOFF, ANNETTE, Russian pianist, b. in St. Petersburg in 1850. She received her musical education at the conservatorium in St. Petersburg, studying the pianoforte under Theodor Leschetitzky, to whom she was married in 1880. Mme. Essipoff has made numerous tours in Europe, and traveled in America, giving concerts with great success in 1876. She is one of the most brilliant pianists of the day.

ESSLINGEN, a manufacturing t. of Germany, in the kingdom of Württemberg, is situated near the right bank of the Neckar, in the center of a pleasing and fertile district, 7 m. e.s.e. of Stuttgart. It consists of the town proper, and five suburbs, and is surrounded by strong walls, and fortified by towers. The chief buildings are the *frauenkirche*—a splendid edifice in the purest Gothic style, built in 1440, surmounted by a spire 230 ft. high, and having five stained glass windows and three portals ornamented with excellent reliefs, the old and new town-houses, and the old castle. The church of St. Dionysius, a basilica in the transition style, stands in the market place, which also con-

tains St. Paul's church, in the early Gothic style. It has an important machine-making trade and a variety of manufactures, including a wine called Esslingen champagne. Pop. '95, 24,031.

ESSOUAN, or ESWAN. See ASSOUAN.

ESTABLISHED CHURCH, a church established and maintained by a state for the teaching of Christianity in a particular form within its boundaries. Subsequent to the reformation, many of the opinions which had given sanctity to the church of Rome still kept possession of men's minds; amongst these was the notion, that the civil government of each state was bound to maintain a particular form of Christianity. The same fallacious reasoning which in more recent times has led to the search for one absolutely best form of civil government was at work then with reference to the church. The Roman Catholic church was not the best form—of that the Protestant states had become convinced—but all forms were not therefore indifferent; and if one was better than another, and another better than that, there must be an absolutely best, which the state was bound to discover, and when discovered, to substitute for that which had been abolished. The idea that the good or bad qualities of forms of government, whether civil or ecclesiastical, so long as they did not violate the fundamental doctrines of Christianity or morality, were relative, and not absolute, and that whilst one might be the best for men in one stage of development or of one particular temperament, another might be the best for those who differed from them in these respects, did not belong to that age. Each Protestant state consequently established a church, conformity to the tenets of which it enforced, not only upon those who as ministers were henceforth to enjoy the property which in Roman Catholic times had been devoted to the spiritual interests of the community, but very often on its own civil servants and advisers. The benefit of the arrangement was, that, to a greater or less extent, the means which the community had set apart for its own spiritual improvement were protected from the spoliation of private individuals; and this benefit was secured more effectually the more completely the new church took the place of the old—in England, for example, better than in Scotland; but as each of the Protestant states had substituted one form of church-government for another, and as the same form had not been adopted by them all, the idea of there being one form which was absolutely preferable to the others, though not abolished, was rudely shaken. In England, queen Elizabeth had stated in her celebrated declaration, that she, as head of the church, “would not endure any varying or departing in the least degree” from the doctrines of the Episcopal church of England as set forth in the thirty-nine articles; and yet Presbyterianism was established in England in 1649. In Scotland, where Presbyterianism had at first taken root, Episcopalianism had more than once become the law of the land. The effect of such occurrences was to counteract the belief in any one form as the form for all Christendom, and to facilitate dissent and the formation of sects. The pastors of these sects were not at first recognized by the law as entitled to any of the privileges of Christian ministers. Whatever they might be to their own flock, to the state they were laymen, and their churches were mere secular lecture-rooms, or, at most, places of meeting for private devotion. See NONCONFORMISTS, DISSENTERS, CHURCH, etc. Gradually this view became modified, and the civil consequences attaching to sacred rites, when performed by a clergyman of the establishment, were extended to them when performed by dissenters. See MARRIAGE. But though many of the privileges, and all the liberties belonging to the established church, have now been extended to dissenting bodies, including Roman Catholics (see ROMAN CATHOLIC EMANCIPATION) and Jews (q.v.), the established churches of England and Scotland are supported by the state, and guarded from spoliation by the coronation oath (q.v.). The grant to the Roman Catholic college of Maynooth, and the *Regium Donum* (q.v.) to the Presbyterian ministers in Ireland, were capitalized by the act (1869) which disestablished the Irish church. There is no endowment to other religious denominations as in France; and the emoluments of the established church in England, though modified in their distribution by the labors of the ecclesiastical commissioners (q.v.), have not yet been appropriated to any other than religious uses in connection with that church.

The cause of established churches is very generally maintained on the ground of the alleged duty of the state to provide for the religious instruction of the whole body of the people, as most essential to their moral welfare, and so to the general prosperity of the community. It is further argued, in support of the same cause, that civil rulers, or the people as associated in a free state, are under a moral obligation of the highest kind, to acknowledge God, his law, and his ordinances. Concerning which, and other arguments, for and against established churches, as far as it belongs to the scheme of this work to notice them, the reader is referred to the article VOLUNTARIISM. It may here, however, be observed, that the arguments just mentioned do not necessarily infer, even when admitted to the utmost that the state is bound to support in any exclusive way a particular sect or denomination, unless on the further assumption that religious truth and worth belong to that denomination alone. Nor does the *endowment* of a church by the state necessarily follow from the fullest adoption of the principles thus contended for. And, on the other hand, it is a point which may very reasonably be disputed, how far the common arguments against state endowments are applicable to those endowments which were not originally bestowed by the state, but which the state has, from a

very early period, recognized as belonging to the church; a description which will be found to comprehend great part of the existing endowments of established churches.

ESTAFETTE, in Europe, an express for the conveyance of letters and small packages. The articles are consigned to the care of the postilions on duty along the route.

ESTAING, CHARLES HECTOR, Comte d', 1729-94; a French admiral, b. Auvergne. He first entered the army, and in 1757, as brig.gen., accompanied count de Lally to the East Indies. At the siege of Madras, 1759, he was made prisoner, but was released on parole. He at once resumed service in command of two ships of war, and being again taken captive in 1760, he was thrown into prison at Portsmouth for breaking his parole. He was soon released, and was appointed lieut.gen. in the navy in 1763, and in 1777 vice-admiral; and in 1778, commanded the fleet sent to aid the United States against Great Britain, bringing with him Gérard, the first French ambassador to the United States. He planned, with the American generals, a combined land and naval attack on Newport; and his demonstrations forced the British to burn or sink six frigates lying in the harbor; but lord Howe came, with an English fleet, to relieve Newport, and d'Estaing put to sea to engage him. A sudden storm separated the fleets, and d'Estaing put into Boston to repair his shattered ships. In Nov. he sailed to the West Indies, where he captured St. Vincent and Grenada, compelling the fleet which had come to relieve Grenada to retire to the harbor of St. Christopher. With 23 ships he co-operated, Oct. 9, 1779, in the unsuccessful attack on Savannah, and was himself wounded. The following year he returned to France. He commanded the combined fleet before Cadiz, when the treaty of peace was signed in 1783. Entering into French politics, he was elected to the assembly of notables in 1787, in 1789 he commanded the national guard, and in 1792 the national assembly chose him admiral. In 1793, he bore testimony in favor of Marie Antoinette. The following year he was himself brought to trial, condemned, and executed.

ESTAMINET (Fr.), a cheap coffee-house where smoking and liquor-drinking are allowed; a bar-room. "Frequenters of billiard-rooms and *estaminets*; patrons of foreign races and gaming-tables."—Thackeray. See CABARET.

ESTATE (Lat. *status*), in law, a term signifying, in its generic sense, the condition or circumstances in which an owner stands in regard to his property. In its more common and restricted sense, it is used to denote the *interest* which one has in lands, tenements or hereditaments. As thus employed, estates are divided, by the common law, with regard to their quantity into two general classes: (1) Estates of freehold and (2) Estates less than freehold. 1. A freehold estate is one for life or in fee. Life estates are either legal—*i.e.*, raised by operation of law, or conventional—*i.e.*, made by act, contract, or convention of the parties. The legal life estates are those held by courtesy (q.v.), dower (q.v.), or jointure (q.v.). Those that are conventional are made to last either for the life of the owner or for the life of some other designated person, or for an uncertain period which may continue during the life of the owner, such as an estate to a widow during her widowhood. Estates in fee, which are those of inheritance, are either fees-simple or fees-qualified. The fee-simple is the highest and most absolute estate, and is generally created or transferred, at common law, by the conveyance of real property to one and his heirs forever. The qualified fees are also created and transferred by the use of the word "heirs," but are restricted in some manner, so as not to give an absolute ownership. Thus, an estate to A and the heirs of *his body* gives him a fee-tail; an estate to A and his heirs, provided that intoxicating liquors shall never be sold upon the premises, gives him a fee upon condition, and an estate to A and his heirs, so long as they shall live in a designated place, gives him a fee upon limitation. 2. Estates less than freehold are either for years, or from year to year, or at will, or by sufferance. These are called chattels real, are personal property, and will be explained under LANDLORD AND TENANT (q.v.). With regard to the number and connection of their owners, estates are (1) Estates in severalty, or those in which each estate has only one owner; (2) Estates in joint-tenancy, or those held jointly by two or more persons in equal shares by purchase, and in such manner that, if one or more owners die, the entire ownership devolves upon the survivor or survivors; (3) Estates held by tenancy in common, or those of which two or more owners have undivided portions, but in such manner that, if one die, his right does not pass to his surviving co-tenants; (4) Estates in coparcenary, or those common law estates which descended upon two or more females upon the death of an intestate ancestor; and (5) Estates by entirety, or those held by husband and wife as such, in such manner that, on the death of either, the entire property belongs to the survivor and neither alone can convey any interest in the property so as to cut off such right of survivorship. Estates are also divided into legal and equitable, the latter including uses and trusts; and again into estates in possession and estates in expectancy, the latter including reversions, remainders and executory interests.

ESTATE, in a political sense, is a distinct class or order in society. The three estates under the feudal system were nobles, clergy, and commons. The feudal theory was that the basis of all power was property in land, and the clergy held their position in the feudal order by virtue of their landed proprietorship. The ambiguous position of the greater ecclesiastics as suzerain lords over territories, and at the same time spiritual ministers, led to the "war of investitures." Gregory VII. aimed to free the clergy from the duty of feudal homage to the secular prince. The result was the sepa-

ration of the two investitures, and a sharp distinction between spiritual and secular power. As the lay rulers grew stronger, the temporal authority of the clergy declined, until, at the present time, they form rather a corporation than a class. The history of the middle ages is a record of the rise of the "third estate." They were the representatives of the merchant class, the *bourgeoisie*. They first arose to prominence in the free cities of Italy and of the Hanseatic league. In Spain and England, especially, the absolute power of the crown was the product of the alliance of king and third estate as against the nobles. Before the "Union" (1707) the term "Estates of the Realm" was used in Scotland as equivalent to "Parliament." The States General of France, composed of the three estates, was seldom convened. At the outbreak of the Revolution the summoning of this body was resorted to when all other expedients failed. The old established custom was to vote by orders, but the third estate would thus have been outvoted in the new assembly. Its members determined to introduce the new principle of voting individually. In this they succeeded, and, with their success and the reorganization of the National Assembly, the French Revolution may be said to have begun. The term "fourth estate" is often applied to the press. Its first use in that sense is attributed by Carlyle to Edmund Burke, who pointed to the reporters' gallery in the house as containing a fourth estate more powerful than the other three.

ESTATE TAIL. See **ENTAIL**.

ESTÉ (ancient *Ateste*), a t. in the Italian province of Padua, situated on the southern slope of the Euganean hills, 15 m. s.s.w. of Padua. Pop. about 10,000.

ESTÉ, one of the oldest and most illustrious families of Italy, which, according to the historian Muratori, owed its origin to those petty princes who governed Tuscany in the times of the Carolingians, and who were in all probability of the race of the Longobards. The first whose figure is more than a mere shadow is Adalbert, who died about 917 A.D. The grandson or grand-nephew of Adalbert, named Oberto, was one of the Italian nobles who offered the crown of Italy to Otho of Saxony. He is afterward styled *Comes sacri palatii*, and appears to have been one of the greatest personages in the realm; he married a daughter of Otho's, and died about 972 A.D. In later times, the family of E. received from the emperors several districts and counties, to be held as fiefs of the empire. The family divided, at an early period, into two branches, the German and Italian. The former was founded by Welf or Guelfo IV., who received the investiture of the duchy of Bavaria from the emperor Henry IV. in 1070. The houses of Brunswick and Hanover, and consequently the sovereigns of Great Britain, also called Este-Guelfs, are descended from this person. In the 12th, 13th, and 14th centuries, the history of the E. family, as heads of the Guelf party, is interwoven with the destinies of the other ruling families and small republics of northern Italy. During this period, they first gained possession of Ferrara and the march of Ancona (1208 A.D.), and afterwards of Modena and Reggio (1288-89), and were widely celebrated as the patrons of art and literature. One of the most illustrious was Azzo VII., who encouraged Provençal troubadours to settle at his court at Ferrara, and also founded schools in that city. Alfonso I. (d. 1534) was equally distinguished as a soldier and a statesman, and was celebrated by all the poets of his time, particularly by Ariosto. His second wife was the notorious Lucrezia Borgia. His quarrel with the popes Julius II., Leo X., and Clement VII., was unfortunate, as an interdict was laid upon him for his adherence to the league of Cambray, and his papal fiefs declared to be forfeited. After the siege of Rome, in 1527, the duke was restored to his former possessions by Charles V. His successor, Ercole or Hercules II., who married Renate, daughter of Louis XII of France and Anne of Brittany, attached himself to Charles V. He and his brother, a dignitary of the Catholic church, were also liberal patrons of arts and sciences; the latter erected the magnificent villa d'Este at Tivoli. The next prince, Alfonso II. (d. 1597), would have been no ways inferior to the preceding but for his immoderate love of splendor, his inordinate ambition, and the cruelty he displayed toward the poet Tasso, whose eccentricities, however, it must be confessed, were enough to try the patience of any reasonable mortal. Alfonso IV., who flourished in the latter half of the 17th c., was very fond of the fine arts, and founded the Este gallery of paintings. *Rinaldo* (d. 1737), by his marriage with the daughter of the duke of Brunswick-Lunenburg, united the German and Italian houses, separated since 1070. The male line of the house of E. became extinct on the death of Ercole III. in 1803, his possessions having been previously seized by the French invaders, and annexed to the Cisalpine republic. His only daughter married the archduke Ferdinand, third son of Francis, emperor of Austria. Their eldest son, Francis IV., by the treaty of 1814-15, was restored to the territories which had belonged to his maternal ancestors, comprising the duchy of Modena; and, on his mother's death, obtained the duchies of Massa and Carrara. He was succeeded by his son, Francis V., 21st Jan., 1846. The connection which the family of E., like others of the small Italian principalities, had formed with Austria, gave it, of course, pro-Austrian sympathies, the result of which has been fatal to its popularity and dynastic existence. In 1860, the sentiment of Italian unity and independence, which for the previous 15 or 20 years had been steadily fostered by the policy of Sardinia, triumphed in a universal explosion of national feeling, which united the peninsula (with the exception of Rome and Venice) under the authority of Victor Emmanuel. Venice was added to the kingdom of Italy in 1866, and Rome became the capital in 1870.

ESTELIA, an ancient city of Spain, in the province of Navarre, is pleasantly situated on the left bank of the Ega, about 20 m. s.w. of Pamplona. It is a well-built, clean town, with several squares, and has, in the environs, a variety of agreeable promenades and pleasure grounds. It has two interesting churches, both old, and one of them, San Juan, a fine building with a very lofty tower. The manufactures are woolen and linen fabrics, brandy, and earthenware. A tolerable wine is made in the vicinity. E. has some trade in fruits, wool, hardware, and grain. Pop. about 6,000. Here Don Carlos was proclaimed king in Nov. 1833; and at E., again become a Carlist stronghold, battles were fought in 1874 and 1875.

ESTEPA, a t. of Spain, in the province of Seville, and 60 m. e.s.e. of the town of that name. It is, on the whole, well built; has several squares, and numerous religious edifices, among which are the churches of Santa Maria and San Sebastian. Pop. '87, 9059.

ESTEPO NA, a maritime t. of Spain, in the province of Malaga, and 25 m. n.n.e. of Gibraltar. It is well and regularly built. Pop. '87, 9771.

ESTERHAZY. See *ESZTERHAZY*.

ESTHER (the word signifies "the planet Venus") is the Persian name of Hadassah, daughter of Abihail, the son of Shimei, the son of Kish, a Benjamite. She is represented in Scripture as an orphan, and as having been brought up by her cousin Mordecai, an officer in the household of the Persian monarch Ahasuerus. Her history, as recorded in the book of E., is well-known and extremely interesting. When the misconduct of Vashti had cost her her "royal estate," all "the fair young virgins" of the kingdom were gathered together, that Ahasuerus might choose a successor. He selected Hadassah, who received the name of E. on account of her loveliness. The great event of her life was the saving of her Jewish countrymen from the horrors of that universal massacre planned by the malice of Haman, and consented to by the thoughtless cruelty of an oriental despot. The details of this event are too familiar to require narration. It is sufficient to say that E.'s success was signal; and the feast which she and her cousin Mordecai appointed in memory of their deliverance—viz., the feast of Purim (i.e., of Lots), is, in consequence, celebrated with great enthusiasm. E. is not mentioned in profane history, whence it has been inferred by some that she was not exactly the *wife* of Ahasuerus (Xerxes), but rather the favorite of his harem, to which she undoubtedly belonged; for, as we read (ii. 8), E. was consigned "to the custody of Hegai, keeper of the women." This hypothesis is rendered probable by the fact, that the Persian kings did not choose wives from their harem, but from the principal Persian families, or else from the daughters of foreign potentates.

ESTHER, BOOK OF, one of the very latest of the canonical works of the Old Testament, and commonly, but without a shadow of evidence, supposed to be written by Mordecai or Ezra. This is the view of Abenesra, Clement of Alexandria, Augustine, Gerhard, and others. The Talmud assigns the authorship to the members of the great synagogue, a semi-mythical body, who are made use of by Jewish rabbis and Christian divines as a sort of *Deus ex machina* to solve every difficulty. According to the opinions of the most learned and unprejudiced critics, the date of its composition must be placed after the downfall of the Persian monarchy. The language is much later than that of Ezra and Nehemiah, and the fact of occasional explanation of Persian customs fits the period of the Seleucidæ better than an earlier one. The Hebrew text is that which has been followed in the English version; but the Septuagint is full of late interpolations and additions by Alexandrian Jews. The book is held in the highest reverence by the Jews; so much so, that Maimonides declared that, in the days of the Messiah, every Jewish scripture would be forgotten except the book of Esther and the Pentateuch. The book is not written in a theocratic spirit, like the rest of Jewish literature. Nothing is directly attributed to God; in fact, his name is not once mentioned. Neither is there the remotest trace of religious feeling of any kind. Luther, in his usual off-hand hasty way, expressed his contempt for the book, in spite of the admiration which the Jews bestowed on it, censuring it for its "heathenish extravagance," and declaring that, in his judgment, it was "more worthy than all of being excluded from the canon." The absence of all recognition of God, perplexed some of the ancient Jewish commentators, who therefore invented the hypothesis, that the book was originally a part of the Persian chronicles, probably executed by Mordecai; and that, being intended for the heathen, the sacred name was wisely left out!

ESTHER, APOCRYPHAL BOOK OF. The Apocryphal Book of Esther consists of the canonical Book of Esther (q.v.) with some interpolations, and six chapters added at the end. It is worth noting that these chapters are found in the Septuagint version, but not in the Hebrew. Jerome placed all the additions as a sort of appendix to the Book of Esther; and they were not formally inserted among the Apocrypha until the time of Martin Luther, in whose version they were so classed. They are still accepted as canonical by the Roman Catholic Church and by the Greek Church. See *APOCRYPHA*.

ESTHONIA, called by the inhabitants themselves *Wiroma* (i.e., the border-land), a Russian government, and one of the Baltic provinces (q.v.) extends immediately s. of the gulf of Finland; has an area of 7818 sq.m., and a pop. (1892) of 406,819. It was

conquered (1182-1241) by the Danes, who sold it to the Teutonic knights in 1346. It came into the possession of the Swedes in 1561, but was taken from them by Peter the Great in 1710; and by the treaty of Nystadt was finally secured to Russia in 1721. The surface is in general flat, and the part which is under cultivation produces potatoes, rye, and barley; the rest is chiefly composed of sandy tracts and marshes, strewn in many places with large blocks of granite; there are also extensive forests of birch and pine. The government of E. is divided into four circles; its principal town is Reval or Revel (q.v.).

The population consists mainly of Esthonians, but in the towns the predominant element is German, and there are also Swedes and Russians. The Esthonians belong to the Finnish race, and are the original possessors of the soil. Their language is soft and musical and is divided into two leading dialects, that of Reval and that of Dorpat. They also possess a literature rich in splendid national songs. See Neus, *Esthonische Volkslieder* (Reval, 1830-51). They are industrious, kind-hearted, and in the main religious and attached to the Protestant doctrines. A great part of Livonia is peopled with Esthonians, who also are found in the provinces of Pskov and St. Petersburg, and have colonies in east Russia and Siberia.

ESTIENNE, or **ETIENNE**. See **STEPHENS**.

ESTILL, a co. in central Kentucky, divided into nearly equal parts by Kentucky river; 250 sq.m.; pop. '90, 10,836, inclu. colored. It has abundant water-power, and mines of iron and coal, with hilly but fertile soil. Co. seat, Irvine.

ESTOC (Italian), a small dagger worn at the girdle, called in Elizabethan times a tucke.

ESTOILE, or **STAR**, in heraldry, differs from the mullet (q.v.) by having six waved points; the mullet consisting of five plain points.

ESTOPPEL, an impediment or bar to a right of action, arising from a man's own act. It is called an E. or conclusion, because a man's own act or acceptance stoppeth or closeth up his mouth to allege or plead the truth.—*Co. Litt.* 352 a. Estoppels are of three kinds—1. By matter of record, where any judgment has been given in a court of record, the parties to the suit are estopped from afterwards alleging such matters as would be contradictory to the record. 2. By matter in writing. Thus, a party who has executed a deed will be precluded from afterwards denying, in any action brought upon that instrument, the fact of which it is evidence. 3. By matter in *pays*, as by livery, by entry, by acceptance of rent, etc.—by any of which acts a man is barred from pleading anything to the contrary. The principle of estoppel is that what a man has once solemnly alleged is to be presumed to be true, and therefore he should not be suffered to contradict. The doctrine of estoppel prevails in America as well as in England. In Scotland also, the same principle is recognized, under the name of personal exception (q.v.).

ESTOVER (Fr. *estoffer*, to furnish), an incident to the estate of a tenant for life or for years. It is the right which the tenant has to make use of the wood on the estate for certain definite purposes. Estovers, or *botes* (Saxon), are of three kinds—housebote, which is twofold—viz., *estoverium edificandi et ardendi*, a right to wood for fuel and repairs of the house, ploughbote, *estiverium arandi*, wood for plows and carts; and haybote, *estiverium claudendi*, wood for repairing hedges and fences.—*Co. Litt.* 41 b.

ESTRAYS, or **STRAYS**, domestic animals found wandering about without apparent home or known owners. In England the owner has a year and a day in which to claim such cattle, and the proprietor of the inclosure where they are found must make proclamation in a church and in market-towns. When these conditions are fulfilled they belong to the proprietor of the inclosure. The law of estrays varies in the different states of the American union. In some, after an estray has been advertised and kept for a certain time it is sold to pay the charges of advertising and keeping, any balance going to the town treasury. Cattle at large contrary to regulations, or breaking into growing crops and doing damage, can in most states be sent to a pound, and after a short time sold to pay damages and expenses.

ESTREAT (Lat. *extractum*), in English law, a true extract copy or note of some original writing or record, and specially of fines or amercements, as entered in the rolls of a court, to be levied by bailiffs or other officers. When, however, it is applied to a recognizance (q.v.), it signifies that the recognizance itself is estreated, or taken out from among the other records, and sent to the exchequer.—Blackstone, *Comm.* iv. 253. If the condition of a recognizance be broken, the recognizance is forfeited; and on its being estreated, the parties become debtors to the crown for the sums in which they are bound.—Archbold, *Crim. Practice*, 78. The court of exchequer has power over penalties and forfeitures incurred at assizes, and can discharge or compound them at its discretion; but that court has no power over recognizances forfeited before justices of the peace.

ESTRÉES, **GABRIELLE D'**, 1571-99; a beautiful French girl who, at the age of 16, became a favorite of Henry III. and about the same time of Cardinal De Guise and the dukes of Bellegarde and Longueville. In 1590 she met Henry IV. soon after his great

victory at Ivry. He became desperately enamored, but she did not immediately discard her old lover, the duke of Bellegarde. Henry gave her a husband in one M. de Liancourt, but soon afterwards divorced them and raised her to the rank of marchioness, and in 1595 to duchess of Beaufort. Henry lavished riches upon her, and when she died she was the owner of a dozen estates near Paris. The king desired to divorce his lawful wife and marry her, but Sully had sufficient influence to delay the matter until the death of Gabrielle. This event happened suddenly, and not a few persons suspected foul play. She had borne the king three children.

ESTRÉMADURA, next to Alemtejo the largest province of Portugal, has an area of 6876 sq. m., and, including the capital, Lisbon, contained, in 1890, 1,091,401 inhabitants. The greater part of the country is billy, but the hills do not attain any great elevation. To the w. of the estuary of the Tagus are the granite mountains of the Serra da Cintra, varying from 1500 to 1800 ft in height, and terminating in the Cabo de Roca. To the s. of the Tagus are barren moors, partly broken by morasses, and the limestone chain of Arrabida, rising to a height of 1000 ft. and terminating in the Cabo de Espichel.

ESTRÉMADURA, previous to the new distribution of the country, a province of Spain, situated between Portugal and New Castile, and watered by the Tagus and the Guadiana. It is bounded on the n. by Leon, on the s. by Andalusia, and, since 1833, has been divided into the two provinces of Badajoz and Cáceres. It has an area of 16,554 sq. m., and contained, in 1886, 799,659 inhabitants. Although a continuation of the high table-land of New Castile, E. is not, like it, a uniform plain, but is mountainous on the n. and s., and is well watered, the slopes of the hills being covered with wood, and the valleys with rich grass. Notwithstanding the fertility of the soil, the land has lain desolate and uncultivated since the expulsion of the Moors in the 13th century. This is chiefly to be attributed to the Mesta, or right of pasture, which causes the land to be regarded as the common property of the possessors of flocks. The breeding of goats, swine, horses, asses, and mules is much attended to. Silk and honey form no inconsiderable branches of trade. Corn is still imported. Copper, lead, silver and coal are found, but the mineral resources of the region are not developed. Commerce is confined almost entirely to a contraband trade with Portugal. The inhabitants are poor, and, from the want of roads, isolated from the rest of Spain, and consequently in a low state of civilization. They make excellent soldiers, however, and have produced a series of brave *conquistadores* and generals.

ESTREMOZ, a fortified town of Portugal in the province of Alemtejo, is 23 m. n.e. of Evora, and about the same distance e. of Elvas. It is built round the base of the hill on which its once formidable castle, erected in 1360, is placed. It now ranks as the fourth or fifth stronghold in Portugal. E. is famous for its manufactures of earthenware; its jars, which are made of a porous clay, and have the property of keeping water singularly cool, are of elegant shape, and are used all over the peninsula. The earthenware manufactures of E. seem to have continued unchanged since Roman times, as until the present day the forms into which the jars are cast are purely classical. In the neighborhood of E. is a marble quarry. Pop. about 7300.

ESTUARY. (Lat. *aestus*, the swell of the sea.) This word formerly denoted that part of the sea-coast which is covered during flood-tide but at ebb-tide is left a low bed of mud. As a modern geographical term, it denotes the enlargement of a river channel towards its mouth, in which the movement of the tides is prominent. Among the principal estuaries may be mentioned the entrance to the St. Lawrence river, that of the Rio de la Plata, the Thames in England, the Elbe in Germany, and the Gironde in France.

ESZEK, a royal free town of Slavonia, on the right bank of the Drave, 12 m. above its confluence with the Danube, is the administrative capital of the "Kingdom," and the most prosperous trading-town of Slavonia. Since the Drave began to be navigated downwards to E. by steamers, the town has driven a prosperous trade in corn, wool, pigs, iron, deals, wine, and flax. The fortress of Eszek, known in Roman times under the name of Mursia, is protected by a fort situated on the left bank of the Drave. In the fortress, the commander's dwelling and the town-house, and in the lower town the county buildings, are specially worthy of mention. During the Hungarian revolution, the town was at first held by count Casimir Batthyányi, but capitulated, after a siege of several weeks, to the Austrian general, Baron Treubersberg. Pop. '90, 19,778, a large part of whom are Roman Catholics, the rest being Greek Catholics, Protestants, and Jews.

ESZTERHÁZY, an ancient family of Hungary, afterwards raised to the rank of princes, and at present one of the richest and most powerful of the noble families of Hungary. In 1238 the family divided into the two branches of Zerhaz and Illeshazy. The male line of the latter became extinct upon the death of Count Stephen in 1838. The former received from the Emperor Sigismund, the Galanta estates in the county of Pressburg. The succeeding ruler, Francis IV., ennobled the three now extant lines, Csesznek, Zolyom or Altsohl and Fraknó or Forchtenstein, which were raised to the countship in the 17th century. The most important member of this house was NIKOLAUS (1582-1645), Palatine of Hungary, and belonging to the catholic and Legitimist party. The Fraknó branch further divided into the von Fraknó and Pápa branches, which in 1687 received the princely dignity from Leopold I. The counts of E. consist at present of

three lines, Forchtenstein, of the Pápa branch; Hallewyl, and Altschl. The most important members of the family are:—

ESZTERHÁZY, MORITZ, count of, 1807-1890, an Austrian diplomat, until 1856 Austrian ambassador to Rome, became a member in 1861 of the Schmerling cabinet, and a member of the Belcredi ministry, formed in 1865. He was prominent in the reaction party at the court of Vienna.

ESZTERHÁZY, PRINCE NIKOLAUS, count of Edelstetten, 1817-1894, hereditary prince of Forchtenstein, member of the Hungarian ministry, royal chamberlain and major in the army, married, in 1842, lady Sarah Frederica Caroline, daughter of George Child Villiers, earl of Jersey.

ESZTERHÁZY, NIKOLAUS IV., Prince Eszterházy of Galanta, 1765-1833. He traveled all over Europe in his youth, resided for a considerable time in England, France, and Italy, served in the Austrian army, and rose to be general, and later was prominent in diplomatic offices. He founded a splendid collection of pictures at Vienna, and also made a choice collection of drawings and engravings. When Napoleon, in 1809, entertained the notion of weakening Austria by the separation of Hungary, he made overtures to prince E. respecting the crown of Hungary, which, however, were declined. The great Haydn composed most of his works at the court of prince Nikolaus.

ESZTERHÁZY, PAUL ANTON, Prince Eszterházy of Galanta, 1786-1866. He was Austrian ambassador in Dresden in 1810, in Rome in 1814, and afterward minister in London until 1842. In the Hungarian uprising of 1848, he was minister of foreign affairs. After the suppression of the revolution he retired from public life. In 1856 he went as Austrian ambassador to the coronation of Alexander II. in Moscow.

ESZTERHÁZY, NIKOLAUS JOSEPH, Prince Eszterházy of Galanta, count of Forchtenstein 1714-1790, grandson of Paul IV., privy counselor and field-marshal, was ambassador to several courts, and distinguished himself in the war of the Austrian Succession, in 1745, at the head of 12,000 men in Silesia, and in 1757 at Kolin, and was made commander of the Order of Theresa, and in 1768 field-marshal, and is known also as a patron of the arts and sciences. Pleyel and Haydn were pupils in the musical conservatory founded by him in Eisenstadt.

ESZTERHÁZY, PAUL IV., Prince Eszterházy of Galanta, count of Fraknó and Beregh, 1635-1713. He was an Austrian field-marshal and was prominent in the Turkish war, particularly in the battle of St. Gotthardt, 1664. In 1681 he was elected Palatine of Hungary, and later overthrew the Tökölys party. He took part in the liberation of Vienna 1683, and aided in driving out the Turks from Ofen in 1686, and contributed to the strengthening of the Habsburg power in Hungary, for which he was raised to principedom, and later was given the right to coin money with his own likeness on it. He was also a prince in the Roman Empire.

ÉTAH, a district in British India, included in the division of Agra, s. of the Ganges; between 27° 20' and 28n., and 78° 30' and 79° 20' e.; 1741 sq. m.; pop. '91, 702,000. It is chiefly an elevated alluvial plain, with some fertile land. The productions are wheat, barley, cotton, sugar-cane, opium, indigo, etc. There are two harvests in the year. The manufacture of indigo is a leading industry. This region was the seat of a primitive Aryan civilization. Its capital is E. with a pop. '91, of 7800.

ÉTAMPES (anc. *Stampœ*), a t. of France, in the department of Seine-et-Oise, is situated 32 m. s.s.w. of Paris, on the Orleans railway. It consists mainly of one street, about 4 m. long. The chief buildings are the ecclesiastical edifices. E. possesses a public granary, and in and around E. there are numerous flour-mills, constantly employed in providing for the Paris market; there are various manufactures in the town; and considerable quantities of garden-stuff are sent from this neighborhood to the capital. Pop. '91, 8573.

ÉTAMPES, ANNE DE PISSELEU, Duchesse d', 1508-76; mistress of Francis I. of France, over whom she had very great influence. But she was exceedingly jealous of Diana of Poitiers, the mistress of the dauphin (afterwards Henry II.), and under this passion betrayed state and army secrets to Charles V. After the death of Francis she was banished from court.

ÉTANG DE BERRE, a salt lake of France, in the s. of the department of Bouches-du-Rhône, communicates with the sea by a narrow channel, called Tour-le-Bouc, and is 11 m. long by 9 broad at its widest part. This lake contains great quantities of eels and other fish. Salt-works are in operation on its banks.

ETAWAH, a t. of the Doab, stands near the left bank of the Jumna, about 70 m. below Agra, in lat. 26° 46' n., and long. 79° 4' east. Though it is, on the whole, a dreary and mean place, yet it presents some remains of ancient grandeur, more particularly many of those ghats or flights of stairs which facilitate the approach to the river for the purpose of ritual ablution. It contained (1891) 38,800 inhabitants; and its prosperity, such as it is, is owing chiefly to its position at the junction of the two roads which lead to Agra from Cawnpore and Calpee.

ETA' WAH, or **ITAWA**, the district of which the above town is capital, belongs to the lieutenant-governorship of the North-west Provinces. It lies entirely in the basin of the Jumna and almost exclusively within the Doab, stretching in n. lat. from 26° 21' to 27° 9', and in e. long. from 78° 46' to 79° 49', and containing 1691 sq. m., and (1891) 728,000 inhabi-

tants. The district was at one time famous for the murderous fanaticism of the Thugs, 67 corpses of their strangled victims having been found in the wells during a single year.

ETCHING. See **ENGRAVING**.

ETCHING UPON GLASS. See **GLASS**.

ETCHEMINS, formerly an Indian tribe in Maine, now represented by the Penobscots and the Passamaquoddies. They dwell between the Micmacs and the Abenakis tribes. There are about 1000 still left. Nearly all are Roman Catholics.

ETCHMIADZIN', **EDCHMIADZIN**, or **ITSMIADZIN**, a t. and monastery in the Russian government of Erivan, famous as the seat of the catholicus, or primate of the Armenian church. It is situated in the plain of the Aras or Araxes, about 2,985 ft. above the sea, 12 m. w. of Erivan, and 30 m. n. of Mt. Ararat. The monastery comprises an extensive complex of buildings, and is surrounded by brick walls 30 ft. high, which, with their loopholes and towers, present the appearance of a fortress. Its architectural character has been considerably impaired by additions and alterations in the modern Russian style. The cathedral is a small but fine cruciform building, with a Byzantine cupola at the intersection, a large tower at the western end, and a smaller tower above each wing of the transepts. It is here that the catholicus confers episcopal consecrations by the sacred hand of St. Gregory; and here every seven years he prepares with great solemnity the holy oil which is to be used throughout the churches of the Armenian communion. The library of the monastery is said at one time to have contained 15,000 volumes, and in spite of depredation and neglect, it still remains a rich storehouse of Armenian literature. Among the more remarkable manuscripts are a copy of the Gospels in a massive binding of carved ivory, dating from the 10th or 11th c., and three Bibles of the 13th c., one of which had belonged to Aytoun II., king of Armenia. To the e. of the monastery is a college and seminary of modern erection. At the distance of about half a mile stand the churches of St. Rhipsimé and St. Gaiana, two of the early martyrs of Armenian Christianity; the latter is of special interest as the burial-place of all those primates who are not deemed by the synod worthy of interment beside the cathedral. The town of Etchmiadzin, or as it should be called Vagharshapat, contains about 3,000 inhabitants, but has long ceased to be of any individual importance. According to Armenian historians, it dates from the 6th c. B.C., and takes its name from king Vagarsh, who, in the 2d c. A.D., chose it as his residence and surrounded it with walls. According to the legend, the great apostle of Armenia, St. Gregory the illuminator, having seen the Savior descend in a flood of light in the neighborhood of the palace, was ordered by an angel to erect a church on the spot. He observed the divine command in 309, and gave the building the commemorative name of "Edch-Miadzin," or "Descended the Only Begotten." In the Russo-Persian war of 1827, though the monastery was declared neutral territory by both belligerents, it was occupied by Russian troops.

ETEOCLES AND POLYNICES, sons of Œdipus and Jocasta, cursed by their father for shutting him up in prison. In order to prevent the fulfilment of his prediction that they would engage in fratricidal strife for the throne, they agreed to reign on alternate years. Eteocles, the elder, began, but when his year was up he refused to vacate. Then Polynices, resolved on revenge, fled to the court of Adrastus, king of Argos, whose daughter he married, and whom he induced to join his side in a war against Thebes. This expedition is known as "The Seven against Thebes," from the number of the chiefs who headed it, and is said to have occurred 27 years before the Trojan war. Eteocles and Polynices fought in single combat and both were killed. Of the seven leaders of the attacking force, Adrastus alone survived. Ten years after the close of the war, the fight was renewed by the descendants of the Argive chiefs who had been killed, this latter war being known as that of the Epigoni (descendants). The story forms the basis of *The Seven against Thebes* by Æschylus, and the names of the seven chiefs are mentioned by Sophocles, in his *Œdipus Coloneus*, and by Euripides in his *Suppliants* and *Phœnissæ*.

ETERNAL PUNISHMENT. See **ESCHATOLOGY**; **HELL**; **IMMORTALITY**.

ETESIAN WINDS (Gr. *έτος*, year), a name applied by the Greeks to particular winds that blew from the n. every year. Arising on the setting of the dog-star, they continued forty days. Arrian gives the same name to winds that blew from the s. across the Indian ocean.

ÉTEX, ANTOINE, b. Paris, 1808; a sculptor, pupil of Dupaty, Pradier, and Ingres. He traveled in Italy, Algiers, Germany, and England. He excelled in painting as well as sculpture, and published works on the two arts. He d. 1888.

ETH'ELBALD, d. 860; King of Wessex; son of Ethelwulf, king of the Anglo-Saxons. Ethelbald formed a conspiracy to seize his father's throne, but was dissuaded on being given the rule of Wessex only. He married his young stepmother, Judith, daughter of the king of France, but the displeasure of the church and of the people compelled them to separate, and she went into a French convent, from which she eloped with Baldwin of the Iron Arm, and from their union came Matilda, wife of William the Conqueror. The reign of Ethelbald was uneventful.

ETH'ELBERT, King of Kent, and fourth in direct descent from the great Hengist, was b. in the year 552, and succeeded to the throne in about the eighth year of his age. The representative of the first Saxon king who ruled in England, and envious on that account of the title of Bretwalda, then enjoyed by Cealwin of Wessex, E. rashly undertook an expedition against that king in 568, a venture which, had he known the

extent of country covered by the West Saxons, he would probably never have made. The rival kings met at Wibbandune, now Wimbledon, in Surrey, where a great battle took place, resulting in the defeat of Ethelbert. This is recorded as being the first battle that ever occurred between Anglo-Saxon sovereigns. Taught by disaster and danger, E. became more prudent. His subsequent schemes were more successful, and, about the year 590, he was acknowledged as Bretwalda of the Saxon octarchy, a dignity which he maintained to the close of his reign and life. In 570, E. married Bertha, a Frankish princess. The lady was a Christian, and it is said had stipulated, as a condition of her marriage, that she should be allowed, after her arrival in Kent, to practice her own religion. Her amiable piety had completely disarmed E. of all violence against the Christian religion long before the most important event of his life took place, viz., the formal introduction of Christianity into his kingdom. This was effected by means of the ministrations of St. Augustine, who was sent to Britain by pope Gregory, and who landed in Kent in 596. In the following year the king himself was converted, and Christianity established among the hitherto pagan Saxons. After his conversion and baptism, he founded the bishopric of Rochester, and, in concert with his nephew Sebert, king of Essex—who also had been converted—erected the church of St. Paul's in London. He died in 616.

E. is also distinguished as the author of the first written Saxon laws. These are the *Dooms*, as they are called by Bede, "which he established with the consent of his Witan in the days of St. Augustine." They are in the Saxon language, and are the earliest written laws that exist in any modern tongue.

ETHELBERT, d. 866; King of the Anglo-Saxons. He was a son of Ethelwulf and ruled all the kingdom except Wessex, succeeding to that portion also on the death of his brother Ethelbald in 860. It was during Ethelbert's reign that the Northmen, under the famous Ragnar Lodbrok, ravaged Kent, sacked the city of Winchester, and threatened London.

ETHELRED, or **ÆTHELRED**, I., d. 871; King of the Anglo-Saxons, succeeding his brother Ethelbert. He assumed the rule in 866, and his short reign was greatly disturbed by the forays of the Northmen under the sons of Ragnar Lodbrok. Ragnar had been captured and thrown into a den, where he was stung to death by serpents. His sons vowed vengeance. They seized the city of York and killed the princes who had captured their father; passed the winter in Nottingham, marched into East Anglia, destroyed several monasteries and nunneries, and killed Edmund, the king of East Anglia, of whom the church made a martyr. They were at last defeated by Ethelred, assisted by Alfred (afterwards the great), but two weeks afterwards they defeated Ethelred and Alfred at Basing. Ethelred died of a wound and Alfred became his successor.

ÆTHELRED, or **ÆTHELRED**, II., **THE UNREADY**, 968–1016; King of the Anglo-Saxons; son of Edgar and Elfrida. Careless of everything save his immediate comfort or whim, he and his kingdom were managed by unworthy favorites. In his time the Danes made many conquests in England, and forced Ethelred to purchase peace, to do which he laid upon his people the oppressive tax known as the "Danegeld," which was enforced at times for nearly 200 years. The Danes ravaged all the country around the river Humber, and in 994, aided by Olaf king of Norway, they laid siege to London, but the city was saved through the valor of its people. The Northmen then attacked the southern coasts, but they were hindered by the defection of Olaf, who embraced Christianity and became Ethelred's ally. In the last three years of the 10th c., the Danes ravaged Kent, Sussex, and Wessex. In 1000 the Anglo-Saxon king, disregarding the enemy at home, invaded Normandy, where he was disastrously defeated; but he made a treaty, and married Emma, the daughter of the duke of Normandy. In the spring, he concluded a treaty with the Danes; but, on pretense that they were plotting treachery, the next winter he ordered the murder of all the Danes in England. Among the victims was Gunold, sister of Swend, king of Denmark. Swend was swift in his revenge, and for four years his army ravaged almost at their pleasure in England. In 1007, Ethelred again bought peace for a large sum of money. In 1009, Ethelred collected the "largest fleet that had been seen in the reign of any king," with the intention of driving the Danes from the sea; but the fleet was almost wholly destroyed by a storm; the Danes renewed their ravages, and the English suffered many defeats, until another peace was purchased for money in 1012. The next year Swend, with the largest fleet he had ever collected, sailed up the Humber and marched towards London; but he met such strong resistance that he gave up the plan of attacking the city, and turned off to Bath, where he was proclaimed king of England by the people, who were weary of Ethelred's incompetency and exactions. London soon acknowledged Swend, and the deposed Anglo-Saxon king fled to Normandy. Swend died in the spring of 1014, and Ethelred was re-called on promising to rule better in the future. In the same year he defeated Cnut (Canute), son of Swend, but in 1015 Cnut ravaged a large territory, and was about to attack London when Ethelred died.

ÆTHELREDA, **SAINT**, a daughter of the king of the East Angles, in the 7th c. canonized for her saintly virtues, and whose festival in the calendar is Oct. 17. Her name was popularly abbreviated or corrupted into St. Audrey. At a fair in the isle of

Ely, called after her St. Audrey's fair, it was customary to sell a common kind of lace, which came to be known as St. Audrey's lace. *Tawdry*, as applied to any inferior kind of frippery, is believed to be a corrupt use of the term St. Audrey.

ÆTHELWULF, or **ÆTHELWULF**, d. 858; King of the Anglo-Saxons, son of Egbert. Ethelwulf's reign was mainly occupied in wars against the invading Danes. In 855, E. made a journey to Rome, taking his youngest son (afterwards Alfred the Great) to have him consecrated as his successor. In France he married Judith, a daughter of the king of the Franks (afterwards married to Ethelbald, her step-son). In consequence of the preferment of Alfred for succession, the eldest son, Ethelbald, planned a revolt, but was pacified on his father's giving him the kingdom of Wessex. See **ÆTHELBALD**.

ETHER (otherwise called **ETHYLIC ETHER**, **VINIC ETHER**, and **SULPHURIC ETHER**) is prepared from alcohol by the action of sulphuric acid at an elevated temperature. On the small scale the apparatus which may be employed for the purpose is the retort and receiver, into which a mixture of equal weights of spirits of wine, or rectified spirit, and oil of vitriol, or, by volume, 2 of alcohol and 1 of sulphuric acid, are placed, and heat being cautiously applied, a liquid distils over, which consists of ether and water. In a short time the contents of the retort begin to blacken, and the operation must be stopped or the distillate will become contaminated with sulphurous acid. On the large scale a modification of the process is carried on, which renders it theoretically a "continuous process," though, practically, there is a limit to the amount of ether distilled over.

The conversion of alcohol, $2C_2H_5OH$, into ether $(C_2H_5)_2O$ and water, H_2O , by oil of vitriol, H_2SO_4 , was at one time considered to be due simply to the strong affinity of the oil of vitriol for water, which enabled it to take possession of the one atom of water, the elements of which form the only difference in the ultimate composition of alcohol and ether. This simple mode of explaining the process of etherification, however, does not acknowledge that the atom of water is not retained by the oil of vitriol, but is given off side by side with the E. in mechanical solution therewith. The theory of the process now generally accepted is too complex for introduction here.

E. is a colorless, transparent, volatile liquid of great mobility and high refractive power, and possessing a fragrant odor, and a fiery, passing to a cooling, taste. When pure, it has the specific gravity 720 (water = 1000) at $60^\circ F.$, though the commercial specimens are never free from water and alcohol, and have the density 740. It boils at $94.8^\circ F.$ ($34.9^\circ C.$) (the commercial at 96°), and yields a very dense vapor, the specific gravity of which is 2586, as compared with air 1000. When reduced to a temperature of $-24^\circ F.$ ($-31^\circ C.$), E. freezes. It volatilizes spontaneously when placed in an unconfined position, as in the palm of the hand, and vaporizes so quickly as to produce intense cold. Indeed, when water is covered with E., and the latter assisted in its evaporation by being blown upon, it escapes so readily as to reduce the temperature of the water to $32^\circ F.$, when it freezes. It is very inflammable, burning with a yellow-white flame; and mixed with air or oxygen, it gives rise to a dangerous explosive mixture, and hence great care requires to be taken in its distillation to keep all lights and fires out of the room where the vapors are condensing. When E. is added to its own bulk of water, briskly agitated, and allowed to settle, the two liquids appear to separate again; but it is found that the E. has taken up one-eighth of its volume of the water, whilst the latter has dissolved the same quantity of ether. It is readily miscible with alcohol in all proportions. E. is one of the best solvents for the oils and fats, and hence is employed in analysis for the solution and separation of the oils from other organic matters, as in the analysis of oil-cakes, etc. It is also a good solvent of iodine, sulphur, phosphorus, and of strychnine, and other alkaloids, as well as of corrosive sublimate, and other salts.

E. is useful in the preparation of freezing mixtures, and the mixture of E. and solid carbonic acid gives rise to the lowest temperature which has as yet been attained. When inhaled by man and the lower animals, E. first produces stimulating and intoxicating effects, but afterwards it gives rise to drowsiness, accompanied by complete insensibility, which entitles E. to be regarded as an important anæsthetic agent; and, indeed, for some time it was the only agent used for producing anæsthesia (q. v.) in operations, but has been partly superseded by the employment of chloroform.

The radical of ether, C_2H_5 , substitutes the hydrogen in many acids, forming compound ethers, possessing great fragrant; the more important of which are given in the following table:

| | | |
|-----------------------|--------------------------------|----------------------|
| Acetic Ether..... | $C_2H_5 \cdot C_2H_3O_2$ | |
| Butyric Ether..... | $C_2H_5 \cdot C_4H_7O_2$ | Pine-apple Oil. |
| Caproic Ether..... | $C_2H_5 \cdot C_6H_{11}O_2$ | } Essence of Melons. |
| Rutic Ether..... | $C_2H_5 \cdot C_{10}H_{19}O_2$ | |
| Pelargonic Ether..... | $C_2H_5 \cdot C_9H_{17}O_2$ | Essence of Quinces. |
| Enanthic Ether..... | $C_2H_5 \cdot C_7H_{13}O_2$ | Wine Oil. |

There are other ethers, in which the radical of ether is not one of the members, as

| | | |
|-----------------------------|-----------------------------|-----------------------|
| Amyl Acetic Ether..... | $C_5H_{11} \cdot C_2H_3O_2$ | Jargonelle Pear Oil. |
| Amyl Valerianic Ether..... | $C_5H_{11} \cdot C_5H_9O_2$ | Apple Oil. |
| Methyl Salicylic Ether..... | $CH_3 \cdot C_7H_5O_3$ | Oil of Winter Greens. |

ETHER, sometimes **ÆTHER**, the name given to the medium which is assumed in astronomy and physics as filling all space. It was shown by Newton, that if light consisted of material particles projected from luminous bodies, these must move *faster* in solids and liquids than in air, in order that the laws of refraction might be satisfied in their motions. Huyghens, on the other hand, showed, that to account for the same laws on the supposition that light consisted in the undulatory motions of an elastic medium, it must move more *slowly* in solids and fluids than in gases. Fizeau and Foucault have lately, by different methods, measured these velocities relatively, and have found Huyghens's prediction to be correct. Light, then, consists in the vibratory motion of a medium, which must, of course, fill all space. This is called ether. As yet, we have no idea as to its ultimate nature; some of our greatest philosophers, even, have supposed that it may be of the class of ordinary gases, and that our atmosphere, for instance, is not finite in extent, but pervades, with greatly reduced density, all interplanetary and interstellar space. Many objections, however, may easily be raised against this supposition. Meanwhile, we may remark, that the mathematical theory of light, on the hypothesis of undulations, requires that the vibrating medium should possess properties more nearly allied to those of an elastic *solid* than those of a liquid or a gas. The E. being *required* for the explanation of the existence and the propagation of light, it becomes a matter of importance to inquire how many more of the physical forces may be referred to the same cause or medium. Radiant heat most certainly may, and, in all probability, gravitation, molecular actions, magnetic, electric, and electro-dynamic attractions and repulsions, are also to be thus explained. As to sensible and latent heat, electricity and magnetism themselves, the necessity is not so clear; but even these have been of late *almost* satisfactorily explained by the hypothesis of the all-pervading ether. See **FORCE**. In the article just referred to, a good deal more will be found with reference to this subject, and especially with reference to the impossibility of the E.'s consisting of air or other gases, which are made up of distinct and separated particles.

Many of the ancient philosophers had a shadowy idea, or theory it may be called, in regard to the medium which we term cosmic, or luminiferous, ether. The ancient Greeks personified it, *Æther* being, according to Hesiod, the son of Erebus and Night, and the brother of Day. They also regarded this personification as the representation of the great force of the universe, as well as original matter, which, in a mysterious union with this force, evolved the worlds. The Orphic hymns speak of *Æther* as the soul of the world, the animator of all things, the great principle of life, the divine essence. The children of *Æther* and Day were the objects of the visible creation, the heavens with all their stars, the land, the sea. *Æther* was the lightest and the most active form of matter, and Day had the power of converting it into heavier and visible matter. It seems as though the human mind has the power, given it by the creator, of foretelling great truths afterwards to be demonstrated. Plato spoke of *æther* as being a form of matter far purer and lighter than air; so light that its weight cannot be ascertained because diffused through infinite space. It would at first appear surprising that the substance which Huyghens found it necessary to assume to demonstrate the laws of reflection and refraction, and particularly of double refraction, should not have been regarded by the greater portion of the scientific world as a reality, as a substance necessary for the performance of many physical phenomena. But Newton's emission theory of light, or, perhaps it may more correctly be said, his elaboration of the emission theory of Descartes, held the belief of the world for nearly a century and a half, and this theory did not require the supposition of such a medium, although both Newton and Descartes conceived of its existence. Huyghens's undulatory theory was so thoroughly founded upon the doctrine of an ether that its opponents were perhaps, in their opposition to his theory, insensibly led to ignore the existence of this medium; for the propagation of light by the emission of particles of matter needed no medium for them to pass through; they could pass through vacuous space, although there were some phenomena which seemed to suggest that the assumption of such a medium would aid in their explanation. But Huyghens's theory required the existence of the medium, although, strange as it may seem, the great mathematician Euler, an advocate of the doctrine of undulations, rejected the doctrine of an ethereal medium. Prof. Grove, a modern British scientist, in his essay on the *Correlation of Physical Forces*, offers the following arguments, here briefly stated, against the doctrine of a cosmic ether. The tendency that the particles of bodies have to fly off into space is so great that it has been impossible hitherto to cause an inclosed space to be void of ponderable matter. Gaseous matter has so strong a tendency to fly off into space that no part of the universe could, after a time, be free from its particles. Again, it must be assumed that light is lost in the interstellar spaces, because, if it were not so, there could be no night, all of the stars being suns. Now, an argument which chimes in with the doctrine of the correlation of physical forces, is that the light from these innumerable suns is transmuted into another force, and this requires the existence of matter in the spaces, such matter as would be furnished by the expansion into space of the aerial matter which envelops the different worlds. The strongest arguments in favor of the belief in a cosmic ether are that it allows of a perfect explanation of all the phenomena of radiation, refraction, diffraction and polarization of light, and that such explanation cannot be made without assuming the existence of such a medium. See **HEAT**; **LIGHT**.

ETHEREGE, or **ETHERIDGE**, Sir **GEORGE**, 1636-89; b. London; educated at Cambridge, and traveled in the continent, where he saw some of Molière's dramas. After the restoration of Charles II. he began to write for the stage, producing first *The Comical Revenge, or Love in a Tub*, which was highly successful. He was at once admitted to the circle of wits and poets of the time, and led a careless and somewhat loose life. By a questionable alliance with Mrs. Barry, the actress, he had one daughter, who died young. Among Etheridge's plays were *She Would if She Could*, and *The Man of Mode, or Sir Fopling Flutter*, in which the chief character was a portrait of Beau Hewitt, the Brummel of the period, while he represented in other parts Sir Charles Sedley, and also himself. But he fell to gambling and lost his fortune. Then he married a rich widow, and again had money. In 1686, he was appointed resident minister at Ratisbon, where it is said that while conducting a party of friends to the stairs after a banquet he fell over the banisters and broke his neck.

ETHICS, a word of Greek origin, meaning nearly the same thing as the more familiar term morals. The science, treating of the nature and grounds of moral obligation, and expounding our various duties, is called sometimes by the one term, and sometimes by the other. This is a subject wherein opinions so different from each other have been, and are still held, that a writer's task must lie first in explaining what are the chief points in dispute, and next in giving an account of the positions taken up by the opposing schools.

There are two distinct questions connected with the theory of morals. The first is the properly ethical question, and is, what is *the criterion of a moral act*? otherwise expressed as the *moral standard*—the circumstance determining an action to be *right*, and not *wrong*, nor simply indifferent as regards right and wrong. What determines us to single out some conduct as the subject of *moral approbation*, and other conduct as the subject of *moral disapprobation*? We consider murder, theft, breach of promises or contracts, resistance to authority, cruelty, ingratitude, slander, holding of slaves, polygamy, to be wrong, or immoral; and the science of E. is called upon to assign the reason, or reasons, why these various actions are so accounted.

The other question is properly psychological; in other words, relates to the constitution of the human mind. It is, by what *faculty of our nature* do we recognize this difference in actions? Is it by one of our ordinary intellectual faculties, such as reason? or by some of our emotional susceptibilities, as love and hatred? or by a mixed faculty like prudence? or by something peculiar and distinct, relating to this one object and no other, as the eye is formed for recognizing color, and the ear for sound? This question has been often improperly mixed up with the other, although there are certain theories wherein the answer to the first depends on the answer to the second.

As regards the standard of morals, it should be premised that punishment for neglect is what shows an action to be obligatory. We may dislike a man's conduct; but if we do not consider it deserving of punishment, it is not immoral in our eyes. People's imprudences, whereby they hurt themselves alone, are disapproved of; but there is seldom any disposition to step in by way of penalty in order to prevent such conduct; the disapprobation, therefore, is not of the moral kind. The punishment inflicted by society is partly legal, or through the civil government, and partly by public opinion, which, by attaching a stigma to certain conduct, is able to inspire no less dread than the civil authority. The punishment, by society acting in this way, is sometimes called the popular sanction, to distinguish it from the legal sanction. *Dishonor* is another name for the same thing. Many kinds of conduct tolerated by law, are still punished by the loss of public esteem and the infliction of disgrace. Cowardice, eccentricity, heterodoxy beyond certain limits, expose the individual to public censure. Many kinds of inhumanity, as maltreating dependents, have no other check than expressed disapprobation.

There have been various theories to account for the singling out of some actions to be authoritatively forbidden by law and society—that is, forbidden by the sanction of punishment. Some have said that the will of the Deity, or divine revelation, has indicated what we are not to do, and that there is nothing left to us but to conform to what is thus prescribed; others, as Cudworth, maintain, on the contrary, that what the Deity commands must be such as our own conscience approves, otherwise we could not give him the character of being independently good and just. It has been said that right reason shows us the difference between right and wrong; this was Cudworth's own view. Samuel Clarke conceived that there was an eternal and intrinsic *fitness* in the things considered as right, and an unfitness in the wrong, "with a regard to which the will of God always chooses, and which ought likewise to determine the wills of all subordinate rational beings." Both these writers aimed at replying to Hobbes, who had maintained that the civil magistrate is supreme in morality as well as in politics; meaning, however, in all probability, that the magistrate himself ought to frame his dictates in one, as in the other, with a view to the public good, which would be a utilitarian view. The phrase "the moral sense," which now represents perhaps the most prevalent moral theory, occurs first in Lord Shaftesbury's *Inquiry Concerning Virtue*, from whom it was adopted by Hutcheson, and has since passed into general currency. Sometimes it has been maintained that a regard to self-interest is the only ultimate rule of right, which

has a very different meaning, according as we look at self exclusive, or inclusive, of other men's wellbeing. The most enlarged benevolence, in one view, is but an aspect of self. Adam Smith, in his *Theory of Moral Sentiments*, laid down as the criterion of right, the "sympathetic feelings of the impartial and well-informed spectator." But although this theory acknowledges our bias in the capacity of agents, it presumes us to be infallible when acting as judges or critics, a position by no means self-evident. The spectator has his own failings as well as the actor, unless specially qualified by nature and education to play the part of a moral judge. But to pass on. Jeremy Bentham is known as the most distinguished propounder of the principle of utility as the basis of morals, a principle explained by him as in contrast, first to asceticism, and next to "sympathy and antipathy," by which he meant to describe all those systems, such as the moral sense theory, that are grounded in internal feeling, instead of a regard to outward consequences. In opposing utility to asceticism, he intended to imply that there was no merit attaching to self-denial as such, and that the infliction of pain, or the surrender of pleasure, could only be justified by being the means of procuring a greater amount of happiness than was lost. Paley also repudiated the doctrine of a moral sense, and held that virtue is "the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness." The utilitarian theory of Bentham, with various modifications, has been defended and expounded by James Mill, in his *Analysis of the Human Mind*, and in his anonymous *Fragment on Mackintosh*; by John Austin, in his *Province of Jurisprudence Determined*; and by Mr. John Stuart Mill in his *Dissertations and Discussions*, and in *Fraser's Magazine* (Oct. to Dec., 1861).

The great controversy may be said to lie between the adherents of the moral sense in some form or other, and those that deny both the existence of a separate faculty in the mind for perceiving moral distinctions, and the validity of the determinations of the individual conscience; maintaining that morality ought to be founded on a regard to the well-being of mankind, and that exclusively; and that rules of morality grounded on any other motives are indefensible. In short, the question is, Is morality an intuition of the mind, or is it, like the government of the state, a positive institution, on which different societies may differ, and which may be set up or abrogated at the pleasure of the society?

The theory of intuitive morality was vigorously assailed by Locke in his *Essay on the Understanding* (book i. chap. 3); and we may venture to say that his objections to what he called "innate practical principles" have never been answered. These objections have been given in a condensed form by Paley (*Moral Philosophy*, book i.). Locke urged that, in point of fact, there are no principles universally received among men; that moral rules require a reason to be given for them, which ought not to be necessary, if they are innate; that virtue is generally approved of, not because innate, but because profitable; that innumerable enormities have been practiced in various countries without even causing remorse; that the moral rules of some nations are flatly contradicted by others; that no one has ever been able to tell what the innate rules are; that we do not find children possessed of any moral rules, etc. It has been attempted to reply to the objection, founded on the great variety and opposition of moral rules in different places and times, by saying that although the substance of the moral codes differ—one part of the world being monogamous and chaste, while other nations allow promiscuous intercourse of the sexes—all agree in enjoining some moral rules; nowhere is there an absence of social and moral obligations. But this is to depart from the original question, which was to assign the standard of morals, the criterion for determining which of two opposite courses—monogamy or polygamy—is the correct or moral course. The intuitive moralists say that human nature is endowed with an instinct which at once approves the right and disapproves of the wrong, and that we need go no further than our own conscience to settle the point. Now, when the existence of contradictory consciences is pointed out, it is not to the purpose to say that these are still consciences, and indicate something as obligatory; this all admit: what we desire is to determine which we are to follow.

Dr. Whewell, in his *Elements of Morality*, has proposed a way out of this serious difficulty by setting up a supreme or standard conscience, by which the individual conscience may be squared and corrected; but he has not told us who are the men whose conscience is the standard; it being obvious that the human race, as a whole, do not recognize any such, although each separate community might consent to take some of its most estimable citizens, or the interpreters of its religious code, as models to conform to.

The following is one view of the nature and origin of our moral principles which would seem free from the grave objections above alluded to. If we set aside for the present the question as to the *proper* standard of morals, the criterion that we should consider the right criterion, if we had to enact a code of morals for the first time, and if we look at the moral principles that have prevailed in different nations and times, we shall find that they have been dictated from two distinct kinds of motives. The one is utility, in the sense of the common safety of men living in society. The prohibitions against manslaying, theft, breach of bargain, rebellion, are necessary, wherever men have formed themselves into communities; and it is the agreement in such matters as these—although subject still to very great varieties—that makes up the amount of

uniformity actually observed in the moral codes of nations. If the society did not agree to protect life and property, by punishing the murderer and the thief, nothing would be gained by coming under the sway of government, and human beings would not be got to associate themselves in tribes or nations. The common end gives a common character to the means, without supposing a special instinct to suggest that stealing is wrong. But, in the second place, there have been, in the moral codes of all countries, prohibitions not connected with any public utility, but prompted by strong sentimental likings or aversions, which have acquired the force of law, and are made the foundation of compulsory enactments. Of this kind is the antipathy of the Jew and the Mohammedan to the pig, the Hindoo repugnance to animal food generally, and the usages of a merely ceremonial kind prevailing among many nations, which are as stringently enforced by law and public opinion as the sacredness of life and property. For a woman, among the Mussulmans, to expose her face in public, is as great an offense as going naked would be with us; while, among savage tribes, in warm climates, where clothing is little required, it is no shame to expose the whole person. For these practices, no reason can be given; the public sentiment has determined some things to be right and others wrong, without reference to any public or private utility; and it is in these enactments, founded on liking or disliking, that nations have differed most widely, the difference often amounting to contrariety. The ancient Greeks held it as a sacred obligation to drink wine in honor of Dionysus (Bacchus); the Nazarenes among the Jews and the Mohammedans entertained an opposite view. A legislator for the North American Indians might prohibit alcoholic liquors on the ground of public utility, the natives not being able to control themselves under stimulants; but the prohibition of wine in those other instances is probably a species of asceticism, or an aversion to human pleasures as such, which belongs to the domain of sentiment, and not to the consideration of utility.

Looking at the many capricious injunctions that owe their origin to fancies such as these, it may be doubted whether the human race can ever gain anything by departing from the principle of utility as the sole criterion of good morality; and there is an increasing tendency to recognize the supremacy of this principle both in morals and in legislation. Justice, truth, purity, although sometimes viewed sentimentally, or as being ends themselves, are in men's practice looked upon more and more as of the nature of *means*, the promotion of human happiness being the end.

A great number of the existing moral rules can be traced to a distinct historical origin, proving still more decisively that they are not the suggestions of a universal instinct of the human mind. The Mohammedan code of morals came from Mohammed; Confucius was the moral legislator of one large section of the Chinese. The making of the marriage tie irrevocable in Christendom was an exercise of papal authority in the 13th c., and has since been repealed in some Protestant countries, although retained in Catholic states. See *DIVORCE, MARRIAGE*. The sentiment which forbids the holding of human beings as slaves is chiefly the growth of the last two or three centuries.

Although the doctrine of intuitive morality is, in this view, denied, it is still admitted that there is such a power in the mind as conscience, which warns us when we are doing wrong, and is to a certain extent a force to make us do right. But it cannot be shown that we are born with any such principle, combining both enlightenment and motive power. Conscience is a *growth*. There are in our constitution certain primitive impulses that so far coincide with what is our duty, and therefore contribute to the formation of the conscience; these are principally self-preservation, or a regard to ourselves, and sympathy, or a regard to others. There are many duties that we are prompted to for our own interest, such as telling the truth, in order that people may confide in us; obeying the laws, to avoid punishment, etc. But we cannot perform all our social duties if we look merely to ourselves. We must, in addition to prudence, have a source of *disinterested* action, inducing us both to avoid injuring our fellow-beings in the promotion of our own selfishness, and occasionally to sacrifice ourselves for the sake of others. Such a principle exists in our mental nature, although not of equal strength in all minds. Being provided with these two primitive springs of action, we are susceptible of being educated to the sense of moral obligation. The child is first taught obedience by penalties, and is made to associate pain with forbidden actions. This is the germ of conscience. Habits of avoiding what is prohibited under penalties are gradually formed, and the sense of authority and law is thereby acquired.

When the powers of observation and reason come to maturity, the individual sees why the restrictions of duty have been imposed, and is then ready of his own accord, and apart from the fear of punishment, to behave rightly. The conscience, grounded on fear, then becomes the conscience grounded on spontaneous approval.

Conscience thus follows, and does not precede, the experience of human authority. Authority, sanctioned by punishment, is the type and the starting-point, even when the conscience takes an independent flight, and adopts rules for itself different from those that entered into its education. The great mass of human beings have nothing more than the slavish conscience, or the habits imparted by the exercise of the parental and public authority, which shows what is the most natural foundation of moral sentiment. The persons that judge of right for themselves, instead of implicitly receiving the maxims peculiar to the society where they grow up, are so few as to be

the exception everywhere; their conscience does not prove what is the usual endowment of human nature in this respect.

Inquiries of the nature of those above sketched, proceed upon the assumption that moral distinctions have their ground in the constitution of the world and of man's nature, and may be discovered by the exercise of human reason, as the other laws of the universe are. But practically, the rules of morality have, in almost all communities, been more or less dependent upon a belief in divine laws supernaturally revealed.

ETHIOPIA, the Biblical *Kush*. Originally, all the nations inhabiting the southern part of the globe, as known to the ancients; or rather, all men of dark-brown or black color, were called Ethiopians (Gr. *aitiō—ōps*, sunburned). Later, this name was given more particularly to the inhabitants of the countries s. of Libya and Egypt, or the upper Nile, extending from 10° to 25° n. lat., 45° to 58° e. long.—the present Nubia, Senaar, Kordofan, Abyssinia. The accounts which the ancients have left us with respect to this people are, even where they are not of an entirely fabulous nature, extremely scanty and untrustworthy, as both Greeks and Romans never got beyond Napata, 19° n. lat. We will just mention that from the Homeric age down to Ptolemy—who is somewhat better informed—these regions were peopled by Pygmies, Troglodytes (dwellers in caverns), Blemmyes (hideous men), Macrobia (long-lived men), etc., besides being divided into the land of cinnamon, myrrh, of elephant-eaters, fish-eaters, tortoise-eaters, serpent-eaters, etc. The only portion of ancient records which does contain something akin to historical accounts, is that which refers to Meroë, an island formed by the rivers Astaphus and Astaboras, tributaries of the Nile. There stood, from times immemorial, an oracle of Jupiter Ammon. This, and the central portion of the island, together with the extraordinary fertility of its soil, the abundance of animals, metals, etc., made it not only the chief place of resort for all the inhabitants of the adjacent parts, especially the numerous nomad tribes, but also the emporium for India, Arabia, Ethiopia, Egypt, Libya, and Carthage. Thus it grew so rapidly, that about 1000 B.C. it counted among the most powerful states of the ancient world; and about 760, having ever since Sesostris been tributary to Egypt, it succeeded, under Sabacus, in shaking off the Egyptian yoke, and continued, in its turn, to hold Egypt for about sixty years. During the reign of Psammetichus, 240,000 Egyptians settled in Meroë, which, the greater part of the immigrants being artisans, traders, etc., rose still higher. Many new cities were built, and the state was in the most flourishing condition, when it was conquered by Cambyes, about 530 B.C. He fortified the capital town, and called it Meroë. After the destruction of Thebes by Cambyes, most of the inhabitants of that city took refuge there, and made the country still more Egyptian. Ergamenes transformed its theocracy into a military monarchy, in the 3d century. Under Augustus, Meroë was conquered, and a queen Candace is mentioned as his vassal. Under Nero, nothing but ruins marked the place of this once powerful and highly civilized state. Up to this day, remnants of mighty buildings, covered with sculptures—representations of priestly ceremonies, battles, etc.—and half-defaced inscriptions hewn in rocks, besides rows of broken sphinxes and colossi, are frequently met with in those parts.

Their religion, art, form of government, and civilization, generally being—in their chief features at least—so identical with the Egyptian as to have given rise to the question, which of the two nations imparted their knowledge to the other, we will refer the reader for these points to the article EGYPT; and will proceed now to say a few words on the history of the descendants of the ancient Ethiopians—the inhabitants of the present Habesch, or Abyssinia—as we derive it from their poor and scanty native chronicles.

According to these, the son of Solomon and the queen of Sheba (Makeda as they, Balkis as the Arabian historians call her), named Menilehek, was the first king of the Ethiopians. Few kings' names occur up to the time of Christ, when Bazen occupied the throne. The missionary Frumentius (330) found two brothers (Christians) reigning—Abreha and Azbeha. During the time of the Greek emperor Justin (522), king Elezbaas destroyed the state of the Homerites in Asia, in order to revenge their persecutions of Christians; and was canonized. From 960 to 1300, another dynasty, the Zagoean, held the chief power, all the members of the Solomonic dynasty, save one, having been murdered by Esal, who made her son king. In 1300, Ikon-Amlak, a descendant of this one scion of the house of David, who had fled to Sheba, regained possession of the country, and made Sheba, instead of Axum, the seat of government. To this day, his family rules the country. Frequent revolutions within, more especially brought about by the religious squabbles imported by the Portuguese towards the end of the 15th c., and a host of enemies all around—the most formidable of whom were wild nomad tribes of the desert—forced the kings more than once to apply for foreign help; amongst others, that of the Turks in 1508; and the affairs of the modern state have at all times been anything but prosperous. Special mention is made of king Zara-Jakob (Constantine), 1434–68, who sent an embassy to the church-council at Florence; of Aznaf-Saged (Claudius), 1540–59, during whose reign Christoph. de Gama from Portugal lived in E., and made common cause with him against his enemies. This king also wrote a confession of faith, in which he defended his church both against Jesuits and the charge

of leaning towards Judaism. Socinios (1605-32) openly professed Roman views; but his son Facilides soon expelled the Jesuits and their friends from the country, and put an end to the Roman influence. Among these friends was also Abba Gregorius, later the friend of the great Ethiopologist Ludolf, who, having made his acquaintance at Rome, induced him to migrate to Gotha; where he also remained until his death. Under Joas (1753-69), the Gallas, a nomad tribe, hitherto the mightiest and most dangerous enemies of the Ethiopians, not only gained admission to all the offices in the state, but acquired almost absolute power. One of them (Susul Michael), holding the place of *râsh*, or prime minister and chief commander of the troops, proved a very great friend to Bruce, to whom he also intrusted the government of a province. The several provinces remained practically independent, each chief striving to subdue his neighbors, till in 1855, the chieftain afterwards known as Theodore (q.v.) attained supremacy. See also art. ABYSSINIA. The king resided but rarely in the city, and for the most part remained with his soldiers in the camp. His official name was *Negus*, or in full, *Negus Nagass Za-itjopja*, king of the kings of Ethiopia—alluding to the chiefs of the towns and provinces. The soldiers receive no pay, but rely on plunder; and have proved themselves able to fight bravely.

Emigrants, as were beyond doubt the earliest settlers in E., from the other side of the Arabian isthmus, it is but natural that the structure of their language, as well as that of their own bodies, should bear traces of their Shemitic origin. The reason of this emigration is contained in the very name of this language, which is called *Geez*—free, affording a most striking parallel to the designation *Frano*—French. Free places of habitation were what they came in search of. The name Ethiopian, or, as they call it, Ithiopiajan, they adopted from the Greeks at a very late period. This their oldest language, *Leshana Geez*, was suppressed by a royal decree of Ikon-Amlak, in the 14th c., and the Amharic adopted as the court language. Ever since, it has, with exception of the province of Tigré, where it is still spoken (with slight idiomatic changes), remained the *Leshana Mazhaf*, the language of books and of the church. It is exclusively used in writing, even of ordinary letters, and the educated alone understand it. Its general structure comes as close to that of the Arabic as a dialect can and must. A great many of its words are still classical Arabic; others resemble more the Hebrew and its two Chaldee dialects, the Aramaic and Syriac; others, again, belong to African dialects; and many, as the names of the months, are Greek. It has 26 letters, 22 of which bear the ancient Shemitic stamp, and exhibit the greatest likeness to the Phœnician, the common original alphabet; and seven vowels, including a very short *e*, which sounds precisely like the Hebrew Schêwa. These vowels are represented by little hooks, and remain inseparably attached to their respective letters; and as the Geez, unlike all its sister-languages, is never written without vowels, the alphabet becomes a syllabary with 182 characters. Another difference exists in its being written from left to right—a circumstance from which some have concluded that the Greeks introduced writing in E.; forgetting, in the first place, that Greek itself was frequently written from right to left, and that Zend, certain cuneiforms, hieroglyphs, etc., are likewise written from left to right. We cannot enter here into the grammatical minutiae of the language; we will only mention that out of the ten conjugations, eight are Arabic; that there is a double infinitive, but no participle and no dual; that the formation of the so-called plural, and of declension generally, point to that very remote period when the Hebrew and Arabic made use of the same grammatical processes. There are no diacritical marks employed in writing; the letters are not combined, and the words are separated by two dots.

Although there can be no doubt of the existence of a rich literature in a flourishing country like E. anterior to Christ, still, owing both to frequent internal convulsions, and the misguided zeal of the early Christian missionaries, who here and elsewhere considered it their first duty to destroy all the ancient records of which they could get hold, nothing but a few half-erased inscriptions have survived. The earliest existing document of post-Christian literature is a complete translation of the Bible, probably by Frumentius. See FRUMENTIUS. The Old Testament, probably a translation from the Alexandrine version of the LXX., consists of four parts: 1, the Law or Octateuchos (five books of Moses, Joshua, Judges, Ruth); 2, Kings; 3, Solomon; 4, Prophets, and two books of the Maccabees. The New Testament consists of—1, Gospels; 2, Acts; 3, Paulus; 4, Apostolus. A very peculiar book, Henoch, belongs also to the literature of the Old Testament. See ENOCH, BOOK OF. The New Testament comprises likewise another book, *Senodas*, containing the pseudo-Clementine or apostolical constitutions. The Ethiopians have a liturgy (*Kanon Kedaso*—Holy Kanon) and a symbolico-dogmatical work (*Haimanota Abau*—Belief of the Fathers), containing portions of homilies of the Greek fathers, Athanasius, Basil the Great, Chrysostom, Cyril, Gregory of Nyssa and Nazianzen. Besides these, they have martyrologies, called *Synaxar*. They employ in this their sacred literature a peculiar kind of rhythm without a distinct meter. Any number of rhyming lines forms a stanza, without reference to the number of words constituting the verse, or of verses constituting the stanza. They also use certain phrases as a refrain—not unlike the manner of the mediæval Hebrew Pizmon. See LITURGY, JEWISH. As to general literature, they have neither a written book of laws, nor a grammar of their own language, nor, in fact, anything worth mentioning, except a *Chronicle of Axum* and *Chronicles of Abyssinia*. They are very fond, however, of riddles, wise saws, and

the like, so fascinating to the eastern mind. They have a dictionary, but most of its explanations and translations are utterly wrong. No wonder the learned in Europe should have been sorely puzzled by such a language, and that they should, after long consideration, have pronounced it to be either "Chaldee" or "Indian," while Bruce held it to be the language of Adam and Eve. Potgen, a Cologne church-provost, happening to be at Rome at the beginning of the 16th c., there made the acquaintance of native Ethiopians, and became the first to enlighten the world on the nature of this occult language. After him came the Carmelite Jacob Marianus Victorius, from Reate, who wrote *Institutiones Linguae Chaldaee S. Ethiop.* (Rome, 1548), an entirely worthless book; then Wemmers, who in 1683 published an Ethiopian grammar and dictionary. The principal investigator, however, is Hiob Ludolf from Gotha, who, aided by the Abba Gregorius, before mentioned, and supported by his own extraordinary linguistic talents and indomitable energy, acquired such a power over this language, that notwithstanding the number of eminent Orientalists, such as Platt, Lawrence, Dorn, Hupfeld, Hoffmann, Roediger, Ewald, Isenberg, Blumenbach, etc., who have since worked in this field, his books, as re-edited by Dillmann, still hold the first place. It is hardly necessary to add, that the Ethiopian is one of the most important and indispensable languages to the Shemitic scholar, containing as it does a great many words and forms of a date anterior to the separation of the different Shemitic dialects. Among the most important Ethiopian books printed in Europe are the Psalms, edited with a Latin translation by Ludolf (Frankfort, 1701); the New Testament, in two volumes (Rome, 1548); the book of *Henoch* (Lond. 1840); *Ascensio Isaiae Vatis*, with a Latin translation by Lawrence (Oxford, 1819); *Didascalia*, or apostolical constitution of the Abyssinian church (Lond., 1834). Good treatises are Dillmann's *Grammar of Ethiopic* (Leip., 1857); Prætorius' *Grammar* (Halle, 1871); Schreiber, *Manuel de la langue Tigrâi* (Vienna, 1887). Since the English expedition to Abyssinia, the British museum possesses a larger number of Ethiopic MSS. than any other library.

ÆTHIOPS, or **ÆTHIOPS** (Gr. *aiḥō*, I burn, and *ops*, countenance; being of a black or burned countenance), is a term applied by the ancient chemists to certain oxides and sulphides of the metals which possessed a dull, dingy, or black appearance. Thus, *ethiops martialis* was the mixture of protoxide and peroxide of iron, known as the black oxide; *ethiops mineral*, or *ethiops narcoticus*, the black-gray sulphuret of mercury procured by triturating in a mortar a mixture of mercury and sulphur; and *ethiops per se*, was obtained by agitating commercial mercury for weeks or months, when the oxygen of the air slowly formed the black oxide of mercury.

ETHMOID BONE, THE (so called from *ēthmos*, a sieve), is one of the eight bones which collectively form the cavity of the cranium. It is of a somewhat cubical form, and is situated between the two orbits of the eye, at the root of the nose. Its upper surface is perforated by a number of small openings (whence its name), through which the filaments of the olfactory nerve pass downwards from the interior of the skull to the seat of the sense of smell, in the upper part of the nose. It consists of a perpendicular central plate or lamella, which articulates with the vomer and with the central fibro-cartilage, and thus assists in forming the septum or partition between the two nostrils. The lateral masses present a very complicated arrangement, and are so planned as to give in a small space a very large amount of surface, on which the filaments of the olfactory nerve are spread. In comparative anatomy, we find a direct ratio between the development of these masses and the acuteness of the sense of smell. See NOSE AND THE SENSE OF SMELL.

ETHNOGRAPHY, a term closely allied to ethnology (q.v.). Ethnography embraces the details, and ethnology the rational exposition, of the human aggregates and organizations known as hordes, clans, tribes, and nations, especially in the earlier, the savage, and barbarous stages of their progress. Both belong to the general science of anthropology (q.v.), or the natural history of mankind, being related to it as parts to a whole. Ethnography and ethnology, indeed, run up into anthropology as anthropology does into zoölogy, and zoölogy into biology. No very sharp line can be drawn between these two sciences themselves, their differences being mainly those between the particular and the general, between the orderly collection of local facts, and the principles according to which they may be grouped and interpreted. Ethnographers deal with particular tribes, and with particular institutions and particular customs prevailing among the several peoples of the world, and especially among so-called savages. Ethnologists bring simultaneously under review superstitions, legends, customs, and institutions which, though scattered in distant regions of the earth, have some common basis or significance. Ethnography and ethnology run as easily one into another as the two sections of general anthropology, viz.: 1, anthropology proper, as expounded by anatomists and physiologists, who deal with the different races of men, their elements, modifications, and possible origin; and, 2, demography, which, as constituted by the researches of Quetelet and his friends and disciples, as Farr, Galton, Guillard, and Bertillon, treats of the statistics of health and disease, of the physical, intellectual, physiological, and economical aspects of births, marriages, and mortality. Ethnography, ethnology, and anthropology are interwoven with philology, jurisprudence, archæology, geography, and the various branches of history. A fact may require to be investigated successively by linguists,

TYPES OF NATIONS.

anatomists, and mathematicians. In current language, ethnography and ethnology are often used indiscriminately; but if a distinction be made between them, an instinctive perception teaches us to speak of ethnographic facts and ethnological theories, of ethnographic literature and ethnological science—ethnology being related to ethnography as the wine to the grape.

ETHNOLOGY (Gr. *ethnos*, nation or race, and *logos*, discourse), a term applied to the science that treats of the persistent modifications of the human family or group; their most marked physical, mental, and moral characteristics when compared one with the other; their present geographical distribution on the globe; their history traced backwards to the earliest attainable point; and, finally, the languages of the various nations and tribes of mankind, existing or extinct, classified and compared, with the view, by their means, of determining the chief points of resemblance or dissimilarity among the nations of the earth. This science has gradually outgrown its name. It has been therefore deemed expedient to apply to it a term of wider and more neutral significance—namely, anthropology—derived from the Greek *anthropos*, man, and *logos*, a discourse. The term *ethnology* has this inconvenience, that it means no more than the “science of races,” and many authorities not only deny the existence of *races* of mankind, affirming that what are called races are in reality distinct species, but others argue that the term is as applicable to any races—e.g., races of dogs, or cats, or pigeons—as to the races of mankind. Hence the more exact and less sectarian term anthropology has been applied to denote the science that treats of the natural history of man. The science is divided into three branches—1. *Zoological anthropology*, which treats of the relations of man to the brute creation; 2. *Descriptive anthropology*, or ethnography, which classifies and describes the various divisions and subdivisions of mankind, and marks out their geographical distribution; 3. *General anthropology*, which M. Broca calls “the biology of the human race,” which, says a recent writer on the subject, “borrows and collates from all sciences facts and phenomena usually investigated in men as individuals, but which relate to men as groups of individuals,” and compares these with other facts relating to other groups of individuals. The study and bare description of a single negro’s skull is mere human anatomy; the study of a group of negroes’ skulls, and the description and comparison of their peculiarities with those of groups of skulls belonging to other races, would be a specimen of the work done by general anthropology.

No one can look at an Englishman, a red Indian, and a negro, without at once noticing the differences between the three, not only as regards the color of their skin, but the shape of the skull, the texture of the hair, and the character of the several features, as eyes, lips, nose, and cheek-bones. What strikes the ordinary observer chiefly is, of course, the difference of complexion; but the anatomist is fully as much interested in the shape of the skull. The first thoroughly scientific writer who endeavored to lay down a method of distinguishing between the different races of mankind by a comparison of the shape and size of the skull was Peter Camper, a distinguished Dutch anatomist of last century. He laid down a technical rule for ascertaining the *facial line*, and determining the amount of the *facial angle*, which he has thus described: “The basis on which the distinction of nations is founded may be displayed by two straight lines, one of which is to be drawn through the *meatus auditorius* to the base of the nose, and the other touching the prominent center of the forehead, and falling thence on the most advancing part of the upper jaw-bone, the head being viewed in profile. In the angle produced by these two lines may be said to consist not only the distinctions between the skulls of the several species of animals, but also those which are found to exist between different nations.” The heads of birds display the smallest angle, and it apparently becomes of greater extent “in proportion as the animal approaches more nearly to the human figure. Thus, there is one species of the ape-tribe in which the head has a facial angle of 42 deg.; in another animal of the same family, which is one of those simiæ most approximating in figure to mankind, the facial angle contains exactly 50 deg. Next to this is the head of the African negro, which, as well as that of the Kalmuck, forms an angle of 70 deg.; while the angle discovered in the heads of Europeans contains 80 deg. On this difference of 10 deg. in the facial angle, the superior beauty of the European depends; while that high character of sublime beauty which is so striking in some works of ancient statuary, as in the head of Apollo, and in the Medusa of Sissocles, is given by an angle which amounts to 100 deg.” The nearer the facial angle approached a right angle, the greater was held to be the intellectual development of the race. But M. Jacquart, of the natural history museum in Paris, showed that the facial angle in stupid people very often approached closely a right angle, and that, in the homogeneous population of Paris, the facial angle varied within wider limits than those Camper stated as a criterion of distinct species.

Camper’s method was abandoned for the vertical method, or *norma verticalis*, invented by Blumenbach. The object being to collect the greatest number of characteristics—“The best way,” says Blumenbach, “of obtaining this end is to place a series of skulls with the cheek-bones on the same horizontal line resting on the lower jaws; and then viewing them from behind, and fixing the eye on the vertex of each, to mark all the varieties in the shape of parts that contribute most to the national character,

whether they consist in the direction of the maxillary and malar bones, in the breadth or narrowness of the oval figure presented by the vertex, or in the flattened or vaulted form of the frontal bone." Founding upon this mode of admeasurement applied to a large collection of skulls of different nations, accumulated by himself, Blumenbach classified the human family into the following five varieties—viz., the Caucasian, Mongolian, Ethiopian, Malay, and American. In the first of these—which he made to include the Caucasians or Circassians proper, the Celts, the Teutons, the Shemites, the Libyan family, the Nilotic family, and the Hindustanic family—the skull is large and oval, the forehead expanded, the nasal bones arched, the chin full, and the teeth vertical. In the second—which embraces the Chinese and Indo-Chinese, the natives of the polar regions, the Mongol Tartars, and the Turks—the skull is oblong, but flattened at the sides, the forehead low and receding, the nose broad and short, and the cheek-bones broad and flat, with salient zygomatic arches. In the third—embracing the Negroes, Kafirs, Hottentots, Australians, Alforians and Oceanic Negroes—the skull is long and narrow, the forehead low, the nose broad and flat, the cheek-bones prominent, the jaws projecting like a muzzle, the lips thick, and the chin small. In the fourth—embracing the Malays and Polynesians generally—the skull is high and square, the forehead low, the nose short and broad, and the jaws projecting. In the fifth—embracing the American family and the Toltican family—the skull is small, with the apex high, and the back part flat, the forehead receding, the cheek-bones high, the nose aquiline, the mouth large, and the lips tumid.

This classification of the human family, with the added characteristics, under each class, of complexion, hair, and eyes, is, upon the whole, the most popular, Blumenbach having taken considerable pains to elaborate it, and present it to the world in a form acceptable to scientific inquirers. Later researches, however, have proved it to be not quite tenable. Thus, Cuvier reduced the five classes of Blumenbach to three—viz., the Caucasian, Mongolian, and Ethiopian, treating the Malay and American as subdivisions of the Mongolian. Jacquinot does the same. Dr. Prichard, who brought to the study of E. not only a large acquaintance with physiology, but a considerable knowledge of languages, admits a greater number of varieties than Blumenbach, but divides his Caucasian class into two independent groups, which he calls the Syro-Arabian or Semitic, and the Aryan or Indo-Germanic. Moreover, he objects to the term Caucasian, as representing the notion that mankind had their origin on mountain heights. For himself, Prichard holds with the view that it was rather on the banks of large rivers and their estuaries that the primitive nations developed themselves. "The cradles or nurseries of the first nations, of those at least who became populous, and have left a name celebrated in later times, appear to have been extensive plains or valleys, traversed by navigable channels, and irrigated by perennial and fertilizing streams. Three such regions were the scenes of the earliest civilization of the human race, of the first foundation of cities, of the earliest political institutions, and of the invention of the arts which embellish human life. In one of these, the Semitic or Syro-Arabian nations exchanged the simple habits of wandering shepherds for the splendor and luxury of Nineveh and Babylon. In a second, the Indo-European or Japetic people brought to perfection the most elaborate of human dialects, destined to become in after-times, and under different modifications, the mother-tongue of the nations of Europe. In a third, the land of Ham, watered by the Nile, were invented hieroglyphical literature, and the arts in which Egypt far surpassed all the rest of the world in the earlier ages of history." Dr. Prichard, in his well-known *Natural History of Man*, commences with a description of these three divisions of the human race, not as discriminated one from the other by the form of the skull, but as comprising nearly all the civilized communities, and indeed most of the tribes of people known to antiquity. "They were neither nomades nor savages, nor do they display in their crania either of the forms principally belonging to races in those different states of existence. They had all heads of an oval or elliptico-spherical form, which are observed to prevail chiefly among nations who have their faculties developed by civilization." As they cannot, however, by any means be made to comprehend all the types of man, after the Egyptians, he describes the great body of the nations of Africa, embracing tribes sunk in the lowest state of degradation; and after the Aryans, or Indo-Europeans, the people of high Asia, chiefly nomades, inhabiting vast steppes, and never rising in the scale of civilization beyond the condition of wandering shepherds, though in this capacity possessing some wealth, and acquainted with the use of clothing, tents, and wagons. "These classes of nations," he observes, "have different physical characters. Among the African savages we find the *prognathous* form of the head and all its accompaniments; and these traits display themselves in proportion to the moral and physical degradation of the race. In Northern Asia, most of the inhabitants have the pyramidal and broad-faced skulls." Referring our readers to the articles ARYAN RACE, EGYPT, and SEMITIC NATIONS respectively, for more detailed information on the subject of these three grand divisions of mankind, we shall here only notice Dr. Prichard's subdivisions of one of them, namely, the Aryan race.

The great Aryan or Indo-European race, which extends itself from the mouth of the Ganges to the British islands and the northern extremities of Scandinavia, divides itself, according to Prichard, into two branches—viz., the parent stock in Asia, and the colonies that it successively sent forth into Europe. The Asian branch comprises: 1. Hin-

dus; 2. Persians; 3. Afghans; 4. Baluchi and Brahui; 5. Kurds; 6. Armenians; and 7. Ossetines. The collective body of the European nations are now generally regarded as a series of colonies from Asia. The proof turns mainly on a comparison of languages; the ancient Sanscrit being regarded by the most competent judges as the parent not only of the Greek and Latin languages, but of the Teutonic, with its several ramifications of the Slavonic, Lettish, Lithuanian, and even Celtic. Dr. Prichard himself was the first to point out the affinity of the Celtic with the Sanscrit, Greek, Latin, and Teutonic, in a memoir published by him in 1831, on the *Eastern Origin of the Celtic Nations*. Later philologists have confirmed the view taken by him, and he is perhaps correct also in the conclusion, that they were the first great immigration of the Aryans into Europe, who were afterwards conquered, and their numbers considerably reduced by fresh advancing colonies from the same parent hive. But there are other nations or tribes of Europe which no efforts of the philologists have succeeded in tracing to the Aryan stock; such are the Lapps, Finns, Tschudes, and Ugrians of the n., and the Euskaldunes, now principally represented by the Basques in the west. To these, Dr. Prichard has given the appellation of Allophylian (Gr. *allos*, another, and *phleu*, tribe), thereby signifying their independence of the Aryan stock. The progenitors of these tribes were probably the inhabitants of Europe, prior to the first Aryan immigration.

After these several races, Dr. Prichard treats of the native tribes of the austral seas and the great Southern ocean, and finally, of the native inhabitants of America. In every case, he carefully describes the physical appearance or structure, the geographical *habitat*, history, and migrations (if any), the language, and the moral and psychical attributes of the nation or tribe immediately brought under notice. His information has generally been obtained from the best sources, and hence his works may be regarded as a storehouse of knowledge upon the subject of ethnology.

But both before and since Blumenbach and Prichard, there have been several classifications of the human race proposed, the simplest of which is perhaps that of Dr. Latham, into 1. Mongolidae; 2. Atlantidae; 3. Japetidae. This writer is properly regarded as the chief living exponent of the science of E. in this country. Following in the track of Prichard, and possessing, like him, a considerable acquaintance with physiology and history, he distances him altogether in the department of comparative philology. His contributions to the science of E., borrowed from this particular branch of study, are consequently of the highest value. But there is one important question, with respect to which the suffrages of the best philologists are rather with Prichard than with Latham—viz., the origin of the Aryan or Indo-European race. Prichard, as we have seen, refers it to Asia, while Latham claims it for Europe.

Retzius's classification is based on the idea that the psychical individuality of a race is expressed by brain-development as indicated by the shape of the skull. He divides races into—I. Dolichocephalic, or long-skulled races, where the length of the skull is due to a lengthening of the posterior lobes of the brain, and II. Brachycephalic, or short, broad-skulled races, in whom the comparative shortness of these lobes causes them to be more developed in breadth. These are subdivided, according to the form of the face, into (1) orthognathous, or straight-faced peoples; e.g., Europeans; and (2) prognathous, or races with projecting jaws, e.g., Negroes. This classification laid the foundation of ethnographic craniology. Zeune divides mankind into—(1) races with high skulls, e.g., Indo-Europeans; (2) races with broad skulls, e.g., Mongols and some Malay tribes; (3) races with long skulls, e.g., Negroes. Such classifications err in grouping under the same divisions races between which it is otherwise impossible to establish any consanguinity. Passing over the wild speculative classifications of the modern German materialistic school, a specimen of which is that of Carl Vogt, who, assuming the ape origin of mankind to be an indubitable fact, describes three great divisions of the human race in correspondence with the three species of anthropomorphic apes found in Asia, Africa, and America, the only other very recent classification with pretensions to scientific reasonableness, is that of Prof. Huxley, which is founded on the hair as a race-character. He describes two primary divisions—I. Ulotrichi, crisp or woolly-haired people, with skulls longer than they are broad (dolichocephalic), and with the skin-color varying from yellow to black. Negroes, Bushmen, and Malays are subdivisions of this great group. II. Leiotrichi, or smooth-haired people, subdivided into (1) the Australoid group, with "dark eyes, wavy black hair, and eminently long, prognathous skulls, with well-developed brow ridges;" (2) the Mongoloid group, e.g., Chinese, Tartars, Polynesians, and American aborigines; (3) The Xanthocroic group, fair, blue-eyed people, e.g., Slavs, Teutons, Scandinavians, and fair, Celtic-speaking nations; (4) The Melanocroic group, or pale-skinned people, with dark hair and eyes, e.g. the Iberians, or "black Celts" of Europe, the inhabitants of the Mediterranean coast and of western Asia—a group resulting probably from intermixture of the Australoid and Xanthocroic races. Under the Australoid group is classed such apparently unrelated races as the Australians, the Dekhan tribes in India, and the ancient Egyptians; and curiously enough, col. Lane Fox has since shown that, from resemblances in the weapons, implements, etc., in use amongst these very races, Prof. Huxley's apparently startling views as to their affinity are not at all improbable.

A more important question is, what do classifications classify—species or varieties? Prichard held that mankind sprang from one stock, and constituted one species. Exist-

ing diversities in form and physique in races he accounted for by the influence of food, climate, and other circumstances operating through a long series of years. Mr. Darwin's recent work on *Animals and Plants under Domestication* powerfully corroborates this view, for it demonstrates that within the limits of one admitted species of animal there may be produced, by the operation merely of artificial selection and hereditary transmission of peculiarities, diversities infinitely greater than those existing between the highest and lowest races of mankind. Then, again, the highest and lowest human races interbreed, and their offspring is fertile, which would hardly be the case if the parents were of different species. Some have held that the difficulties of migration from an original center of creation were too great to be compatible with the wide geographical distribution of mankind. Yet even the South Sea islanders—and in their case the difficulties alluded to must have been greater than in most others—may have come to their present abodes by migration; for Japanese mariners have sometimes by stress of weather been driven from their course, and cast on the shores of islands in the South Seas. This doctrine of monogeny, or original unity of the human race, is supported by Dr. Latham with arguments drawn from philology. Dr. Latham, taking it as a matter of fact that all the languages of mankind have had a common origin, argues from it in favor of an original unity of race. This common origin of languages, however, is a thing by no means proved. "The idea of an original language of the whole human race," says Dr. Waitz (*Introduc. Anthropologie Naturvölker*), "is by science now regarded as a chimera." Admitting that Klaproth, Fürst, and Delitzsch have taken great pains to establish an affinity between the Sanscrit and the Hebrew, M. Renan and other excellent authorities regard the attempt as unsuccessful, and, even were it otherwise, "the Chinese," says a late writer (Farrar, *Essay on the Origin of Language*), "must always remain a stumbling-block in the way of all theories respecting a primitive language. Radical as is the dissimilarity between Aryan and Semitic languages, and wide as is the abyss between their grammatical systems, yet they almost appear like sisters when compared with the Chinese, which has nothing like the organic principle of grammar at all. Indeed, so wide is the difference between Chinese and Sanscrit, that the richness of human intelligence in the formation of language receives no more striking illustration than the fact, that these languages have absolutely *nothing* in common except the end at which they aim. This end is in both cases the expression of thought, and it is attained as well in Chinese as in the grammatical languages, although the means are wholly different."

Having thus made the reader in some degree acquainted with the views of Drs. Prichard and Latham on the subject of E., we now proceed to inform him of the totally different views and conclusions of the American school of ethnology. This school was founded by the late Dr. Morton of Philadelphia, an erudite and active man of science, who labored for many years in forming a collection of human crania of all nations, and of ancient as well as modern ages, with the design of still further carrying out Blumenbach's researches into the varieties of mankind by a comparison of crania, according to the method he had proposed. This collection of crania was begun in 1830, and at the time of Morton's death in 1851, amounted to the large number of 918 human crania, to which were afterwards added 51; and it, besides, included 278 crania of mammals, 271 of birds, and 88 of reptiles—in all 1606 skulls, being the largest collection of the kind ever formed, and which, fortunately for the purposes of science, is now deposited in the museum of the academy of natural sciences at Philadelphia. Simultaneously with this accumulation of crania, Dr. Morton carried on his researches in E., not, however, in the restricted sense in which he began, following Blumenbach's classification, but availing himself of the latest discoveries of Prichard, and the other English and continental writers. One of the results of his labors was the publication, in 1839, of a handsome work, entitled *Crania Americana*, which was followed in 1844 by the *Crania Egyptiaca*, in the collection of which he had been much aided by Mr. G. R. Gliddon. "In this work," says his biographer, Dr. Patterson, "Morton found himself compelled to differ in opinion from the majority of scholars, in regard to certain points of primary importance." The great question of the unity or diversity of mankind in their origin was one that early forced itself upon his attention, and the conclusion at which he arrived, after much patient investigation, was in favor of the latter view. He was slow to publish any opinion on the subject, probably reserving it for a work upon which he was engaged, to be entitled the *Elements of Ethnology*. His opinion, however, was well known to his friends. In a note to a paper in *Silliman's Journal* for 1847, he says: "I may here observe that whenever I have ventured an opinion on this question, it has been in favor of the doctrine of primeval diversities among men; an original adaptation of the several races to those varied circumstances of climate and locality which, while congenial to the one, are destructive to the other; and subsequent investigations have confirmed me in these views." In a letter to Dr. Nott, dated Jan., 1850, he lays down the following proposition: "That our species had its origin, not in one, but in several or in many creations, and that these diverging from their primitive centers, met and amalgamated in the progress of time, and have thus given rise to those intermediate links of organization which now connect the extremes together. Here is the truth divested of mystery; a system that explains the otherwise unintelligible phenomena so remarkably stamped on the races of men." His latest utterance upon the subject is contained in a letter written to Mr. G. R. Gliddon, in April, 1851, only a fortnight before the writer's

TYPES OF NATIONS.

decease, which concludes as follows: "The doctrine of the original diversity of mankind unfolds itself to me more and more with the distinctness of revelation." His views upon this and other points of dispute among ethnologists have been since embodied in a remarkable work, entitled *Types of Mankind; or, Ethnological Researches based upon the Ancient Monuments, Paintings, Sculptures, and Crania of Races, and upon their Natural, Geographical, Philological, and Biblical History: illustrated by selections from the inedited papers of S. G. Morton, M.D., and by additional contributions from Prof. L. Agassiz, W. Usher, M.D., and Prof. H. S. Patterson.* By J. C. Nott, M.D., and G. R. Gliddon (Philadelphia, 1854). In this composite work, perhaps the most remarkable feature is the paper contributed by the celebrated naturalist, Prof. Agassiz, in support of Dr. Morton's theory as to the original diversity of the human races.

The paper by Agassiz is entitled, *Sketch of the Natural Provinces of the Animal World, and their Relation to the Different Types of Man.* It was drawn up by the writer from a conviction that much might be gained in the study of ethnography by observing the natural relations between the different races of man and the plants and animals inhabiting the same regions. The sketch given by him is intended to show, that "the boundaries within which the different natural combinations of animals are known to be circumscribed upon the surface of our earth coincide with the natural range of distinct types of man. Such natural combinations of animals circumscribed within definite boundaries are called *Faunæ*, whatever be their home—land, sea, or water." There are eight regions of the earth, according to Agassiz, each containing its own faunæ, and its own peculiar type of man; and his main conclusion from a consideration of these several faunæ is as follows: "That the diversity among animals is a fact determined by the will of the Creator, and their geographical distribution part of the general plan which unites all organized beings into one great organic conception; whence it follows that what are called human races, down to their specialization as nations, are distinct primordial forms of the type of man." Messrs. Nott and Gliddon, in their work quoted, appeal triumphantly to this theory of Agassiz in support of their view as to the primitive diversity of the races of mankind; and in a subsequent work, *Indigenous Races of the Earth* (Philadelphia, 1857), have inserted a further communication from the writer, in which, while he reiterates his formerly expressed opinion, that the races of man, so far as concerns their geographical distribution, are subject to the same circumscription as the other members of the animal kingdom, he observes: "Even if this fact stood isolated, it would show how intimately the plan of the animal creation is linked with that of mankind. But this is not all. There are other features, occurring among animals, which require the most careful consideration, inasmuch as they bear precisely upon the question at issue, whether mankind originated from one stock or from several stocks, or by nations. These features, well known to every zoologist, have led to as conflicting views respecting the unity or plurality of certain types of animals as are prevailing respecting the unity or plurality of the origin of the human races. The controversy which has been carried on among zoologists upon this point, shows that the difficulties respecting the races of men are not peculiar to the question of man, but involve the investigation of the whole animal kingdom—though, strange as it may appear, they have always been considered without the least reference to one another."

This theory of Agassiz, it must be stated, is very generally controverted, as likewise the opinions generally of Dr. Morton and the American school of E., partly on biblical, but chiefly on scientific grounds. Indeed, from the conflict of opinions as to the origin of the human race, if the solution of this question were the sole object of anthropology, the science might be said to be in a very unsatisfactory state. But this is not the case. The question at issue is one that may well be left in abeyance for the present. Without it, the field of inquiry is sufficiently wide, and is well cultivated by skilled laborers, who continually bring the product of their researches in physiology, geography, archæology, and comparative philology to enrich and fructify the newly turned-up soil.

Subjoined is a tabular view of the different races of mankind, according to the useful, if not absolutely perfect classification of Dr. Latham: (many prefer Huxley's).

I. MONGOLIDÆ.

Physical Characteristics.—Face broad and flat; frontal profile retiring or depressed; maxillary profile moderately prognathic or projecting, rarely orthognathic; eyes often oblique; skin rarely a true white, rarely a jet-black; irides generally dark; hair straight, and lank, and black, rarely light-colored, sometimes curly, rarely woolly. *Languages*—aplotic and agglutinate, rarely with a true amalgamate inflection. See *PALÆOGRAPHY; PHILOLOGY.* *Distribution*—Asia, Polynesia, America. *Influence upon the history of the world*, material rather than moral.

A. *ALTAIC MONGOLIDÆ*.—1. *Seriform stock*, embracing Chinese, Thibetans, Anamese, Siamese, Kambojians, Burmese, the Môn, and numerous unplaced tribes. 2. *Turanian stock*, embracing the Mongolian branch, the Tungusian branch, the Turk branch, and the Ugrian branch.

B. *DIOSCURIAN MONGOLIDÆ*.—1. Georgians. 2. Lesgians. 3. Mizjeji. 4. Irôn. 5. Circassians.

C. *OCEANIC MONGOLIDÆ*.—1. *Amphinesian stock*, embracing Protohesians, Polyne-

sians, Malegasi (?). 2. *Kelanonesian stock*, embracing the natives of New Guinea, New Ireland, Solomon's Isles, Louisade, New Caledonia, Australia, and Tasmania.

D. HYPERBOREAN MONGOLIDÆ.—1. Samœids. 2. Yeniseians. 3. Yukahiri.

E. PENINSULA MONGOLIDÆ.—1. Koreans. 2. Japanese. 3. The Ainos. 4. Koriaks. 5. Kamskadales.

F. AMERICAN MONGOLIDÆ.—Embracing the various native tribes of North and South America.

G. INDIAN MONGOLIDÆ.—1. Tamul. 2. Pulinda. 3. Brahui. 4. Indo-Gangetic. 5. Purbutti. 6. Cashmirian. 7. Cingalese. 8. Maldivian.

II. ATLANTIDÆ.

Physical Characteristics.—Maxillary profile projecting; nasal, generally flat; frontal, retiring; cranium, dolichocephalic; the parietal diameter being generally narrow; eyes rarely oblique; skin often jet-black, very rarely approaching a pure white; hair crisp, woolly, rarely straight, still more rarely light-colored. *Languages*, with an agglutinate, rarely an amalgamate inflection. *Distribution*, Africa. *Influence on the history of the world*, inconsiderable.

A. NEGRO ATLANTIDÆ.—Embracing various negro tribes.

B. KAFFRE ATLANTIDÆ.—Kaffre tribes, etc.

C. HOTTENTOT ATLANTIDÆ.—1. Hottentots. 2. Saabs. 3. Dammaras.

D. NILOTIC ATLANTIDÆ.—1. Gallas. 2. Agows and Falasha. 3. Nubians. 4. Bishari. 5. M'Kuafi, etc.

E. AMAZIRGH ATLANTIDÆ.

F. EGYPTIAN ATLANTIDÆ.

G. SEMITIC ATLANTIDÆ.—1. Syrians. 2. Assyrians. 3. Babylonians. 4. Beni Terah (Edomites, Jews, Samaritans, etc.). 5. Arabs. 6. Ethiopians. 7. Canaanites, etc.

III. JAPETIDÆ.

Physical Characteristics.—Maxillary profile but little projecting; nasal often prominent; frontal sometimes nearly vertical; face rarely very flat, moderately broad; skull generally dolichocephalic; eyes rarely oblique; skin white or brunette; hair never woolly, often light-colored; irides black, blue, gray. *Languages*, with amalgamate inflections, or else anaplotic; rarely agglutinate, never aptotic. *Distribution*, Europe. *Influence on the history of the world*, greater than that of either the Mongolidæ or the Atlantidæ, moral as well as material.

A. OCCIDENTAL JAPETIDÆ.—Kelts.

B. INDO-GERMANIC JAPETIDÆ.—1. *European class*, embracing Goths, Teutons (Mæso-Goths, High and Low Germans, Franks), Scandinavians, Sarmatians, Slavonians (Russians, Servians, Illyrians, Bohemians, Poles, Serbs), Mediterranean Indo-Germans (Hellenic branch, Italian branch). 2. *Iranian class*, embracing Persians, Kurds, Beluchi, Patans (Afghans), Tajiks, Siaposh, Lugmani, Dardoh, Wokhan. 3. *Unplaced stocks*, Armenians, Iberians, Albanians. 4. *Extinct stocks*, Pelasgi, Etruscans, populations of Asia Minor.

ETHYL (symbol, C_2H_5) is the radical which forms the starting-point of the family group, of which ordinary ether and alcohol are members.

| | |
|----------|---------------------------------|
| Ethyl, | C_2H_5 . |
| Ether, | $(C_2H_5)_2O$, oxide of ethyl. |
| Alcohol, | C_2H_5OH , hydrate of ethyl. |

Ethyl has not been prepared in the free state, but a polymeric body called diethyl, $C_2H_5 \cdot C_2H_5$ or C_4H_{10} , is formed by acting upon iodide of ethyl by granulated zinc, when it is liberated as a colorless, inflammable gas, of an agreeable odor, insoluble in water, but soluble in alcohol.

ETHYLAMINE is a substance strongly resembling ordinary ammonia or hartshorn in odor and other properties. It is found in coal-tar, in the oil obtained during the destructive distillation of bones, in the gases evolved during putrefaction, and may be produced by certain complicated chemical processes. E. is a mobile liquid of specific gravity 696 (water = 1000), and boils at $66^\circ F.$ ($18.9^\circ C.$). It has a strong ammoniacal odor, has an alkaline action with coloring matters, forms white fumes with strong acids, and in composition is analogous to gaseous ammonia, NH_3 or $NHHH$, with one of the atoms of hydrogen replaced by ethyl, C_2H_5 , and is represented by the symbol $C_2H_5 \cdot NH_3$. Like ammonia, it forms salts with acids.

ETHYLENE, **ETHENE**, or **BICARBURETED HYDROGEN**. See **OLEFIANT GAS**.

ÉTIENNE, St., an important manufacturing t. of France, in the department of Loire, is situated on both banks of the Furens, an affluent of the Loire, in the center of a valuable and extensive coal-field, 30 m. s.s.w. of Lyons by rail, and about 288 m. s.s.e. of Paris. It is surrounded by coal-mines, is seated upon coal-deposits, and has galleries driven even beneath its streets. The stream on which the town is built furnishes invaluable water-power to move its machinery, and its waters are also of great use for tempering iron and steel. The old town of St. E. is badly built, and the new town, which has sprung up very quickly, is destitute of architectural harmony. The newer

houses are built of a fine white sandstone, and are frequently five and six stories in height; but they rapidly become tarnished and begrimed by the perpetual cloud of coal-smoke which hangs over the town. The most noteworthy building is the Hôtel-de-Ville, which contains the *Musée Industriel*, with specimens of the manufactures of the town, and of the minerals and fossils of the neighborhood. St. É. is famous for its manufactures of ribbons and firearms. The ribbon-manufactures comprise velvet and silk ribbons, trimmings, etc., the annual output being very extensive. They are unrivaled in elegance of design, and in richness and delicacy of color, and are exported to all parts of the world. There are extensive private manufactories of firearms, besides an imperial firearms manufactory, which supplies most of the muskets of the French army. St. É. has also extensive manufactures of bayonets, scythes, nails, saw-blades, foils, anvils, vices, files, naval and railway materials, and also of silks, velvets, lace, embroidery, muslins, glass, leather, chemicals, chocolate, india-rubber, sabots, paste-board and paper. The coal-field on which St. É. is situated, is very productive. On the 1st Jan., 1856, St. É. was constituted the capital of the department in place of the town of Montbrison. St. É. arose originally from a castle built in the 10th c. by the counts of Forez. It increased greatly in the 15th c., and in 1771 it had 20,000 inhabitants; in 1851, it had 49,614 inhabitants; in '72, it had 80,526; in '76, 117,537 inhabitants; and in '96, 136,030.

ETIQUETTE (Fr. a ticket, supposed to be from the Celtic *tocyn*, a little piece or slip—a token). Originally, E. signified a little piece of paper affixed to a bag or other object to indicate its contents. The word came probably to possess the secondary meaning which we now attach to it, of the forms or decorums observed in the intercourse of life, more particularly on state occasions, from its having been customary to deliver such tickets, instructing each person who was to take part in the ceremony as to the part which he was expected to play. The cards which are still delivered to the mourners at funerals, and those on which the order of the dances is set forth at balls and evening parties, are of this nature. Popular publications are constantly issuing from the press for the purpose of teaching E., or the rules of behavior in good society. They will, for the most part, be found far less trustworthy than the promptings of nature, where the individual possesses a reasonable amount of reverence for others, and respect for himself. Yet there are certain conventionalities which can only be learned by instruction of some kind, or by observation, and the observation may be attended with unpleasant circumstances.

ETIVE, a sea-loch in the n. of Argyleshire, running inland from the firth of Lorne, 20 m. e. and n.e., with a breadth of a quarter to three miles. It is bordered by granite in its upper part, and by trap in its lower. Near its mouth there is mica-slate on the n. side, and permian strata on the south. The river Awe, the outlet of loch Awe, falls into the loch at the bend, where also is the ferry of Bunawe, and the small river Etive falls into it at its n.e. end. The loch abounds in salmon. The scenery around the upper half of the loch is grand and romantic. To the e. rise Ben Cruachan, 3,670 ft., and Ben Starive, 2,500 ft., and to the n. Ben Mahrgage. The loch admits small coasting-vessels. Ardchattan priory, founded in the 13th c., on the site of a monastery of the 6th or 7th c., is now in ruins. Connel ferry, in the lower part of the loch, and near a vitrified fort, is only 680 ft. broad, and is a very turbulent cataract, 3 or 4 ft. high at half-tide, caused by a sunken reef of rocks, partly bare at low water. At the s. side of the mouth of loch E., 3 m. n. of Oban, on a projecting conglomerate rock 10 to 30 ft. high, are the ruins of Dunstaffnage castle, the ancient stronghold of the Macdougals, a building in what is called the Edwardian style of the end of the 13th or beginning of the 14th c., with walls 400 ft. in circumference, 30 to 50 ft. high, and 10 ft. thick, and with three round towers. Dunstaffnage is supposed by some to have been the seat of the Dalriadic Scottish monarchy (see DALRIADA), and from this place the famous slab or stone of destiny (*Lia Fail*), now in the coronation-chair, Westminster abbey, is said to have been taken in 843 by Kenneth Macalpine to Scone, whence Edward I. removed it to London.

ETNA, or **ÆTNA** (now MONTE GIBELLO), is the largest volcano in Europe. It is an isolated mountain, situated on the eastern coast of Sicily, and cut off from the chain of mountains which run parallel with the northern shore of the island, by a small valley, through which flows the Alcantara, and from the southern chain by a larger valley, which forms the basin of the Giaretta. Its eastern side rises directly from the Mediterranean, 30 m. of coast being formed by the streams of its lavas. Its base is almost 90 m. in circumference, and from this it rises like an immense cone to the height of 10,874 feet.

The history of E. does not carry us far back geologically; an active volcano in the later portion of the tertiary period, it continues still to pour forth materials; and the ejected ashes, dust, and lapilli, together with the streams of molten lava, have, in the course of untold ages, built up this immense mountain. One central crater has been the prevailing outlet for these materials, and they have consequently arranged themselves into one central and dominant mound—the cone-shaped E.; but innumerable secondary and surrounding craters, each forming, by its ejected matter, an external smaller cone, exist on Etna. Many of these, in the progress of the growth of the mountain, have been covered and hid by the more recent eruptions. Eighty of them may be

counted surrounding the upper portion of E., many being hills of considerable altitude, but all of them appearing only as trifling irregularities when viewed at a distance as subordinate points of so imposing and colossal a mountain. Seen from the summit, they present a beautiful aspect; some bare and barren, others covered with the dark and somber pine, or with the gayer and more varied foliage of the oak, the beech, and the hawthorn, and all arranged in picturesque groups of various heights and sizes. But the most remarkable feature in E. is the Val del Bove, an immense gully excavating the eastern flank of the mountain, 5 m. across, and surrounded by nearly vertical precipices from 1000 to 5,000 ft. high, on which are shown sections of innumerable lava-streams and beds of scoriæ, traversed by highly inclined dikes. It has a singularly dreary and blasted appearance.

The summit of E. rises considerably above the line of vegetation, and consequently presents, except where covered with snow, a dreary waste of black lava, scoriæ, and ashes, in the center of which, in a desolate plain, rises the crater-bearing cone. This is called the desert region. It is followed by 6 or 7 m. of the woody region, in which luxuriant forests of pine, oak, beech, poplar, and hawthorn abound, together with rich pasturage for herds and flocks. A varying breadth of from 2 to 11 m. of cultivated region surrounds the base of Etna. Its great products are corn, oil, wine, fruit, and aromatic herbs.

The first recorded eruption of E. took place 476 B.C. The most remarkable that have occurred since are the following: 1169 A.D., when Catania and 15,000 of its inhabitants were destroyed; 1527, in which two villages and many human beings perished; the eruption which continued at intervals from 1664 to 1673, and destroyed many villages with their inhabitants. Numerous chasms were formed at this time; from one several miles long and 4 or 5 ft. wide were emitted a bright light and strong sulphurous vapor; from another, black smoke and quantities of stones were given out; and from others, streams of lava. In 1673, an immense volume of salt (?) water rushed down the mountain: by some, it is supposed to have been ejected from the crater, but it is more probable that it arose from the sudden melting of the snows which covered the summit of the mountain. A very great eruption took place in 1852. Immense clouds of ash-gray dust were ejected. From two new mouths on the eastern flank there issued vast torrents of lava, one of which was 2 m. broad, and at one time as much as 170 ft. deep. The next outbreak, in 1864-65, was of trifling importance. That of May, 1879, was much more violent; the clouds of smoke and showers of ashes and scoriæ being followed by the ejection of a torrent of lava from 200 to 300 ft. in width, which desolated a large tract of highly cultivated land.

The minerals peculiar to volcanic rocks occur at E., such as chrysolite, zeolite, selenite, alum, niter, vitriol, copper, mercury, and spicular iron.

ÆTOLIA. See **ÆTOLIA.**

ETON, a t. in the S. of Buckinghamshire, on the left bank of the Thames, 42 m. s.s.e. of Buckingham, and 22 m. w.s.w. of London, near the Slough station of the Great Western railway. It lies opposite to Windsor, in Berkshire, with which it is connected by a bridge over the Thames. Though in separate counties, these two towns really form one. E. chiefly consists of one long well-paved street, and is mainly dependent on the college. Pop. '91, 2499, exclusive of the Eton boys.

ETON COLLEGE is one among the most famous educational establishments in England. It was founded in 1440 by Henry VI., under the title of "The College of the Blessed Mary of Eton beside Windsor." The original foundation consisted of a provost, 10 priests, 4 clerks, 6 choristers, 25 poor grammar-scholars, a master, and 25 poor infirm men. The king provided for the establishment out of his own demesne lands and the estates of certain alien priories. A supplementary charter was granted in 1441, in which year also the college buildings were commenced. Henry was very solicitous that the work should be of a durable kind. Some of the buildings were finished in 1443, and were handed over by the royal commissioners to the provost, clerk, and scholars. Political troubles of various kinds retarded the completion of the buildings till 1523. Bishop Waynflete was the first head-master, and afterwards a munificent supporter of the college. The institution passed through much peril in the reign of Edward IV., and again in the time of the commonwealth; but it surmounted the dangers, and the increasing value of its estates brought in a large income.

The original foundation has been greatly modified under the public schools act, 1868. It now consists of a provost and 10 fellows, who constitute the "governing body," 2 chaplains or conductors, and 70 scholars. The members of the governing body are nominated by the universities of Oxford and Cambridge, and other learned and responsible electors. Several valuable scholarships at King's college, Cambridge, are filled up every year from among the scholars by competitive examination. There are also other scholarships and prizes open to all the members of the school, such as the Newcastle and Tomline scholarships, and prizes for modern languages, founded by the late prince consort. The scholars are lodged within the college walls.

The main portion of the establishment, however, numbering nearly 900, consists of the *oppidans*, students who live out of the college, and whose friends pay liberally for their education. The tuition is the same for them as for the *collegers* or scholars.

There are an upper and a lower school, managed by the head master and lower master, with a large staff of assistants. Considerable discussion has taken place within the last few years concerning the kind of education received at Eton, the cost at which it is obtained, and the enormous incomes derived by some of the officials. The course of education is still somewhat of the mediæval character, which regards Greek and Latin as the basis of all good education; but mathematics and natural science, under recent regulations of the governing body, receive a large share of attention.

The chief buildings of the college consist of the chapel, the hall, the library, the schools, the provost's and master's apartments, and the lodgings of the fellows, surrounding two quadrangles; together with the boys' library and sleeping apartments, in a cluster called the new buildings, attached to the northern side of the older group. The chapel is mostly of stone, the other buildings of brick; and the effect of the whole is very picturesque, as seen from the terrace of Windsor castle, on the other side of the Thames. The chapel is an especially beautiful object.

ETOWAH, co. in n.e. Alabama, crossed by the Coosa river, and the Louisville and Nashville and other railroads; 510 sq. m.; pop. '90, 21,926, includ. colored. The surface is rough, with extensive forests and fertile soil. Productions, corn, cotton, wheat, etc. Co. seat, Gadsden.

ETRETAT, a watering place on the English channel in Seine-Inférieure, Normandy, about eighteen miles n.e. of Havre. Pop. 2000.

ETRU'RIA, TYRRHĒ'NIA, TU'SCIA, designated, at a period anterior to the foundation of Rome, nearly the whole of Italy, together with some of its most important western islands. Its northern part, from the Alps to the Apennines, was known under the name of Etruria Circumpadana; its southern, from the Tiber down to the gulf of Pæstum, or, according to some, to the Sicilian sea, under that of Etruria Campaniana; while the central portion, bounded on the n. by the Apennines and the river Macra, s. and e. by the Tiber, and w. by the Tyrrhenian sea, was called Etruria propria. The two first, however, did not long remain Etruscan territory, but were either reconquered by the surrounding tribes to whom they had originally belonged, or fell into the hands of new immigrants. No historical records of that brief period of any moment having yet come to light, they do not claim our attention; while Etruria proper, scanty though our information about it still be, deserves our interest in the highest degree. For its physical features, we refer the reader to Tuscany, Lucca, and the Transiberine portion of the present papal dominions; and have only to remark, that vast expanses of that country, which now are either covered with deep forest, or are shunned on account of the malaria, were in those times fruitful, densely peopled regions. For political, or rather administrative purposes, Etruria proper was divided into twelve sovereign cities, or rather cantons, among which the most important were Tarquinii (Corneto), the cradle of the royal family of the Tarquins, who at one time wielded the scepter of Rome; Cære (Agylla, Cervetri), which, during the war of Rome with the Gauls, offered a refuge to the Roman Flamen Quirinalis and vestal virgins; Veii, the greatest and most powerful city of Etruria, with 100,000 inhabitants, which carried on seven wars with Rome; Clusium (Kamars, Chiusi), the chief of which, Porsena, as principal commander of the Etruscan troops, dictated a humiliating peace to Rome after she had expelled the Tarquins; Perugia (Perugia), destroyed in the Perusian civil war (40); Arretium (Arezzo), birthplace of Mæcenas. Of other not sovereign places may be mentioned Luca (Lucca), Pisæ (Pisa), on the Arnus, with the Portus Pisanus, now Leghorn, and Florentia (Firenze, Florence), on the Arnus.

To what nation the inhabitants—called Etruscans (=Exteri, strangers) or Tuscans in the Roman, Tyrrheni or Tyrseni (*Turrēnoi*, *Tursēnoi*) in the Greek, and Rasena (Tesne Rasne) in their own language—originally belonged, and what country they came from, is a question which was debated many hundred years before Christ, and is not settled yet. All the most ancient writers, save one of the most trustworthy, Dionysius of Halicarnassus, implicitly follow Herodotus, who—confounding them, perhaps, as is his wont, with the Lydian *Turrēnoi*, or inhabitants of the city of Tyrrha—pronounces them to be Lydians, although there is not the slightest similarity between these two nations, and although Xanthus, the Lydian historian, knows nothing whatever about a fabled famine of eighteen years' duration in Lydia, followed by an immigration to Italy under a prince Tyrrhenus. Dionysius himself offers no opinion; he calls them an indigenous race—which means nothing; and it is surprising that some modern investigators should, despairing of a rational solution of the old riddle, have fallen back upon this evasive theory of "autochthons." Thucydides, in first mixing up the Torthebian pirates with the Pelasgian filibusters, gave rise to the most hopeless confusion about their very name. As to the innumerable theories and hypotheses that have been put forward since his day, we will only mention that while Ciampi and Collar hold them to be of Slavonic origin, Prérêt calls them Celts; Micali, Albanese; Lami, Pfizmaier, and Stickel, Semitics; and others variously make them Goths, Scandinavians, Basques, Assyrians, Phenicians, Egyptians, and Armenians. The most rational and generally accepted opinion is that of Niebuhr—modified more or less by Ottfried Müller, Lanzi, Lepsius, Steub—of their being, when they first appear in history, a mixture of an eastern tribe, which had settled for a while in the Rætian Alps (the Tyrol of to-day), and Pelasgians, whom

they found in their new Italian seats; these latter having, in their turn, since their immigration, mixed with the Umbrians, the oldest historical inhabitants of those parts. But, as we said before, this is only the most rational opinion that rose out of an ocean of wild speculation: so far from any authentic proofs having been brought forward in its support, the question stands to-day precisely where it stood when Dionysius wrote:—"The Etruscans do not resemble any people in language and manners."

Immense as was their influence on Roman, and, in fact, on European civilization, very little is known with respect to their political history. Chiefly cultivating the arts of peace, they still seem, long after their heroic period, to have been powerful enough to scare away any invader, and this probably is the reason why historians have so little to record of them; but their decline may be said to stand in an inverted ratio to the rise of Rome. The 7th and earlier half of the 6th c. B.C. had been the most powerful and flourishing epoch of the Etruscan state in its widest sense—which then probably had been in existence for four or five hundred years. Whether they had put their Tarquinius as governors over conquered Rome, or whether, on the contrary, the reign of this Etruscan family would denote the subjugation of Southern Etruria by Rome herself, is not quite clear; but the expulsion of the last Roman king, Tarquinius (Tarchon), called Superbus, was followed, about 507 B.C., by a war between the Etruscans, under Porsena of Clusium, and the Romans, which, although ending in a most ignominious peace, dictated within the walls of Rome, did not bring about the restoration of the Tarquinian dynasty. From the wars between Veii and Rome, which began in 486, and ended—interrupted only by an occasional armistice—395 B.C., with the destruction of Veii, dates the gradual but sure extinction of Etruria as an independent state. The Gauls advancing from the north, the Etruscans were forced to conclude a forty years' truce with their adversaries at any price; but these over, and the Romans being engaged with the Samnites, the Etruscans recommenced the hostilities more fiercely than ever. In the course of this last war, the Romans succeeded, 309 B.C., under Q. Fabius Maximus, in twice defeating them, and Fabius crossed the Ciminian forest—the frontier sacred from time immemorial; and when, 283 B.C., P. Cornelius Dolabella had beaten both them and their Gallic auxiliaries in a decisive and sanguinary battle at the Vadimonian lake, Etruria became a Roman province; and about two hundred years later, the Lex Julia conferred upon her inhabitants, as a reward for their fidelity, the right of citizenship. Up to that time, they had succeeded in keeping up their own singularly distinct creed, customs, traditions, language—their nationality, in fact; when Sulla, 82 B.C., infuriated by the part they had taken against him, liberally bestowed great portions of their land upon his veterans; and some fifty years later, Octavianus planted his military colonies there. This wrought and completed the transformation of that mysterious conglomeration of heterogeneous races and tribes, hitherto called Etrurians, into Romans. Once more, well-nigh 2,000 years after its extinction, the kingdom of Etruria (Hetruria) rose before the eyes of the world. The peace of Luneville re-created it, and conferred it on the hereditary prince, Louis of Parma; after whose death, his widow, the infanta Louisa of Spain, administered the government for their son, Charles Louis, up to 1807, when it became a French province. From 1809, it again bore the name of the Grand Duchy of Tuscany; and to TUSCANY—which in our days forms a province of the Italian kingdom, as it did of yore—and to ITALY, we refer for its modern history.

We have spoken above of twelve cities as forming the confederacy of Etruria proper. Similar confederacies of twelve cities were established, independently of each other, in the two other Etrurias. The cities themselves, however, cannot be fixed now in all cases. From the fact of more than twelve autonomous ones being recorded in Etruria proper, it would appear that some among these twelve confederates, or *populi*, possessed more than one capital city, each *populus*, however, being limited to one representative vote in the general council. The members of the confederacy were bound to appear regularly at an annual religious assembly near the temple of Voltumna, a locality which we are as yet unable to point out. Here great fairs were held for the people; common operations of war being discussed by the *principes*, and a general-in-chief for the ensuing year elected from their number. Each city or canton, in the earlier times at least, had a king (Lucumo, Lauchme=Inspired), chosen for life, who at the same time acted as high-priest; and a hereditary nobility, which alone was eligible to the higher offices of state. Next to them, in the political and social scale, came the people, properly so called—free, not subject personally to the nobility; lowest stood a great number of clients or bondmen, probably the descendants of subjected original inhabitants. On the whole, the federal interdependence between the cities was far from close. Single cities carried on wars in which the others took no part; and when the confederacy resolved on general action, there were always some members which, for some reason or other, stood aloof. It appears from this that the Etruscan constitution was analogous to the Greek and Roman in their earliest stages: the community develops itself into a *polis* or city, chooses a head, or rather high-priest, and enters into a more or less intimate alliance with its neighboring cities; but, beside that king of its own, recognizes a common chief only in time of war.

The Etruscans were, as a people, less warlike than any of their neighbors, especially the Romans, and conspicuous is their want of anything like cavalry. Theirs was also the un-Italic custom of hiring soldiers, and their energies seem principally to have been

directed to the more profitable occupations of trade and agriculture. One of the chief articles of their commerce was amber, which Germans brought from the Baltic to Etruria Circumpadana, whence it was conveyed to Greece by sea. In the western parts of the Mediterranean, they were formidable as pirates; while they were welcomed by the Carthaginians and the Greeks of Magna Græcia, as importers of indigenous products of nature and art, which they exchanged for the wealth of the east and south. That their commerce within Italy must have been very extensive, appears from the fact, that all the states of central Italy adopted their system of coinage, based, like their tables of weights and measures, and many of their political institutions, on the duodecimal system.

The striking contrast between the Etruscans and their Italic and Greek neighbors, which appears in the short thickset frames, the large heads and bulky extremities of the former, and the slender limbs and graceful harmony in the whole structure of the latter, and which runs with equal distinctness through the intellectual lives of the three nations, manifests itself nowhere with greater power than in their religions. Equally distant from the abstract, clear rationalism of the Latins, and the plastic joyfulness of Hellenic image-worship, the Etruscans were, as far as their dumb fragments show—for what we find on them of human words we do not understand—chained in a dark and dotard mysticism, such as a blending of a half-forgotten eastern symbol-service with barbarous religious practices of northern savages, grafted upon archaic Greek notions, might produce. In their pantheon, the predominance belongs to the evil, mischievous gods; their prisoners are welcome sacrifices to the heavenly powers; they have no silent depths where the “good spirits” of their departed dwell, but a hell of the most hideous description, and a heaven where permanent intoxication is the bliss that awaits the virtuous. They divide their gods into two classes, and they place them in the most northern, and therefore most immovable point of the world, whence they can best overlook it. The upper section is formed by shrouded, hidden gods (*Involuti*), of uncertain number, who act awfully and mysteriously, and twelve lower gods of both sexes, called *Consentes*, *Complices*. *Tinia* (*Zeus*, *Jupiter*) is the chief of these latter, and stands between the two divisions of the gods, receiving orders for destruction from the upper ones, while the lower ones form his ordinary council, and obey his behests. Nine of these (*Novensiles*) hurl lightnings at various times and with peculiar effects. The three of these deities which seem to have been the principal objects of worship were *Tinia* himself, armed with three different kinds of lightning, *Cupra* (*Hera* or *Juno*) and *Menrfa* (*Minerva*, *Pallas Athene*). Gods most peculiarly Etruscan are *Veiovis*, an evil *Jupiter*, whose thunder-bolts have the power to deafen, and *Nortia*, the goddess of fate, also called *Lasa Mean*. Besides these, they put a host of demons over the different portions of the creation:—the heavens, the earth, and the lower regions (*Penates*, *Lares*, and *Manes*). Their deities have generally wings; and before the Assyrian bulls had come to light, some antiquaries established from this a connection with the Hebrew winged cherubim. Characteristic in the highest degree is their “disciplina” or art of “divination.” This had been revealed by *Tages*, a grandson of *Jupiter*, who was dug out near *Tarquinius*, in the shape of a child-like dwarf with gray hair—a most striking caricature of these both childish and senile practices—and who died immediately after having communicated these mysteries. They were at first the property of the noble families; but in the course of time, as others were initiated, and schools for priests were founded, these mystical and awe-striking teachings came to be written down. It is saddening to observe here again in what monstrous insanities the spirit of man occasionally revels, and that, too, in the province of what is noblest and highest—religion. The “disciplina” was developed into an exact science, fully as minutely and casuistically sharpening its points and splitting its hairs as *Hindu* or *Mohammedan* theology would. It taught what gods hurled the different kinds of lightning; how, by the color and the peculiar quarter of the sky, the author of the bolt might be recognized; whether the evil denoted was a lasting or a passing one; whether the decree was irrevocable or could be postponed; how the lightning was to be coaxed down, and how it was to be buried. This was the specialty of the *Fulgurales*. The *Haruspices* had as their share the explanation of portents, prodigies, monsters, the flight and cries of birds, the entrails of sacrificial animals; while others ministered in the holy rites at the foundation of cities, the building of gates, houses, etc. Their ceremonies (a word derived from their town *Cære*) were endless and silly, but the show and pomp with which their priests knew how to surround these juggleries and from which the Romans largely borrowed, made them acceptable in the eyes of the herd; and although Rome herself, with all her augurs, called Etruria “the mother of superstition,” there was a certain odor of tithes and fees about these rites which made many anxious to “preserve religion in its primeval purity.”

In the entire absence of anything like a genuine Etruscan account, even the outlines of the relation between their religion and that of the Greeks on the one hand, and the Romans on the other, are exceedingly difficult to trace; so much, however, is certain, that they adopted and assimilated many points of archaic Greek theology, and clothed them in a garb of their own, and that this process was gone through and repeated still more completely by the Romans, in their turn, with respect to the religious notions of

the Etruscans. The articles on Greek and Roman religion will furnish further information on this point.

The high degree of civilization which the Etruscans possessed long before Rome was heard of, is testified by innumerable works of masonry and art. The Etruscans were of an eminently practical turn of mind, and domestic, like the north. Trusting to their priests for reconciliation with the gods, who always seemed irate, but whose angry decrees could easily be foreseen and averted, they set to work in developing the inner resources of the country, and in making the best use of their intercourse with foreign countries. They thus became eminent in agriculture, navigation, military tactics, medicine, astronomy, and the like; and in all these, as well as in some of the very minutiae of their dress and furniture, the Romans became their ready disciples and imitators. The division of the year into 12 months, of the months into kalends and nones and ides, the designation of the numerals, were Etruscan; from the same source were derived the *toga pretexta* as well as the pomp of triumphs, the *lictors* and *apparitors*, down to the ivory curule chairs. The towns of the Etruscans were clean and healthy, owing to their perfect system of drainage and sewerage; they tunneled and excavated, they embanked and irrigated, they turned swamps into cities, changed the course of streams, and excelled in all kinds of useful public and private works. Their ideal was not the beautiful or the spiritual, but a comfortable, and, if possible, luxurious existence. As a special proof of their love for their own hearth, a quality probably imported from the north, we might adduce their invention of the atrium, the common sitting-room of the family, where the master of the house sat surrounded by his penates and the figures of his ancestors, while the wife and her handmaidens plied the labors of the loom or the distaff. As in the Germanic nations, woman stood in high estimation. She was the companion, not the slave of the husband, and thus had certainly not a little share in the softening of their primitive wildness, and in counteracting the somberness of their creed. That we find them even in their tomb-paintings engaged in convivial carousings, dancing, races, athletic games, and that they liked their very worship accompanied by the sound of flutes, horns, and trumpets, only shows that that glorious sky of theirs, their intercourse with the nations, their wealth and culture, had gradually caused their antique and gloomy austerity to wear off, even as it wore off with the Romans and other peoples; for to assume with some that the boisterous scenes to which we allude were caused more or less by the despair arising from the loss of their independence, would be going somewhat too far. Licentiousness is the sure forerunner of the fall of a nation, but a whole people does not take refuge in enjoyment when their all is lost. We know little of Etruscan literature; it seems to have consisted mostly of rituals, religious hymns, and some historical works. Whether the Fescennines, certain mocking-songs, sung in alternate verses, with musical accompaniment, at nuptials, originated with them or not, is not decided.

We have alluded to the high proficiency of this people in architecture; they were, in fact, so renowned in this craft throughout the antique world, that, as Solomon called Phenicians to Jerusalem to build his temple, so the Romans sought in Etruria the framers of their grandest masonic structures, such as the Cloaca Maxima, the temple of Jupiter on the capitol, etc. The peculiarly fantastic, and, withal, powerful mind which speaks in all their institutions, equally pervades their architectural productions; but, at the same time, everything they built, they built either for practical or pious purposes. We cannot here enter into a discussion of their manner as it appears in various epochs, but it never reached anything like a distinct national completeness, their eagerness to profit by foreign examples not allowing them to develop it to the full unalloyed. Of their walls and gates, temples and porticoes, theaters and amphitheaters, bridges and sewers, gigantic, and, in the earliest times, cyclopean—evidently erected, in eastern fashion, by hosts of slaves—very little is extant in so complete a form as to give us an exact insight into their mode of construction; and were it not for their tombs, our knowledge would be exceedingly limited. These form one of the most peculiar features in Etruscan antiquities. Hewn in rocks, either below the ground or in the face of a cliff, they were adorned outside with a somewhat Egyptian façade of a temple or a house, which the insides themselves most exactly reproduce, with all their internal decorations, furniture, and utensils. Of the paintings which run round the walls, and which are our safest and most complete guides to the inner life of this nation, we will say more presently. We must not, in conclusion, omit to mention that their temples bore in primitive times, and always retained, in some measure, so far as we can judge, the unfinished character of the wood-buildings of northern mountain tribes—a square, half-house, half-fortification, overloaded with quaint ornamentation.

In their plastic and pictorial arts, Winckelmann has established three distinct styles—to which Dennis has added a fourth—viz., the Egyptian, with Babylonian analogies, the Etruscan or Tyrrhene proper, the Hellenic, and that of the *decadence*. Characteristic of the first style are the prevalence of straight lines, right angles, faces of an oblong, contracted oval, with a pointed chin, eyes mostly drawn upwards, the arms hanging close to the side, the legs close together, the drapery long, in straight parallel lines, the hair disposed in tiers of curls. In this style, the attitude is constrained, the action stiff and cramped. The progress shown by the second style is the greater attention bestowed on the delineation of the muscles, which swell out in disproportionate prominences on the

now almost entirely nude body. The two remaining styles explain themselves. Their statuary, as it appears chiefly on sarcophagi and cinerary urns, suggests likewise an Egyptian origin. The figures are those of their own mystical and awful Hades, instead of the Bacchic processions of Greece and Rome. The grouping follows rather a pictorial than a plastic principle; the motion is hasty and forced; but the features of the deceased, hewn on the lid, have all the rude accuracy of a spiritless portrait. Statues of deities in wood and stone have indeed been found, but very rarely. Of high renown were their ornaments and utensils in baked clay (*terra cotta*), in the manufacture of which objects the Veientes were especially famous. Rome, at a very early period, possessed of this material a quadriga and the statue of Summanus, made by Etruscans. Of the art of working in bronze, the Etruscans were supposed to be the inventors: that they brought it to a very high degree of perfection, is evident from the examples which remain to us. Statues and utensils were manufactured and exported in immense quantities, not only to Rome, but to every part of the known world. Of figures on a large scale still extant, we may mention the renowned she-wolf of the capitol, the chimera in the museum of Florence, the warrior of Todi in the Etruscan museum of the Vatican; a portrait-statue of an orator, with the inscription *Aule Meteli*, in Florence; and the boy with the goose at Leyden. The various objects of ornament and use, found in great numbers in tombs, such as candelabra, cups, tripods, caldrons, couches, disks; articles of armor, as helmets, cuirasses, etc.; musical instruments, fans, cists, or caskets, are most of them models of exquisite finish and artistic skill. Their gems are as numerous as those of Egypt, and like them, cut into the form of the *scarabæus* or beetle. They were exclusively intaglios, and of cornelian, sardonyx, and agate. On these the Etruscan artists represent groups from the Greek mythology, or the heroic cycle, bereft, as they seem to have been, of heroic legends of their own. They are most frequently found at Chiusi and Vulci, and were worn as charms and amulets. Special mention should be made of the metal *specula*, or mirrors, with figures scratched upon the concave side, the front or convex side being highly polished. These ranged over all the phases of Etruscan art, and are especially and peculiarly Etruscan. None but Etruscan inscriptions have ever been found upon them. They will, no doubt, prove eventually of the highest importance, not only by enabling us to follow the gradations of artistic development step by step, but by furnishing us with lists of names of gods and persons, and, it may be, of objects.

Of the vases and urns which are found in innumerable quantities in Etruscan tombs, we cannot treat here, as they are admitted on all hands to be, with very few exceptions, Greek, both in design and workmanship; we must refer the reader to the special article on VASES, but a few words may be added on the before-mentioned tomb-paintings. They are found chiefly in the cemeteries of Tarquinii and Clusium; and they are all the more important, as they lead us with minute accuracy from the very cradle of the individual, through the various scenes of his entire life, to its close; and this throughout the existence of the nation itself, beginning before the foundation of Rome, and ending in the empire; while we follow the style in its gradual development from the Egyptian to Græco-Roman perfection. Life in its merriest aspects gleams in the most vivid of colors all round—dancing, feasting, loving, hunting. The Etruscans of later times had learned in the school of the Hellenes to dread death less, and to think of the other world as one of continued joyfulness.

The Etruscan language is preserved in more than 3,000 inscriptions, and this number will no doubt be doubled by the opening of new sepulchral chambers, with which the soil of ancient Etruria is teeming. These inscriptions are found on sarcophagi, urns, vases, columns, statues, and looking-glasses in bronze. The latter article was a favorite object for the representation of scenes from Greek mythology, and from this source we learn the names of the principal native deities. *Tinia*, was Jupiter; *Usil*, the sun; *Fufuns*, Bacchus; *Sethlans*, Vulcanus; *Thurms*, Mercurius; *Turan*, Venus; *Thalna*, Juno; *Thesan*, Aurora. Some of the minor female deities are called *Lasa*, *Maris*, *Mean*, *Vanth*. The inscriptions are of two kinds—the archaic and more recent. The former, generally beginning with the syllable *MI*, are distinguished not merely by a more ancient form of the alphabet, but also by a more refined condition of the language. In the older inscriptions consonants and vowels are evenly balanced. But in the documents of a later date, short vowels are generally omitted, and in consequence, combinations of consonants appear which remind us strongly of the cacophonous forms of some of the Slavonic languages. Compare the following specimens: 1. *Mi Tesantiaia Tarchumenaia*. 2. *Laris Sesctna Lumsclal*.

With regard to the grammar, the following points may be considered as established. In the singular of nouns, the nominative ends in *s*; the genitive, according to the class of declension, in *a-s*, *e-s*, *i-s*, *u-s*; the dative in *si* or *s*. But these terminations are very often dropped, just as in early Latin. In the Cippus Perusinus, both the largest and best preserved inscription of all now in existence, we find of the proper names *Velthina* and *Afuna* the cases: *Velthina*, *Velthinam*, *Velthinas*; *Afuna*, *Afunam*, *Afunas*. The suffix *al* serves mostly, but not exclusively, for the expression of a metronymic. *Thana Seianti Latinial*, for example, is *Thana Seiantia*, the daughter of *Latinia*. Another very common suffix—*asa*, *esa*, *isa*, *usa*—designates the matrimonial relation of women. *Thana Aulnei Canznasa* is *Thana Aulnea*, the wife of *Canzna*; *Tha Setumnei Pumpunisa*

is Thana Setumneia, the *wife* of Pomponius. It is clear that this suffix consists of the genitives in *as, es, is, us*, with the addition of an *a*, so that grammatically and logically the wife is defined as part and parcel of her husband. Verbal forms do not occur often, but it is certain that the preterite is formed from the root by the addition of the syllable *ce*, like *tur-ce, the-ce, lupi-ce, sval-ce*. The numerals sound rather strange. *Mach, thu, zal, huth, ki, sa*, are 1 to 6; but as yet the individual meaning of each of these is unknown. The same must be said of *sesphs, esal, mu* or *muw*, the numerals for 7 to 9. Decades are expressed by *alch(a)*, e.g., *sespalchal, muwalchl, cealchl*. Ninety was probably *zathurms*. The meaning of about 10 or 12 words, such as *clan*, son; *sech*, wife; *avil*, age; *vril*, year; *hinthial*, spirit; *fleses*, statue, can be clearly established; but as yet no affinity has been discovered between these and the corresponding expressions in languages, whether Arian or otherwise. The following two inscriptions are given with a translation which in one or two points is conjectural:

Vipia Alsinai turce Versenas Caia.
Vibia Alsinæa dedit Versenæ, Caiæ filiæ.

The second is found on the celebrated bronze statue of the orator, now preserved in the museum of Florence:

Aulesi Metelis Ve Vestial clensi cen fleses tece
Aulo Metello Velie Vesie filio hoc signum posuit
sansl tenine tuthines chisulics.
jussu concilii publici magistratus (?)

The few bilingual inscriptions (altogether 15) throw no light on the language, as they contain only proper names. The so-called Tyrrhenian glosses, preserved in the lexicon of Hesychius, are worse than useless for critical purposes. See Dennis, *Cities and Cemeteries of Etruria* (1878); Isaac Taylor, *Etruscan Researches* (1885); Corssen, *Die Sprache der Etrusker* (1878). For illus. of architecture, etc., see *ENGINEERING*, vol. V.; *ARCHÆOLOGY*, vol. I.

ETRURIA, KINGDOM OF. A kingdom established in Italy by Napoleon I. in 1801, formed out of the province of Tuscany, and assigned by him to the Bourbons. In 1809, its status was changed so that it became a duchy, and part of the French empire. Napoleon's sister, Elise Bonaparte, wife of Col. Bacciocchi, was made Duchess of Etruria and Lucca and Princess of Piombino. On the overthrow of Napoleon in 1814 it reverted once more to the Austrian Grand-duke Ferdinand III., as the grand-duchy of Tuscany.

ETSCH. See *ADIGÉ*.

ETTLINGEN, the chief t. of the circle of Carlsruhe, Germany, on the railway between Manheim and Basel, $4\frac{1}{2}$ m. from Carlsruhe; pop. abt. 6000. It has manufactures of paper, cotton, starch, powder, etc. There is an old castle built on the site of a Roman fortress. Ettlingen was conquered in 1644 by Taupadel; and near the town, in 1796, Moreau was defeated by the archduke Charles. Roman antiquities are found in the neighborhood.

ETTMÜLLER, ERNST MORITZ LUDWIG, an able writer on German antiquities, was b. 5th Oct., 1802, at Gersdorf, in Upper Lusatia, and studied medicine at Leipsic from 1823 to 1826, but subsequently the language and history of his native country. In 1830, having taken his degree of *PH.D.* at Jena, he began to deliver lectures there on the German poets of the middle ages; in 1833, he was called to the Zürich academy, and in 1863, to the university there, as professor of German literature. E.'s literary activity found development chiefly in the editing of the literary remains of the Middle High-German, and older Low-German dialects. To the former belong his *Sant Oswaltes Leben* (Zürich, 1835); *Hadeloubes Lieder und Sprüche* (Zürich, 1840); *Heinrich's Von Meissen des Frowenlobes Lieder, Leiche, und Sprüche* (Quedlinb. 1845); *Frowen Helchen Süne* (Zürich, 1846); *Heinrich's Von Veldecke Eneide* (Zürich, 1852). Of poems composed in Low German he published, among others, *Theophilus* (Quedlinb. 1849); and *Wizlives IV., des Fürsten Von Rügen, Lieder und Sprüche* (Quedlinb. 1852). In 1850 appeared, under his editorship, an Anglo-Saxon chrestomathy; in the following year his much-valued *Lexicon Anglo-Saxonicum*. E. also gave his attention to the old Norse literature, as is shown by an edition of the *Völuspá*, translations, and a Norse reading-book. E. H. Müller also wrote several original poems: his *Deutsche Stammkönige* appeared at Zürich in 1844; his *Kaiser Karl d. Gr. und das Fränkische Jungfrauenheer* in 1847; and his *Karl d. Gr. und der Heilige Goar* in 1852. *Herbstabende und Sommernächte* are essays on his favorite subjects (3 vols., 1865-67). He d. 1877.

ETTRICK, a pastoral vale in the s. of Selkirkshire, watered by the Ettrick river, which rises amid bleak hills in the s.w. corner of this co. near Ettrick Pen, 2,258 ft. high, and runs 28 m. n.e., and falls into the Tweed. Its chief affluent is the Yarrow, which runs 25 m. from the w., through one of the loveliest of Scotch vales, and the scene of many a plaintive song. Ettrick forest, a royal hunting tract, swarming with deer till the time of James V., included Selkirkshire and some tracts to the north. In Ettrick Vale, at Tushielaw, dwelt the celebrated freebooter or king of the border, Adam Scot, who was summarily executed by James V. The district derives some note from two persons in modern times—Thomas Boston (q.v.), a Scottish divine, who was minister of the parish of E.; and James Hogg, the Scottish poet, who, having been originally a shepherd in this part of the country, became known as "the Ettrick shepherd."

"ET TU, BRUTE!" (Lat., "And thou also, Brutus!") The words are commonly believed to have been uttered by Julius Cæsar, when struck by the hand of Brutus. There is, however, absolutely no authority for attributing these words to Cæsar. The strong popular belief in their authenticity is a remarkable tribute to the genius of Shakespeare, who puts them into Cæsar's mouth at the moment of his fall. But Shakespeare did not originate them. They seem to have occurred for the first time in an old Latin play on the subject of Julius Cæsar, written by Dr. Eades, the master of Christ Church college, Oxford, in 1582, and acted in that year by the undergraduates. They next appear in the *Mirror for Magistrates*, in the narrative called *Cæsar's Legend*, and published in 1587. Again, they are found in a poem by one S. Nicholson, called *Acolastus his Afterwit*, which appeared in 1600. In his poem the lines run :

"Et tu, Brute ? Wilt thou stab Cæsar, too ?
Thou art my friend, and will not see me wronged."

Shakespeare probably found the words in *The True Tragedie of Richard, Duke of York* (1600), from which he drew "The Third Part of King Henry VI." In it is the line :

"Et tu, Brute ? Wilt thou stab Cæsar, too ?"

As Malone says, Shakespeare rejected the line in writing the play just mentioned, but it seems to have lingered in his memory and reappeared in the *Julius Cæsar* whence it passed into the stock of quotations that are the property of all mankind.

ETTY, WILLIAM, R.A. This distinguished artist was b. at York, Mar. 10, 1787. His father was a miller and spice-maker. Before he was 12 years of age, he was apprenticed to a printer, and served out his dreary term of seven years, the irksome drudgery of which he himself often afterwards was in the habit of narrating, occasionally soothed by dreams of, on some future day, being an artist. Freed at last, and assisted by some relatives, in 1805, at the age of 18, he entered on the study of art, and, after a year's probation, was admitted as a royal academy student. His career is very interesting and instructive. It exhibits one gifted with enthusiasm for art, high resolutions, and great industry and perseverance, for a series of years invariably surpassed by many of his fellow-students, and, as has been recorded, "looked on by his companions as a worthy plodding person, with no chance of ever becoming a good painter." Neither prizes nor medals fell to his share as a student; and for several years his pictures were rejected at the royal academy and British institution exhibitions. It was only after six years of hard study that he obtained a place for a picture in the exhibition of the royal academy; and his works only began to attract notice in 1820, when the artist was 33 years of age, and as he himself has said, "having exhibited nine years to no purpose." But the circumstance of E.'s genius being so long unappreciated, did not so much arise from his works evincing no talent, as from his class of subjects, and those technical qualities for which his works are remarkable, not being appreciated at the time; for long before his pictures were salable, his powers were highly appreciated by his professional brethren. On his return from Italy in 1822, where he had been studying the great Venetian colorists, he was elected an associate of the academy. In 1824, his *chef-d'œuvre*, "The Combat—Woman pleading for the Vanquished," was purchased by an artist, John Martin. In 1828, he was elected academician by the members of the royal academy; while in the same year the royal Scottish academy testified its high appreciation of his talents by purchasing the most important of his efforts, the historical work illustrating the history of Judith and Holofernes. Testimonials so high soon had their effect; E.'s pictures came into great request, and brought large prices, and he was enabled amply to repay those who, trusting to his energies, had assisted him when he entered on the contest, in which, after so arduous a struggle, he gained so much honor. He always cherished a love and reverence for York, his native city, and had retired there some time previous to his death, which took place on Nov. 30, 1849.

ETYMOLOGICUM MAGNUM, a Greek lexicon of unknown authorship, said to be the oldest extant in that language. It is thought to have been made in the 10th century.

ETYMOLOGY (Gr.) is that part of grammar that treats of the derivation of words. It embraces the consideration of the elements of words, or letters and syllables, the different kinds of words, their forms, and the notions they convey; and lastly, the modes of their formation by derivation and composition. Etymological inquiries have formed a favorite pursuit from the earliest times. In the book of Genesis, numerous indications are given of the derivation of proper names. Homer also attempts etymologies of the names of gods and men, which, however, can only be looked upon as more or less ingenious fancies. The grammarians of Alexandria and Varro among the Romans tried to base their etymologies on something like principle; but the wildest conjectures continued to be indulged in, and the results were little better than guess-work down to a very recent period. As philology extended its sphere, and became acquainted with the languages and grammarians of the east, who far excelled those of the west in this particular, etymology took on a new form. It no longer sought the relations of the words of a single language exclusively within itself, but extended its view to a whole group, e.g., the Teutonic, or wider still, to a whole family, as the Indo-European, or Aryan (q v.), and became a new science under the name of comparative grammar. See GRAMMAR; PHILOLOGY.

ETYMOLOGY, FIGURES OF, are deviations from the ordinary forms of words. *Apharesis* (Gk. a taking away) consists in taking away one or more letters from the *beginning* of a word, as 'neath for *beneath*, 'tis for *stis*, 'st for *est*. *Apocope* (Gk. a cutting away) consists in taking away a letter or letters from the *end* of a word, as *th'* for *the*, *tho'* for *though*, *tun'* for *tune*. *Diæresis* (Gk. a separating) is the separation of one vowel sound into two, as *Orphëus* (three syllables), instead of the usual *Orphëus* (of two syllables). This figure occurs chiefly in verse. See **PROSODY, FIGURES OF**. *Epenthesis* is the insertion of one or more letters in a word, as *alittum* for *alitum*, *Alcumena* for *Alemena*, *techina* for *techna*. *Metaplasm* is a general term used to denote any alteration made in the letters or syllables of a word. Such alteration may take place in three ways: first, by addition, which may be at the beginning (by *prosthesis*), in the middle (*epeuthesis*), or at the end (*paragoge*); second, by taking away from the beginning (*apharesis*), from the middle (*syncope*), or from the end (*apocope*), or by contracting the vowels (*synæresis*); third, by the transposition of letters (*metathesis*). *Metathesis* (Gk. a transposing) is the transposition of two letters, as *cretus* for *certus*, *pistris* for *pristis*, *centre* for *center*, and in the numerous other words whose final syllable exhibits this double form of *re* and *er*. *Paragoge* is the addition of one or more letters at the end of a word, as *withouten* for *without*, *vasty* for *vast*. So *dicier* was said to have been formed by paragoge from *dicti* by the addition of *er*. *Prosthesis* is the addition of a letter or letters at the *beginning* of a word, as *adown* for *down*, *bedecked* for *decked*. So, in the Greek *onoma* (Lat. *nomen*), the *o* is thought to be prosthetic. *Synæresis* (Gk. a taking together) consists in condensing two syllables into one, as *walk'st* for *walkest*, and in the numerous cases where a final *ed* is combined in pronunciation with the preceding syllable, as *hallowed*. *Synæresis* is the opposite of diæresis, and is identical with *synecphonesis* and *synizesis*. See **PROSODY, FIGURES OF**. *Syncope* (Gk. a striking together) is the omission of a letter from the middle of a word, as *fortnight* for *fourteen-nights*, *e'en* for *even*, *ne'er* for *never*, *ev'ry* for *every*.

EU, a tolerably well-built t. of France, in the department of the Lower Seine, in Normandy, situated near the mouth of the Bresle, 93 m. n.n.w. of Paris. It is remarkable for its fine Gothic church, and for the château d'Eu, a low building of red brick, with high tent-shaped roofs of slate. E. manufactures sail-cloth, ropes, soap, lace, and silk. Pop. '91, 4693. In the 11th and 12th centuries, E. was in the possession of the counts of the same name, a collateral branch of the Norman royal family. After various vicissitudes, it was purchased by Mademoiselle de Montpensier in 1675, whose fanciful taste has perpetuated itself in the architecture and decoration of the château. At a later period, it came into the possession of the duke of Maine, from whom it passed to the duke of Penthievre, the maternal grandfather of Louis Philippe, who succeeded to it in 1821. Louis Philippe expended large sums on the embellishment of the château, and especially on its magnificent park and the unique portrait-gallery. It has besides acquired a new historical association through the visits of the queen of England in 1843 and 1845. The eldest son of the duke of Nemours (born 29th April, 1842) received from his royal grandfather the title of Count d'Eu. Compare Vatout, *Le Château d'Eu, Notices Historiques* (5 vols., Paris, 1836), his *Résidences Royales* (Paris, 1839).

EU, Prince LOUIS PHILIPPE MARIE FERDINAND GASTON D'ORLEANS, Comte d', b. France, 1842, eldest son of duke de Nemours and grandson of Louis Philippe. In 1864, he was married to Isabel, heiress-apparent of the throne of Brazil. He was a marshal in the Brazilian army, and was commander-in-chief of the allied forces in the war with Paraguay in 1869. He defeated Lopez, and proclaimed the abolition of slavery in Paraguay. His unpopularity with the army was a powerful cause of the proclamation of the republic in 1889, after which he lived in France.

EUBŒA (ancient, *Euboia*; Turkish, *Egripo*; Ital. *Negroponte*), the largest island in the Ægean sea, forms a portion of the present kingdom of Greece. Until recently, it was called Negropont. It is bounded on the n. by the Trikeri channel, and on the w. by those of Talanta and Egripo. It extends in a direction parallel to the mainland; is 105 English statute m. long, and 30 m. in extreme breadth, although in one part its breadth is scarcely 4 miles. At the narrowest part, it is connected with the mainland by a bridge. The island is intersected by a chain of mountains, running n.w. and s.e., and attaining in the centre in the range of Mt. Delphi, an elevation of about 4,500 feet. Copper and other metals are obtained in the island, which also contains numerous hot springs. The pastures are excellent and the declivities of the mountains covered with forests of fir-trees. The climate is salubrious, the valleys well watered and very fertile, but little cultivated. The chief products are cotton, oil, wine, wheat, fruit, and honey. The inhabitants are chiefly engaged in the breeding of cattle; they export wool, hides, and cheese, as well as oil and grain. The chief towns are Chalcis (q.v.) on the n., and Carystos on the s. coast. The land on each side of the Egripo channel suffered from an earthquake in 1894. E. was peopled in the early historic times chiefly by Ionic Greeks, and afterwards by colonists from Athens, who formed a number of independent cities or states. These were at first monarchical in their constitution, but at a later period democratic. They soon rose to power and prosperity. After the Persian wars, however, E. was subjugated by the Athenians, under whose rule it continued till they,

in their turn, were subdued by Philip of Macedon. By the Romans it was finally united with the province of Achaia under Vespasian. In 1204 it came into the possession of the Venetians, and received the name of Negroponte. In the year 1470 the island was taken by the Turks, in whose hands it remained till 1821, when the inhabitants rose to vindicate their independence at the call of the beautiful Modena Maurogenia. It now forms with the Sporades a province of modern Greece.

EUCALYPTUS, a genus of trees of the natural order *myrtaceæ*, suborder *leptospermeæ*, containing a large number of species, mostly natives of Australia, and which, along with trees of nearly allied genera, form one of the most characteristic features of the vegetation of that part of the world. The genus occurs also, although much more sparingly, in the Malayan archipelago. The trees of this genus have entire and leathery leaves, in which a notable quantity of a volatile aromatic oil is usually present. The leaves, instead of having one of their surfaces towards the sky, and the other towards the earth, are often placed with their edges in these directions, so that each side is equally exposed to the light. Many of the species abound in resinous secretions, and are therefore called **GUM TREES** in Australia. Some of them attain a great size.

BOTANY BAY KINO, a secretion which is used in medicine as a substitute for kino (q.v.), is the produce of *E. resinifera*, a species with ovato-lanceolate leaves, known in Australia as the **RED GUM TREE** and **IRON BARK TREE**, a very lofty tree, attaining a height of 150–200 ft. When the bark is wounded, a red juice flows very freely, and hardens in the air into masses of irregular form, inodorous, transparent, almost black when large, but of a beautiful ruby red in small and thin fragments. Botany bay kino is said to consist chiefly of a peculiar principle called *eucalyptin*, analogous to tannin. About sixty gallons of juice may sometimes be obtained from a single tree, or, in the course of a year, as much as five hundred pounds of kino.—*E. robusta*, **STRINGY BARK TREE**, also a lofty tree, yields a most beautiful red gum, which is found filling large cavities in its stem, between the concentric circles of wood.—*E. mannifera* yields, from its leaves, an exudation resembling manna, less nauseous, and of similar medicinal properties. It contains a saccharine substance, different from *mannite*, from *glucose*, and from all previously known kinds of sugar. Another similar exudation, from the leaves of *E. dumosa*, is sometimes seen spread over large districts like snow, and used by the natives as food.—The Tasmanian blue gum tree, which is one of the eucalypti, has recently acquired great reputation for its effects in drying marshy soils, and in preventing malarious diseases. It is extremely rapid in its growth, which may account for its drying powers; and this, in its turn, may partly account for its salubrious effects; although its camphor-like odor may also have to do with it. It has been tried with decidedly beneficial effects in the cape of Good Hope, Algeria, the Roman Campagna, and California.

EUCHARIST. See **LORD'S SUPPER**.

EUCHLORINE is a very explosive green-colored gas, possessing bleaching properties, and is prepared by heating gently a mixture of 2 parts hydrochloric acid, 2 of water, and 1 of chlorate of potash. It explodes when merely touched with a hot wire, and is most likely composed of a mixture of chlorine and chlorochloric acid (2ClO_5 , ClO_5).

EUCHRE, a game of cards said to be of German origin, but now very popular as a social pastime in the United States. Thirty-two cards are used in E., the twos, threes, fours, fives, and sixes being rejected in a complete pack. Before the game is started the players cut for deal, which belongs to him who first draws a knave or the lowest card according to agreement. The non-dealer then cuts to his opponent, who deals five cards to each, by two at a time and three at a time or vice versa. The dealer turns up the top of the undealt cards for trumps. In suits not trumps the cards rank as at whist; in the trump suit the knave (termed the right bower) is the highest trump, and the other knave of the same color, either black or red (termed the left bower) is the next highest, this card being, of course, omitted from the suit to which it would otherwise belong. The other trumps rank as already stated, the queen being next above the ten. The best form of the game is when played by four persons, but two, three, or even more than four persons may play, if the rules be adapted accordingly. In two-handed euchre the non-dealer looks at his hand and decides whether he will play it. If he be satisfied and think he can make three tricks, he "orders up." The dealer then discards his lowest and least useful card, and is entitled to take the trump card into his hand; in this case, however, he must succeed in taking three tricks, or he is "euchred," and his opponent scores two points. If the non-dealer be not satisfied with his hand, he says "pass." The dealer then has the option of taking up the trump as before, or of passing also. If the trump be ordered up or taken up, the play of the hand commences; if both players pass, the dealer places the trump card face upwards underneath the pack, called "turning it down." The non-dealer has then the privilege of naming the suit which shall be trumps, which must be another than that previously turned up. If he "make" a trump, he must succeed in taking three tricks or he is euchred; but if he pass it again, the dealer has the option of making it. If both pass a second time, the hand is thrown up, and the other player deals. When the card turned up is red and

the trump is made red, it is called "making it next;" the same with black. If the trump be made of a different color from the turn up, it is called "crossing the suit." If the hand be played, the non-dealer leads; the dealer plays to the card led. He must follow suit if able, otherwise he may play any card he pleases. If the left bower is led, a trump must be played to it. The highest card of the suit led wins the trick; trumps win other suits. The winner of the trick leads to the next. If a player make all five tricks he scores a "march," equal to two points; if he make three or four tricks he scores one point. In three-handed euchre the option of playing or passing goes to each in rotation, beginning with the player to the dealer's left. Three cards, one from each hand, constitute a trick. The player who orders up, takes up, or makes the trump, plays against the other two, and if they succeed in euchring him, each of them scores two points. This is often termed "cut-throat euchre," because any one of the three players is liable to be opposed by the other two. Four-handed euchre is generally played with partners, who are cut for, and sit opposite each other as at whist; if a player have a strong hand he can decide to "play alone" single-handed against the two adversaries, and his partner cannot object. Should the lone player succeed in making a march he scores four; if he win three or four tricks he scores one; if he fail to win three tricks the opponents score two. The popularity of euchre in this country is due mainly to its simplicity and mirth-provoking qualities. It is played in many different ways, as the game is not bound by any strict set of rules. Sometimes a blank card called "little joker" or "the joker" is added, and is the highest card in the pack, the bowers following; sometimes it is agreed upon to allow the player who makes more than five points to carry the surplus (called a lap) to the next game; or to allow a "lone player" to call for his partner's best card.

EUCLASE, a silicate of alumina and glucina occurring in greenish crystals; it is hard, and will bear a high polish, but is fragile and not much used in jewelry. It is found in South America.

EUCLID, of Megara, a Greek philosopher, has often been confounded with the mathematician of the same name. He was one of the earliest disciples of Socrates. Although Megara lay at a considerable distance from Athens, and all Megarians were forbidden to enter the Athenian territories under pain of death, E. came into the city in the evening in female disguise, to enjoy the instruction of Socrates. After the death of his master, he established a school of his own, which received the name of the Megaric school. His death took place about 424 B.C. The basis of his system was in the Eleatic dogma of a one, only, universal substance or existence. Blending with this the Socratic idea of the predominance of the moral element, E. held this one real existence to be *the good*, though it receives various names under its special manifestations.

EUCLID, sometimes called the father of mathematics, was b. at Alexandria, about 300 B.C. We know little more of his history than that he belonged to the Platonic school of philosophy, and taught mathematics in the famous school of Alexandria, during the reign of Ptolemy Soter. Though he did not create the science of mathematics, as is sometimes represented, he made prodigious advances, especially by his rigorous method and arrangement. In this respect he has perhaps never been excelled, and his *Elements of Geometry* continue to the present day to hold their place as a text-book of that science. Besides the Elements, there are extant treatises on music, optics, data, etc., ascribed to E., the authenticity of some of which is doubtful. The best editions of the whole reputed works of E. are those of David Gregory (Oxf. 1703) and Peyrard (3 vols., Par. 1814-18). The oldest Greek edition of the Elements appeared at Basel, 1533; the best is that of August (2 vols., Berlin, 1826). Of English editions of E.'s Elements, those of Simpson and Playfair are considered the best. There is a full account of everything connected with E. and his works in Smith's *Dictionary of Greek and Roman Biography*; and in Ball's *History of Mathematics* (1888).

EUDIOMETER (Gr. *eudios*, good, and *metron*, measurer) is an instrument originally introduced as a measurer of the goodness of air in any locality, but which is now employed generally in the analysis of gases for the determination of the nature and proportions of the constituents of any gaseous mixture. The instrument is now made of glass in the form of a tube, which is hermetically sealed at one end, and open at the other. The tube may be straight, or bent in the shape of the letter U. In either case, the tube is graduated or marked off in equalized divisions from the closed end onwards, so as to admit of the volume of gas placed within being accurately measured; and two platinum wires are inserted through the glass near the shut end of the tube, and closely approach, but do not touch, each other. These wires are intended for the conveyance of electric sparks through any mixture of gases, so as to cause the combustion of certain of them. For the modes of manipulating with the eudiometer, see **GAS ANALYSIS** OF.

EUDO'CIA, the name of several Byzantine princesses, of whom the most important is the wife of the emperor Theodosius II. She was b. about 393, the daughter of the sophist Leontius, or Leon, and was educated by her father, who instructed her in the literature of Greece and Rome, in rhetoric, geometry, arithmetic, and astronomy. Her accomplishments and her singular beauty were reckoned by Leontius a sufficient fortune, for at his death

he left all his property to her two brothers. E. appealed to the emperor at Constantinople. Pulcheria, the sister of Theodosius, was interested in the maiden, and thought she would make a suitable wife for the emperor. But as E. (or, more properly, Athenais, for this was her name until her baptism) had been brought up a pagan, it was necessary first to convert her. This was easily accomplished. E. was married to the emperor in 421 A.D. For many years, however, Pulcheria ruled in the imperial household and councils, E., according to Nicephorus, "submitting to her as mother and Augusta;" but in 447, a quarrel broke out between them in regard to the Eutychian heresy, of which E. had become a supporter. At first, E. was triumphant, and Pulcheria was banished; but in a short time the emperor was reconciled to his sister, and treated E. so sharply that she retired to Jerusalem, where she died 460-61 A.D. Her latter days were spent in works of piety and charity. She enriched churches, rebuilt the walls of the holy city, and founded many monasteries and hospitals. Through the influence of the famous Symeon Stylites, she was induced to renounce Eutychianism, and become an orthodox Catholic Christian. E. was a poetess of considerable merit. She wrote a poem in heroic verse on the victory obtained by the troops of Theodosius over the Persians, 421 or 422 A.D.; a paraphrase of eight books of Scripture, a paraphrase of Daniel and Zechariah; and a poem in three books on the history and martyrdom of Cyprian and Justina. The authorship of *Homero-Centones* has also (but without sufficient reason) been attributed to her. This is a work composed of verses taken from Homer, and so arranged as to appear a history of the fall of man and of his redemption by Christ. It has been often published.

EUDOX US, of Cnidus, called by Cicero the prince of astronomers, flourished about 366 B.C. He studied under Plato for some time, and afterwards went to Egypt, where he resided for thirteen years, and had much intercourse with the Egyptian priesthood, from whom he is supposed to have derived his superior knowledge. His last years are said to have been spent on the summit of a high hill, that he might have the starry heavens ever before his eyes. There is little reason for believing that E. deserves any great admiration for his attainments in astronomy. He probably introduced the sphere into Greece, and may have corrected the length of the year, upon Egyptian information, but he appears to have been an indifferent observer of heavenly phenomena, and Delambre considers that he was ignorant of geometry. E.'s works are entirely lost, and our only reliable sources of information regarding him are the poem of Aratus and the commentary of Hipparchus.

EUFAULA, a city in Barbour co., Ala., on the Chattahoochee river, at the head of navigation, and on the Central of Georgia railroad; 80 m. e. s. e. of Montgomery. It is an important cotton manufacturing and shipping point; has gas and electric lights, water works owned by the city and completed in 1897 at a cost of \$60,000; Bluff park, city and railroad bridges over the river, Union female college and conservatory of music, several churches, national banks, and daily and weekly newspapers. Pop. '90, 4394.

EUGÈNE, FRANÇOIS (le prince François-Eugène de Savoie-Carignan), better known as Prince Eugene, distinguished as a general and as a statesman, was b. at Paris, 18th Oct., 1663. He was the son of Eugene Maurice, count of Soissons, and of Olympia Mancini, a niece of Cardinal Mazarin. He was intended for the church; but the banishment of his mother to the Low Countries, by the orders of Louis XIV., was so deeply resented by him, that he indignantly renounced his country, and entered the service of the emperor Leopold as a volunteer against the Turks. Subsequently, the French government made him the most flattering offers, but he never returned to the service of his native country. He displayed extraordinary military talent in the Turkish war, especially at the famous siege of Vienna in 1683, and soon rose to a high position in the army. In the coalition war against Louis XIV. in Italy, he took an active part; and in 1691, was raised to the command of the imperial army in Piedmont. On his return to Vienna, he was placed at the head of the army of Hungary, and defeated the Turks, with immense slaughter, in the famous battle of Zenta, Sept. 11, 1697. The booty obtained was almost incredible, amounting to several millions sterling. In 1701, broke out the Spanish war of succession. E. for two years commanded the army of Italy, but his forces were too small for him to accomplish anything of importance. In the year 1703, being appointed president of the council of war, he became thenceforth the prime mover of every undertaking. He first took the command of the imperial army in Germany, and along with Marlborough gained a brilliant victory at the battle of Blenheim, 13th Aug., 1704, when the two commanders defeated the French and Bavarian army. E. afterwards saved Turin, and expelled the French from Italy in the year 1706. He shared, too, with Marlborough the glory of the fields of Oudenarde (in 1708) and Malplaquet (in 1709); but being crippled in his resources by the retirement of Holland and England from the contest, he was unable to withstand the enemy on the Rhine, and his defeat by Villars at Danain, 24th July, 1712, was followed by other disasters, until the peace of Rastadt put an end to the war. In 1716, on the commencement of the war against the Turks, E. defeated an army of 180,000 men at Peterwardein, took Temeswar, and in the year 1717, after a bloody battle, gained possession of Belgrade. After the peace of Passarowicz, which was concluded in the following year, he returned covered with glory to Vienna, where, during the succeeding years of peace, he labored with unwearied energy in the cabinet. When the question of the succession to the throne of Poland brought on a new war with France, E. appeared

again on the Rhine; but being now advanced in years, and destitute of sufficient resources, he was unable to accomplish anything of importance. After the peace, he returned to Vienna, where he died, 21st April, 1736. E. was small in stature, with thin face, and long nose; he was simple in dress and manner, and indulged profusely in snuff. An enthusiast in his profession, and a strict disciplinarian, he was also kind-hearted and sympathetic, and always carefully attended to the wants of his men. He introduced no new tactics in the art of war, and was deficient in the guidance and command of masses; but by his rapidity of perception and decision, and faculty for making the best of existing circumstances, which was his *forte*, he raised the *prestige* of the Austrian arms to an eminence unequalled before or since his time. He successively served under three emperors, of whom he was wont to say, that in Leopold I. he had a father, in Joseph I. a brother, and in Charles VI. a master. E.'s political writings, published by Sartori, are important for the light they throw upon the history and manners of the time. Compare Dumont, *Histoire Militaire du Prince Eugene*; Ferrari, *De Rebus Gestis Eugenii* (Rome, 1747); Campbell's *Military History of Prince Eugene and the Duke of Marlborough*; and the monographs of Kausler (1838), Arneth (1858), Von Sybel (1861), and Pulitzer (1895).

EUGENIA, a genus of plants of the natural order *myrtaceæ*, nearly allied to *myrtus* (see MYRTLE), and differing only in having a 4-parted instead of a 5-cleft calyx, four instead of five petals, and a 1 to 2-celled berry, with one seed in each cell.

EUGÉNIE-MARIE DE GUZMAN, formerly empress of the French, was b. at Granada in Spain, 5th May, 1826, and is the second daughter of the count of Montijo and of Marie Manuela Kirkpatrick. She is descended, on the father's side, from an old and noble Spanish family, which, by marriages at various times, acquired the right to assume the names of Guzman, Fernandez, Cordova, La Cerda, and Levía, and contracted alliances with the noble families of Téba, Banos, and Mora. By her mother—also born in Spain, and the daughter of Mr. Kirkpatrick, who was for some time English consul at the Spanish seaport of Malaga—she is connected with an ancient Scottish family—the Kirkpatricks of Closeburn—which still exists, but no longer in possession of their original property. She was educated principally at Madrid, and spent a great portion of her youth in traveling with her mother, under the name of the countess of Téba. In 1851, she appeared at the *fêtes d'Elysée* in Paris, where her beauty and graceful demeanor attracted the notice and excited the admiration of the emperor of the French, who married her on the 30th Jan., 1853, at Notre Dame. On that occasion an amnesty was granted to 4,312 political prisoners. In 1859 the empress filled with ability the office of regent. During the war in 1870 she was again regent, but had to flee to England after the emperor became a captive, and afterward passed the greater part of her time at Camden House, Chislehurst, England. Her only son, the prince imperial, born 16th Mar., 1856, completed his military education in England, and was killed in 1879 while serving as a volunteer in the Zulu war. See De Lano, *The Empress Eugénie* (1894), and Comte d'Hérisson, *The Prince Imperial, Napoleon IV.* (1894).

EUGENIUS is the name of four popes, of whom the last is the most important. E. IV., a native of Venice, became pope in 1431. The great event in his career was the schism created in the church by the proceedings of the council of Basel, which had been convoked by E.'s predecessor, Martin V., and showed a strong tendency to ecclesiastical reform. E. was kept in perpetual trouble by this council, and at last, having been compelled to flee from Rome, opened a new council at Ferrara in 1438, and issued a bull of excommunication against the bishops assembled at Basel, whom he pronounced to be "a satanic conclave, which was spreading the abomination of desolation into the bosom of the church." The result was, that the council of Basel formally deposed him from his pontifical office in 1439, and elected in his stead Amadeus VIII., duke of Savoy, under the title of Felix V. The conduct of France and Germany seemed to warrant this bold step, for Charles VII. had introduced into the former country the decrees of the council of Basel, with some modifications, through the pragmatic sanction (1438), and the same thing happened in Germany by means of the deed of acceptance (1439). At the council of Ferrara, John Paleologus II., emperor of Constantinople, and upwards of 20 Greek bishops, presented themselves, and a union between the two great divisions of Christendom—the Greek and Latin church—was for a moment effected in July, 1439. Discord, however, broke out almost immediately, and the two have ever since remained separate. E.'s rival, Felix, did not obtain much recognition, and after the death of the former at Rome, in 1447, he had to give way in favor of Nicholas V.

EUGUBINE TABLES (Lat. *Tabulæ Eugubineæ*), the name given to seven bronze tablets, the inscriptions on which present a comprehensive and very remarkable memorial of the Umbrian language. They were discovered in 1444 at Gubbio (the ancient Iguvium or Eugubium), where they are still preserved. The characters on four of the tablets are Umbrian, on two Latin, and on one partly Latin and partly Umbrian. The language employed, however, is in all cases the same, and differs both from Etruscan and Latin, but resembles somewhat the older forms of the latter, and also the Oscan dialects, so far as we know them. The subjects of the inscriptions are directions concerning sacrificial usages and forms of prayer, and they seem to have been inscribed three or four centuries before the Christian era. Philip Buonarrotti first published them in a complete form in Dempster's *Etruria Regalis* (2 vols., Florence, 1723-24). The first really judicious attempt at interpretation was that of Lanzi, in his *Saggio di Lingua Etrusca* (3

vols., Rome, 1789), who points out the important fact that they related to sacrificial usages, etc. His views have been carried out by Ottfried Müller in his work *Die Etrusker*; Lepsius, *De Tabulis Eugebinis*, etc. The most accurate copy of the inscriptions is that given by Lepsius in his *Inscriptiones Umbrice et Osce* (Leip. 1841); the best and most complete work on the language and contents of the tablets is that of Aufrecht and Kirchhoff, entitled *Die Umbrischen Sprach und Denkmäler* (2 vols., Berlin, 1849-51.)

EUHEMERISM, the name usually applied to the historical theory of the origin of mythology advanced by Euhemerus, a native of Messene, and a contemporary of Cassander of Macedonia, in the fourth century B.C. According to this view, myths are history in disguise. All the gods were once men, whose real feats have been decorated and distorted by later fancy. In the course of a voyage to the Indian sea, Euhemerus professed to have discovered an island called Pauchia, in which he found inscriptions representing the principal gods of Greece as mere earth-born kings and heroes, deified after death for their superior strength or wisdom. His book, *Hiera Anagraphê*, as well as a Latin translation of it by Ennius, is lost. It drew upon him the charge of atheism, and its unblushing inventions made his name a by-word for mendacity. Its main theory, however, was adopted by many eminent men, including Polybius, as well as by some of the Christian writers—by Minucius Felix, Lactantius, and St. Augustine—who found the ground ready prepared for them in their effort to strip the pagan gods of the attributes of deity. Later Greek writers carried the theory still further, eliminating everything supernatural, and leaving only a string of tales perfectly credible and commonplace. Æolus became an ancient mariner with a special knowledge of the winds, Atlas a great astronomer, and Scylla a fast-sailing pirate. Euhemerism was a favorite theory of the philosophical historians of France in the eighteenth century, and the translation of Abbé Banier's work, *The Mythology and Fables of Antiquity explained from History*, extended it to England. To this school belong also writers such as Vossius, Bochart, and Huet, who find traces of sacred as well as profane history in Greek mythology. Thus, Saturn is identified with Noah, and his sons, Zeus, Poseidon, and Hades, with Shem, Ham, and Japhet. The latest and ablest exponent of sacred euhemerism is Mr. Gladstone, who sees in Zeus, Poseidon, and Hades, the dimmed figures of the Christian Trinity; in Apollo, the Jewish Messiah; and, in his mother Latona, the woman whose seed should bruise the serpent's head. Herbert Spencer is also an euhemerist in his explanation of the origin of religion. He bases all the religious emotions on primitive ancestor-worship, and explains totemism, a condition everywhere present in the savage world, as due originally to mere human nicknames, which were gradually forgotten, and afterwards came to have a sense of mystery connected with them. See ANCESTORS, WORSHIP OF.

EULENSPIEGEL is the hero of a *Volksbuch*, or German popular comic tale, often alluded to by various old authors, entitled the *Story of Tyl Ulenspiegel*, which relates the freaks, pranks, drolleries, fortunes, and misfortunes of a wandering mechanic. "It were long to detail his fearful jokes, which sometimes brought him to the gallows, yet saved him from the halter. He was buried with his coffin standing on one end at Möllen, near Lübeck; and you may see his grave under the great lime-tree in the churchyard, and his rebus, to wit, an owl and a looking-glass, cut upon the stone." Ulenspiegel, as he is sometimes called in German, has almost made the tour of Europe. His life was first published in the Nether-Saxon dialect, in 1483. Our English translation of *The merry jests of a man that was called Hecleglass, and of many marvellous things and jests that he did in his life in Eastland*, was "Imprinted at London in Tamestreete, at the Vintre, in Three Craned Warfe, by Wyllyam Copeland."

A High-German version, the work of Thomas Murner, the Franciscan monk, was printed at Strasburg in 1519. A Latin translation was made by Nemius, and numerous French translations have appeared of the book. An English edition was published in 1860, under the direction of Kenneth R. H. Mackenzie, and with illustrations by Alfred Crowquill. There is no complete copy of the original, but portions in the royal library at Vienna and the royal library at Berlin complement each other. See OWLGLASS.

EULER, LEONARD, one of the greatest of mathematicians, was b. at Basel, April 15, 1707, and received his first instructions in the science, for which he afterwards did so much, from his father, who was pastor of the neighboring village of Riehen. At the university of Basel, he studied under John Bernouilli, and was the friend of Daniel and Nicholas Bernouilli. At the age of 19, he was second in the contest for a prize offered by the academy of Paris for the best treatise on the masting of ships. His friends, the Bernouillis, had been called to St. Petersburg by Catharine I., when she founded the academy, and they now induced E. to settle in that capital, in 1730, as professor of physics. Three years later he exchanged his professorship for a place in the academy. From that time he continued to labor in the field of mathematics with an ardor really astonishing. More than half the mathematical treatises in the 46 quarto volumes published by the St. Petersburg academy from 1727-83 are by E., and at his death he left more than 200 treatises in MS., which were afterwards published by the academy. The Paris academy of science awarded him the prize on ten several occasions, one of which was his treatise on Tides, 1740. In 1741, he accepted the invitation of Frederick the Great to Berlin. He afterwards, 1766, returned to St. Petersburg,

where he was made director of the mathematical department of the academy, and died Sept. 7, 1783. The last years of his life were spent in total blindness.

E. was of an amiable and religious character, always cheerful and good-humored; in society, he was distinguished for his agreeable wit. It was doubtless his residence in St. Petersburg that led him to the application of mathematics to the building and management of ships, as embodied in his *Théorie de la Construction et de la Manœuvre des Vaisseaux* (Petersb. 1773). The great problems left by Newton to his successors were the objects of his unceasing research. On physical subjects, E. often adopted extremely untenable hypotheses. He occupied himself also with philosophy in the proper sense of the word. He undertook to prove the immateriality of the soul, and to defend revelation against freethinkers. In his *Lettres à une Princesse d'Allemagne sur quelques Sujets de Physique et de Philosophie* (3 vols., Berl. 1768; new ed., Par. 1812; and which have also been translated into English), he attacked Leibnitz's system of monads and of a pre-established harmony. But this was not the field in which he was best calculated to shine; his proper domain was the abstruser parts of pure mathematics. His most important works of this class are his *Theory of Planetary Motion*; *Introduction to the Analysis of Infinites*; *Institutions of the Differential and of the Integral Calculus*; and *Dioptrics*; which are all, as well as his *Opuscula Analytica*, in Latin. His *Introduction to Algebra* is well known.

EUMENES, 360–316 B.C.; a native of the Thracian Chersonesus; private secretary to Philip of Macedon, and also to his son Alexander the Great, under whom he was a commander of the cavalry. After Alexander's death, the provinces and armies were divided among his generals, and the countries assigned to Eumenes were Cappadocia and Paphlagonia, with the sea-coast of Pontus as far as Trapezus; but as they were not yet subdued, Leonnatus and Antigonus were charged by Perdiccas to put Eumenes in possession. Antigonus disregarded the order, and Leonnatus, having in vain endeavored to induce Eumenes to accompany him to the assistance of Antipater in Europe, made an unsuccessful attack on Eumenes's life. But Eumenes escaped and joined Perdiccas, who assisted him in getting possession of Cappadocia. He did not rule long, having the enmity of many powerful generals. He was betrayed by his own soldiers, and put to death.

EUME'NIDÉS (literally, the well-minded or benign goddesses) was the euphemistic name of certain fearful beings, whose true name of Erinnyes (from *erino*, I hunt up, or *eruno*, I am angry) it was considered unlawful to utter. Their Latin name was *furie* or *diræ*. We find them mentioned by the earliest poets, and they play a prominent part in the writings of the tragedians, where their sphere of action is much extended. In the earliest times, Homer and Hesiod represent them as avenging and punishing perjury and murder, as also the violation of filial duty and of the rite of hospitality; they were also regarded as goddesses of fate (like the *Parcæ*) and had a share in the grim providence which led the doomed ones into the way of calamity. A part of their function was also to hinder man from acquiring too much knowledge of the future. In these poets, their number is sometimes undefined; sometimes they appear as one. The limitation to the number three, as well as their names Alecto, Megæra, and Tisiphone, is of a later period, a whole chorus of Erinnyes appearing in the writings of Æschylus. According to Homer, they dwell in Erebus, and with this the duration after death of the punishments which they inflict is connected. Hesiod calls them the daughters of Ge and Uranus. Æschylus describes them as having the features of gorgons and harpies, their bodies covered with black, serpents twined in their hair, and blood dripping from their eyes. The later poets and sculptors represented them in the more pleasing form of winged virgins, attired in the garb of huntresses, bearing torches in their hands, and with a wreath of serpents round their heads. Gradually, they came to be considered goddesses of the infernal regions, who punished crimes after death, but seldom appeared on earth. In Athens, their worship, which, like that of the other infernal deities, was conducted in silence, was held in great honor. The sacrifices offered to them were black sheep and libations of *nephalia*—i.e., honey mixed with water. The turtle-dove and the narcissus were sacred to them. They had a sanctuary in the vicinity of the Areopagus, and one at Colonus.

EUMOLPUS (the "sweet singer") was, in the later mythology of Greece, the son of Poseidon and Chione. He was brought up in Ethiopia, whence he went to Thrace, and afterwards passed into Attica, at the head of a body of Thracians, to assist the Eleusinians in their war against Erechtheus, king of Athens. E. and his sons are said to have been slain in battle. He is spoken of as the founder of the Eleusinian mysteries. A distinction is made by some of the ancient writers between this E. and a son of Musæus bearing the same name. The latter is represented as a scholar of Orpheus, and the instructor of Hercules; but E.'s history, like all mythological stories, is involved in great obscurity and confusion. The name of E. is one of the series of those old priestly singers who, by the institution of religious ceremonies, spread culture and morality among the rude inhabitants of Hellas. An illustrious Athenian family, the *Eumolpidae*, derived their descent from E., and held the office of priests of Demeter in Eleusis.

EUNATIUS, b. 347 A.D. ; a Greek sophist, and enemy of Christianity. He possessed some knowledge of medicine, and was a teacher of rhetoric at Athens. He wrote *Lives of the Sophists*, and a continuation of the history of Dexippus.

EUNOMIUS, the founder of the Arian sect of Eunomians, was b. in the village of Dacora, in Cappadocia, and was first a lawyer, then a soldier, and ultimately took holy orders. In 360, he was appointed bishop of Cyzicum. In the great controversy regarding the nature of the Trinity which raged during the 4th c., E. was conspicuous by his advocacy of the view that the Father alone was eternal and supreme; that the Son was generated of Him; and the Holy Spirit, again, of the Son. His doctrine of the Trinity is sometimes called the *anomoian* ("dissimilar"), to distinguish it, on the one hand, from the *homoiousian* ("similar"), held by the semi-Arians, and, on the other, from the *homoousian* ("identical"), held by the Athanasian or Trinitarian party. It was thus the extreme of Arianism. In defense of his peculiar views, E. is said to have shown superior ability, although his opponents also accuse him of being verbose and inflated in his style. His life was much checkered. He was banished from one place to another, until at length he obtained permission to retire to his native village, where he died in 394. His writings have entirely perished, with the exception of a fragment here and there preserved in the writings of his adversaries.

EUNOMIUS, b. Cappadocia, early in the 4th c. ; leader of a sect of Arians who took his name. He was bishop of Cyzicus in 360, but was afterwards deposed for heresy by the bishop of Antioch. His writings were held in high esteem by his followers, and were so much dreaded by the orthodox that more than one imperial edict was issued for their destruction. His heresy was formally condemned by the council of Constantinople.

EUNUCH. The original signification of this word (Gr. *eunuchos*, one who has charge of a bed) points to the office that this class of persons fulfilled, and still fulfill in the east—that, namely, of taking charge of the women's apartments or harems. The barbarous practice of employing castrated males as guardians of the other sex, is an accompaniment of polygamy, and is therefore chiefly met with in the east and in n. Africa. If it has appeared in countries where monogamy was the law, it was in consequence of the introduction of oriental luxury, as was the case under the Roman emperors. The practice is of great antiquity, and seems to have originated in Libya, and from that to have spread to Egypt and the east. Syria and Asia Minor were the most notorious in this respect. In Greece, it never obtained any great footing; for although Greek women were kept in seclusion, polygamy itself never prevailed. The later Romans kept eunuchs, but they were mostly imported. In the Byzantine empire, on the contrary, castration and keeping of eunuchs were very prevalent. This class played a prominent part in the court of the eastern empire, and the word E. came to be the title of an office similar to that of chamberlain. In modern times, the practice is mostly confined to Mohammedan countries, and the eunuchs are chiefly brought as slaves from the interior of Africa. See CASTRATION.

EUOMPHALUS, a large genus of fossil gasteropodous shells, characterized by its depressed and discoidal shell, with angled or coronated whorls, five-sided mouth, and very large umbilicus. The operculum was shelly, round, and multi-spiral. The genus seems related to *trochus*. It appears among the earliest tenants of the globe, and keeps its place till the triassic period. No less than eighty species have been described.

EUONYMUS. See SPINDLE TREE.

EUPATORIA (formerly *Koslov*), a thriving maritime t. of Russia, in the government of Taurida, is situated on a bay in the w. coast of the Crimea, 15 m. n.w. of Old Fort, and 38 m. n.w. of Simferopol. The town stands on the border of a monotonous pastoral steppe, and is surrounded by low hills. Seen from the sea, it presents, with its occasional minarets and its houses roofed with red tiles, a somewhat picturesque appearance. The principal building is the Tartar mosque, built by Devlet-Ghiri Khan in 1552, and reckoned the finest in the Crimea. E. exports corn, wool, and salt. Its harbor is shallow, and is sheltered only from the n. and n.e. winds. Pop. abt. 17,350, mostly Crim-Tartars and Jews, who are engaged chiefly as farmers and shepherds, and possess an immense number of oxen and sheep, and a large area of badly cultivated land.

On the 14th Sept., 1854, a portion of the Anglo-French invading army landed here, and occupied and fortified the town. It was also the scene of a battle between the Russians and Turks, 17th Feb., 1855, in which the latter were victorious.

EUPATORIUM, a genus of plants of the natural order *composite*, sub-order *corymbifera*, having small flowers (heads of flowers) in corymbs, florets all tubular and hermaphrodite, club-shaped stigmas, imbricated bracts, a naked receptacle, and a hairy pappus. The species are numerous, and mostly American. One only is British, the common HEMP AGRIMONY (*E. cannabinum*), a slightly aromatic perennial plant, growing mostly in marshy places, and on the banks of streams. The root was formerly employed as a purgative, and the plant was also used as a diuretic and as a vulnerary. —THOROUGH-WORT (*E. perfoliatum*), a species having the opposite leaves joined at the base, is very common in low grounds in North America, and is a popular medicine,

much esteemed and used in this country. It is often administered in intermittent fevers. It acts powerfully as a sudorific, and is often very beneficial in catarrh and influenza. It is also emetic and purgative, and, in small doses, tonic. The whole plant is very bitter.—Other North American species possess similar properties, and the root of one, known as GRAVEL-ROOT (*E. purpureum*), is employed as a diuretic for relief of the disease from which it derives its name.—The AYAPANA (*E. ayapana*), a half-shrubby species, native of the n. of Brazil, has a high reputation in that country as a cure for snake-bites, and has been introduced into the East Indies. It is a very powerful sudorific, and is also diuretic.—The famous Peruvian vulnerary, MATICO, has been referred, but uncertainly, to a shrubby species of this genus, *E. glutinosum*.—GUACO or HUACO, much valued in Peru as a cure for snake-bites, is supposed to belong to the allied genus *mikania*.

EUPEN, a flourishing manufacturing t. of Rhenish Prussia, is situated in a beautiful valley on the Weeze, within 2 m. of the Belgian frontier, and 9 m. s.s.w. of Aix-la-Chapelle. It is well built and open, including within its limits several gardens and meadows. E. is known for its extensive woollen manufactures, and has a variety of other industries. It owes the prosperity of its manufactures chiefly to a number of French refugees, who settled here after the peace of Lunéville. It was a part of the Duchy of Limburg till the treaty of Lunéville (1801), by which it was ceded by Austria to France; but it was gained from the latter power by Prussia in 1815. Pop. '90, 15,445.

EUPHEMISM (Gr. *eu*, well, and *phemi*, I speak) is a figure of rhetoric by which an unpleasant or offensive matter is designated in indirect and milder terms. Thus, instead of directly calling up an unpleasant image by the word *died*, we say, "he was gathered to his fathers." The ancients used a multitude of euphemisms, to avoid words that were thought to be ominous of evil, or offensive to the unseen powers. They spoke, for example, of the Eumenides, or "benign goddesses," instead of the Furies; just as the elves and fairies of modern superstition are spoken of as "good neighbors."

EUPHON, or **EUPHONON**, a musical instrument invented by Chladni in 1790. It is similar in tone to the harmonica, and, like it, the tone is produced from the sounding body by the finger direct, without mechanism, and is regulated in quality and effect by the taste and feelings of the performer, who can produce tones from the most delicate pianissimo to fortissimo. In 1822, Chladni exhibited an improved E. of which a detailed description is given by himself in the Leipzig *Musik-zeitung* of that year, p. 805.

EUPHORBIA, OIL OF, or OIL OF CAPER SPURGE, an extremely acrid fixed oil, obtained by expression, or by the aid of alcohol or ether, from the seeds of the caper spurge (*euphorbia lathyris*), a plant common in many parts of Europe, and naturalized in some places in America. See SPURGE. Oil of euphorbia has much resemblance to croton oil in its properties, although less powerful, and is sometimes used as a substitute for it, in doses of from three to ten drops. It is good for use only when recently extracted.

EUPHORBIA CEE, a very extensive natural order of exogenous plants, containing upwards of 2,500 known species—trees, shrubs, and herbaceous plants. They abound chiefly in warm countries, and most of all in tropical America. The few species found in the colder parts of the world are all herbaceous. The common box reaches a more northern limit than any other shrubby species. The other British species are different kinds of spurge (*euphorbia*) and dog's mercury (*mercurialis*). The E. usually abound in an acrid and poisonous milky juice; although there are species of which the juice is bland or becomes bland through the application of heat, so that their leaves may be used as food. The leaves in this order exhibit great diversities. The inflorescence is also various. Amongst those most remarkable for the acidity of their juice are the MANCHINEEL (q.v.) and *cacæaria agallocha*, an East Indian tree—formerly supposed to yield one of the kinds of aloes-wood—the smoke from the burning of which is extremely dangerous to the eyes. The juice of many of the spurges is also very acrid. Many of the E. are valued for their medicinal properties, different parts of the plant being in some instances employed, and in some the resins and oils which they yield. Thus the juice of some of the spurges, the roots or bark of the roots of others, the bark of different species of *croton* (cascarilla bark, copalche bark), etc., are used in medicine; and to plants of this order we are indebted for euphorbium, oil of euphorbia, castor oil, croton oil, etc. A few of the E. yield balsamic products of exquisite fragrance (see CROTON); a few, although their juice is poisonous, yield a wholesome starch in considerable abundance (see MANIOC); a few are cultivated and used as pot-herbs, particularly species of *plukenetia* in the East Indies; a few yield wholesome and agreeable sub-acid fruits, as *cicca disticha* and *C. racemosa* in the East Indies; the seeds of some are eatable, as those of the candle-nut (q.v.), of *omphalea diandra*, a Jamaica tree, and of *conceveiba Guianensis*, the latter being esteemed particularly delicious; the oil of the seeds is also in some cases used for food, like other bland oils (see CANDLE-NUT); but more frequently it is used for burning, as castor oil, candle-nut oil, the oil of *elaeococca verrucosa* in Japan and Mauritius, and the concrete oil of *stillingia sebifera*, which is used in China for making candles, and in medical preparations as a substitute for lard.

—The dye-stuff called Turnsole (q.v.) is obtained from a plant of this order; and a bright red is imparted to silk by the roots of *rottlera tinctoria*, a native of Circassia, and by a red powder with which its seed-vessels are covered. The timber of some of the E. is valuable. African teak (q.v.) belongs to this order. The red-colored wood of *stylo discus trifolius* is used in Java for making masts. Some of the E. are often cultivated in gardens and hot-houses, more frequently for their curious appearance than for their beauty; but the large deep crimson bracts of *poinsettia pulcherrima*, a native of Madagascar, make it a very attractive plant.

EUPHORBIA, an extremely acrid gum resin, obtained from several species of *euphorbia* or Spurge (q.v.), as *E. officinarum* and *E. antiquorum*, in the n. of Africa, Arabia, and the East Indies, and *E. canariensis* in the Canary islands. It is obtained by incisions in the branches, whence issues a corrosive milky juice, which dries in the sun, and becomes a yellowish-gray waxy gum resin. The persons who collect it are obliged to defend their mouths and nostrils by a cloth, as its particles produce incessant sneezing, violent inflammation of the nostrils, and a very painful burning sensation in the mouth. On account of its excessive acridity, it is now less used in medicine than formerly; although it is still occasionally mixed with burgundy pitch or other substances to make rubefacient plasters for chronic affections of the joints; its alcoholic tincture is used as a caustic in carious ulcers, and its powder, mixed with much starch or flour, as an *errhine* in chronic affections of the eyes, ears, or brain. It was formerly administered as an emetic and drastic purgative, but is dangerously violent in its action.

EUPHRANOR, a sculptor and painter of Greece in the 4th c. B.C. One of his finest works in sculpture was a figure of Paris, a copy of which is in the Vatican. His chief painting was extant at the time of Pausanias. It represented on one wall of a temple the twelve gods, and on the other wall Theseus as the founder of the equal polity of Athens.

EUPHRASIA. See EYEBRIGHT.

EUPHRATES (in the oriental languages, *Frat*, *Phrat*, or *Forat*) is the largest river in western Asia, and, with the Tigris, forms the most important river-system of that quarter of the world. It has its source in the heart of Armenia in two branches—the Kara Su and the Murad, of which the former rises 25 m. n.e. of the town of Erzerum, and flows s.w. to a point 10 m. n. of Keban' Ma'den, where it is met by the Murad, which rises on the southern slope of Alá Tagh, and flows w.s.w. to the point of confluence. From Keban' Ma'den, the E. flows in a general southern direction, with a tendency, however, to struggle westward towards the Mediterranean. In this part of its course, it breaks through the Taurus, and flows among the mountains for 45 m., emerging at Sumeisat, whence it continues navigable to the sea—a distance of 1195 m.—and passing Bir, at which point it is 628 ft. above the level of the Mediterranean, and 100 m. distant from its nearest shore. After passing Samosta, it changes its direction, and flowing s., separates for a considerable distance Mesopotamia from Syria and the deserts of Syrian Arabia. Curving to the s.e., it flows on without receiving almost any tributaries for about 700 m., until it is joined at Kurnah or Kornah by the waters of the Tigris. From Kurnah, the river, taking the name of the Shatt-el-Arab, continues to flow in a s.e. direction, until, after being united by a canal with the Karun from the mountains of Persia, it empties itself, by several arms, into the Persian gulf, 90 m. below Kurnah. The total length of the E. is 1600 m.; the area drained by all the waters which enter it is estimated at 260,000 square miles; and the volume of water discharged by it is 401,010 cubic ft. per second, or 72,910 cubic ft. more than that discharged by the Danube in the same time. The average width of the Shatt-el-Arab is upwards of 600 ft.; it is navigable in mid-stream for vessels of 500 tons. The water of the E., although muddy, is not unwholesome. Its inundations, caused by the melting of the snows, take place chiefly from the beginning of Mar. till the end of May; and in ancient times, when canals and embankments regulated these inundations, exercised the same beneficial effect on the country as those of the Nile on Egypt. See Peters, *Nippur or Explorations and Adventures on the Euphrates* (1897); also the article BABYLON.

EUPHROSINE (i.e., the joyous one), one of the Graces (q.v.).

EUPHUISM (Gr. *euphuos*, of vigorous growth; eloquent), a term used in English literature to denote an affected and bombastic style of language, fashionable for a short period at the court of Queen Elizabeth. The word was formed from the title of the book which brought the style into vogue, the *Euphuos* of John Lyly (q.v.).

EUPIONE (Gr. *eu*, good, and *pion*, oil) is an extremely mobile oil, obtained from the lighter portions of the liquid products of the destructive distillation of wood (wood-tar), coal (coal-tar), and animal matter, and in the distillation of rape-seed oil. It may be obtained in a sufficient state of purity by acting upon the crude tars and oils by concentrated sulphuric acid, or a mixture of sulphuric acid and niter, which removes the majority of the other ingredients; and on the distillation of the portion which resisted the action of the acid, the first part which passes over is the eupione. When pure, it has the composition C_8H_8 , and is therefore a hydro-carbon. It is the lightest liquid known, having the density of 655 (water = 1000), and is thin, colorless, and tasteless, while it possesses a pleasant aromatic odor. It boils at 116° F., and distills readily;

whilst, when set fire to, it is very inflammable, burning with a white flame of considerable luminosity and penetrating power. It makes a greasy stain on paper, is insoluble in water, very slightly soluble in alcohol, but readily miscible with ethers and oils in general.

EUPODA, a family of coleopterous insects of the tetramerous section of the order, deriving their name (Gr. well-footed) from the great size of the hinder thighs of many of the species. They feed on the stems and leaves of plants, some of them on aquatic plants, the roots of which afford food to their larvæ. The body is oblong; the antennæ filiform. Some of the E. are among the most splendid of tropical insects. Britain produces a number of small species.

EUPOLIS, b. 445 B.C.; an Athenian poet of the old comedy, ranking, in the opinion of Horace, with Cratinus and Aristophanes. It is said that he was thrown into the sea by Alcibiades, who had suffered from his sarcasm; but, according to another account, he fell in either the battle at Cynossema, 411 B.C., or that of Ægospotami, 408 B.C. He was sufficiently great to have a quarrel with Aristophanes on mutual charges of plagiarism.

EURA'SIAN, from Eur (Europe) and Asia; a half-breed, offspring of an Asiatic mother and European or American father. This class is very numerous in the large cities of India, and at the ports open to foreign commerce in Burmah, Siam, China, and Japan. In person they are usually handsome, well-formed, and, as a rule, learn the language of their fathers; but are not well esteemed by either natives or foreigners. By the laws of Japan and of Great Britain, the sons are citizens with their fathers, the daughters with their mothers.

EURE, a river of the n.w. of France, and a tributary of the Seine, rises in the department of Orne, flows first s.e. into the center of the department of Eure-et-Loir, then n. and n.w. through the departments of Eure-et-Loir and Eure, and joins the Seine on the left above Pont-de-l'Arche, after a course of about 100 miles. Only that portion of the E. which is in the department of Eure is navigable.

EURE, a department in the n.w. of France, immediately s. of the department of Seine Inférieure, contains an area of 2,300 sq. miles. Pop. 340,652. Its surface is unusually level, as the highest eminences in the department are not more than 300 ft. in height. The principal river is the Seine, which, entering the department from the s.e., flows through it in a n.w. direction to Pont-de-l'Arche, below which the course of this river is in the department of Seine Inférieure. The Eure, from which this department derives its name, and the Rille, both affluents to the Seine, are the only other important rivers. The chief natural products are grain (especially wheat and oats), hemp, flax, vegetables, and fruit, particularly apples and pears, from which large quantities of cider and perry are made. The breeding of cattle, horses, and sheep, is favored by extensive meadow and pasture-lands. There are extensive iron and copper works and pin manufactories. Cotton goods, cloth, linen, paper, glass, and stoneware are likewise manufactured. The department of Eure is divided into five arrondissements—Évreux, Louviers, Les Andelys, Bernay, and Pont-Audemer. The capital is Évreux (q. v.).

EURE-ET-LOIR, a department of France, formed chiefly from the province of Orléanais, extends between lat. 47° 57' and 48° 55' n., and long. 0° 47' and 2° east. Area, 2,263 sq. miles. Pop. '96, 280,469. It is watered mainly by the Eure in the n., and the Loir in the s., the two rivers from which it takes its name. This department lies on the watershed between the bay of Biscay and the English channel. It is in general level, the e. and s. being occupied by high and extensive flats; while in the w. the scenery is finely varied by hill and valley. The soil is fertile.

EUREKA (Gr.). "I have found it." An exclamation attributed to Archimedes, the famous philosopher of Syracuse. Hiero the king sent a quantity of gold to a jeweler to be made into a crown. He suspected that the man had taken some of the gold and supplied its place with alloy. Therefore he asked Archimedes to test the work and determine the truth. The philosopher was just then stepping into his bath, and as he did so the water overflowed. The fact struck his mind that the water was displaced in ratio with the bulk of the object immersed, and suggested to his mind that, as a pound of gold was much smaller than a pound of silver, the trial of the crown in water would be a sure test. Convinced of the fact, he jumped from the bath, shouting "Heureka! Heureka!" and, without waiting to dress, ran home to prove the truth of his discovery.

EUREKA, a co. in e. Nevada, formed 1873. Area, 4150 sq. m.; pop. '91, 3275. Co. seat, Eureka.

EUREKA, city and co. seat of Humboldt co., Cal.; on Humboldt bay and the Eel river and Eureka railroad; 225 miles n. of San Francisco. It has an excellent harbor, which has been improved by the U. S. government on the jetty plan; is supplied with gas and electric lights, streets paved with bitumen, sidewalks of concrete and redwood planks, and waterworks; and is principally engaged in the shipment of redwood lumber and dairy products. Sequoia park is a tract of 20 acres of virgin redwood forest near the city, kept unimproved excepting by drives and trails. Pop. '90, 4,858.

EUREKA, a town and co. seat of Eureka co., Nev., in the Diamond mountains; 65 m. e. of Austin. It is the centre of a cluster of very rich mines of silver and lead; is almost wholly engaged in mining, smelting, and refining silver; has several churches, a bank,

and a weekly newspaper; and is connected with Palisade station, on the Central Pacific railroad, by the Eureka and Palisade railroad. Pop. '90, 1609.

EURIPIDES, the latest of the three great Greek tragedians, was b. at Salamis, 480 B.C., on the very day (23d Sept.), it is said, of the glorious victory gained by the Greeks over the Persians near that island. The Arundel Marble, however, gives as the date of his birth 485 B.C., while Müller, following Eratosthenes, makes it four years later. His education was very good. At first, he was trained to gymnastic exercises (in consequence of the prediction of an oracle that he should be crowned with "sacred garlands"); he next turned his attention to painting; then studied philosophy under Anaxagoras, and rhetoric under Prodicus, and formed a lasting friendship with Socrates. The first play of E.'s which was performed was the *Peliades* (456 B.C.). In 441 B.C., he gained the first prize for tragedy, and continued to write for the Athenian stage until 408 B.C., when he accepted an invitation to the court of Archelaus, king of Macedonia. Scandal has invented other reasons for E.'s leaving Athens, but they are unworthy of notice. He is said to have been killed (406 B.C.) by dogs, which were set upon him by two brother-poets who envied him his reputation. In E.'s time, Greek tragedy had been brought to its highest perfection by Sophocles, who was 15 years older than Euripides. The latter, however, was the second favorite author of his time; nay, on more than one occasion, his tragedies were preferred to those of Sophocles; but his liberal and even neologistic tendencies in regard to religion, excited the hostility of that witty but scurrilous champion of Greek orthodoxy, Aristophanes, who frequently ridiculed E. in cutting parodies. There can be no doubt that E. was systematically abused by the Athenian tory party, of whom Aristophanes was the literary chief, and to whose unscrupulous opposition it was owing that he gained the prize only five times out of 75 competitions. But against the censure of Aristophanes may be set the praise of two much greater men—Aristotle and John Milton. E.'s plays are reckoned by some to have amounted to 75, by others to 92. Only 18 have come down to us. These are *Alceste* (438 B.C.), *Medea* (431 B.C.), *Hippolytus* (428 B.C.), *Heccuba* (424 B.C.), *Heracleida* (421 B.C. ?), *Supplices* (421 B.C. ?), *Ion* (date not ascertainable), *Hercules Furens* (date not ascertainable), *Andromache* (420–17 B.C.), *Troades* (415 B.C.), *Electra* (415–13 B.C.), *Helena* (412 B.C.), *Iphigenia in Tauris* (date uncertain), *Orestes* (408 B.C.), *Phænissa* (probably same year), *Bacchæ* (probably written in Macedonia), *Iphigenia in Aulis* (posthumously represented in Athens); and finally, *Cyclops* (uncertain). *Rhesus*, attributed to E., is probably not genuine. Concerning E. and his tragedies, A. W. Schlegel remarks: "Of few authors can so much good and evil be predicated with equal truth. He was a man of infinite talent, skilled in the most varied intellectual arts; but although abounding in brilliant and amiable qualities, he wanted the sublime earnestness and artistic skill which we admire in Æschylus and Sophocles. He aspires only to please, no matter by what means. For this reason, he is so frequently unequal to himself; producing at times passages of exquisite beauty, and frequently sinking into positive vulgarity." The main object of E. was to excite emotion, and his works laid open a totally new world (in literature), that of the heart, which, beyond dispute, contributed much to their popularity. On the other hand, his inartistic and careless plots compelling him to a constant use of the *deus ex machina* solution of difficulties, and occasionally even the subjects of his art themselves, leave ample room for criticism. Archelaus refused to allow his bones to be removed to Athens, and erected a splendid monument to him in Pella, with the inscription: "Never, O Euripides, will thy memory be forgotten!" Still more honorable was the inscription on the cenotaph erected to him by the Athenians on the way to the Piræus: "All Greece is the monument of Euripides; Macedonian earth covers but his bones." Sophocles, who survived him, publicly lamented his loss; and the orator Lycurgus afterwards erected a statue to him in the theater at Athens. The *editio princeps* of E. appeared, it is thought, at Florence, toward the end of the 15th century. The best modern editions are those of Beck (Leip. 1778–88), Matthiæ (Leip. 1813–29), Kirchhoff (1867), and Nauck (1885). In 1892, Mr. Flinders Petrie discovered in Egypt papyri containing part of a lost play of Euripides, the *Antiope*. See Verrall, *Euripides the Rationalist* (1895).

EURIPUS, the channel between the island of Eubœa and the coast of Greece. Opposite Chalcis it is but a little over 60 yards wide and 7 or 8 ft. deep. There is a rock in the channel, on which stands a castle connected with both shores by bridges. This double bridge is said to have been built originally as early as the 4th c. B.C.

EUROCLYDON, the name given to a wind which caught the ship in which Paul undertook his voyage to Rome. Biblical scholars are not entirely agreed as to the term and its meaning; but it is evident that it was a n.e. wind, or e.n.e., with variable and fierce gusts from various points—similar to our *northeasters*. It was probably one of those violent gales now called *levanters*. See ETESIAN WINDS.

EUROPA, in Greek mythology, a daughter of Agenor or of Phœnix. Her beauty attracted the attention of Zeus, who appeared in the form of a white bull and carried her to Crete, where she became the mother of Minos, Rhadamanthus, and Sarpëdon. Her brother Cadmus, strictly charged not to return without her, set out with their mother (Telephassa) to find her. The mother died in Thessaly. At Delphi, Cadmus

learned that he must follow a cow, which would guide him to the place where he must build a city. The cow lay down on the site of Thebes; but before he could offer the animal as a sacrifice to Athene he had to fight with a dragon which haunted a well. He conquered the dragon, and sowed its teeth over the ground. From the teeth sprang armed men who slew each other until only five were left to become the progenitors of the Thebans. Athene made Cadmus king of Thebes, and Zeus gave him Harmonia as his bride. The fate of Europa is not further recorded, but her name still lives in the designation of the continent of Europe.

EUROPE, the smallest, but also the most highly civilized and most populous of the three great divisions of the old continent. It is separated from America on the w. and n.w. by the Atlantic; from Africa on the s. by the Mediterranean; and from Asia by the archipelago, Sea of Marmora, Black Sea, Caucasian ridge, Caspian Sea, Ural River and mountains, and the Kara River. It is in the form of a huge peninsula, projecting from the n.w. of Asia. Its extent from Cape St. Vincent on the s.w. to the mouth of the Kara River on the n.e. is 3,400 m.; and from Cape Nordkyn, the most northerly point of the Scandinavian mainland, to Cape Matapan, the southmost point of Greece, 2,400 miles. The continent of E., irrespective of islands, lies within lat. $36^{\circ} 1'$ to $71^{\circ} 6'$ n., and long. $9^{\circ} 30'$ w. to $68^{\circ} 30'$ east. Its area is estimated at more than 3,800,000 sq. m.; and its coast-line, more extensive in proportion to its size than that of any other great natural division of the globe, is estimated at 31,000 m. This is caused by its great irregularity, and its deep gulfs and inlets. It has a pop. of 328,000,000, which gives an average of about 86 for every sq. mile.

The body of the European continent divides itself naturally into two great portions—the great plain in the n.e., and the highlands in the s.w., the mountainous peninsula of Scandinavia, lying, as it were, apart from either, being to some extent exceptional. The plain occupies about two thirds (2,500,000 sq.m.) of the entire extent of the continent. It reaches from the eastern boundary of E., n. to the shores of the Arctic ocean, s. to Mount Caucasus and the Black Sea, and westward over the whole extent of the continent; gradually, however, becoming narrower in its progress west. In shape, this plain resembles a triangle; its base rests on the eastern boundary, and it may be said to reach its apex on the shores of Holland. It separates the two mountain systems of E.—the Scandinavian system (see SCANDINAVIA) on the n., and on the s. the system of southern Europe. See ALPS, APENNINES, BALKAN, CARPATHIAN MOUNTAINS, CEVENNES, PYRENEES, etc.

Jutting out in numerous peninsulas, and indented by extensive bays and gulfs, E. has no town at a much greater distance from the sea than 400 m., save those in the center of the eastern plain; but even here, by means of numberless rivers and the canals, which, from the nature of the country, are easily constructed and maintained, a splendid system of communication by water now exists. See VOLGA, DÜNA, DNEIFER, NIEMEN, etc. Also RUSSIA.

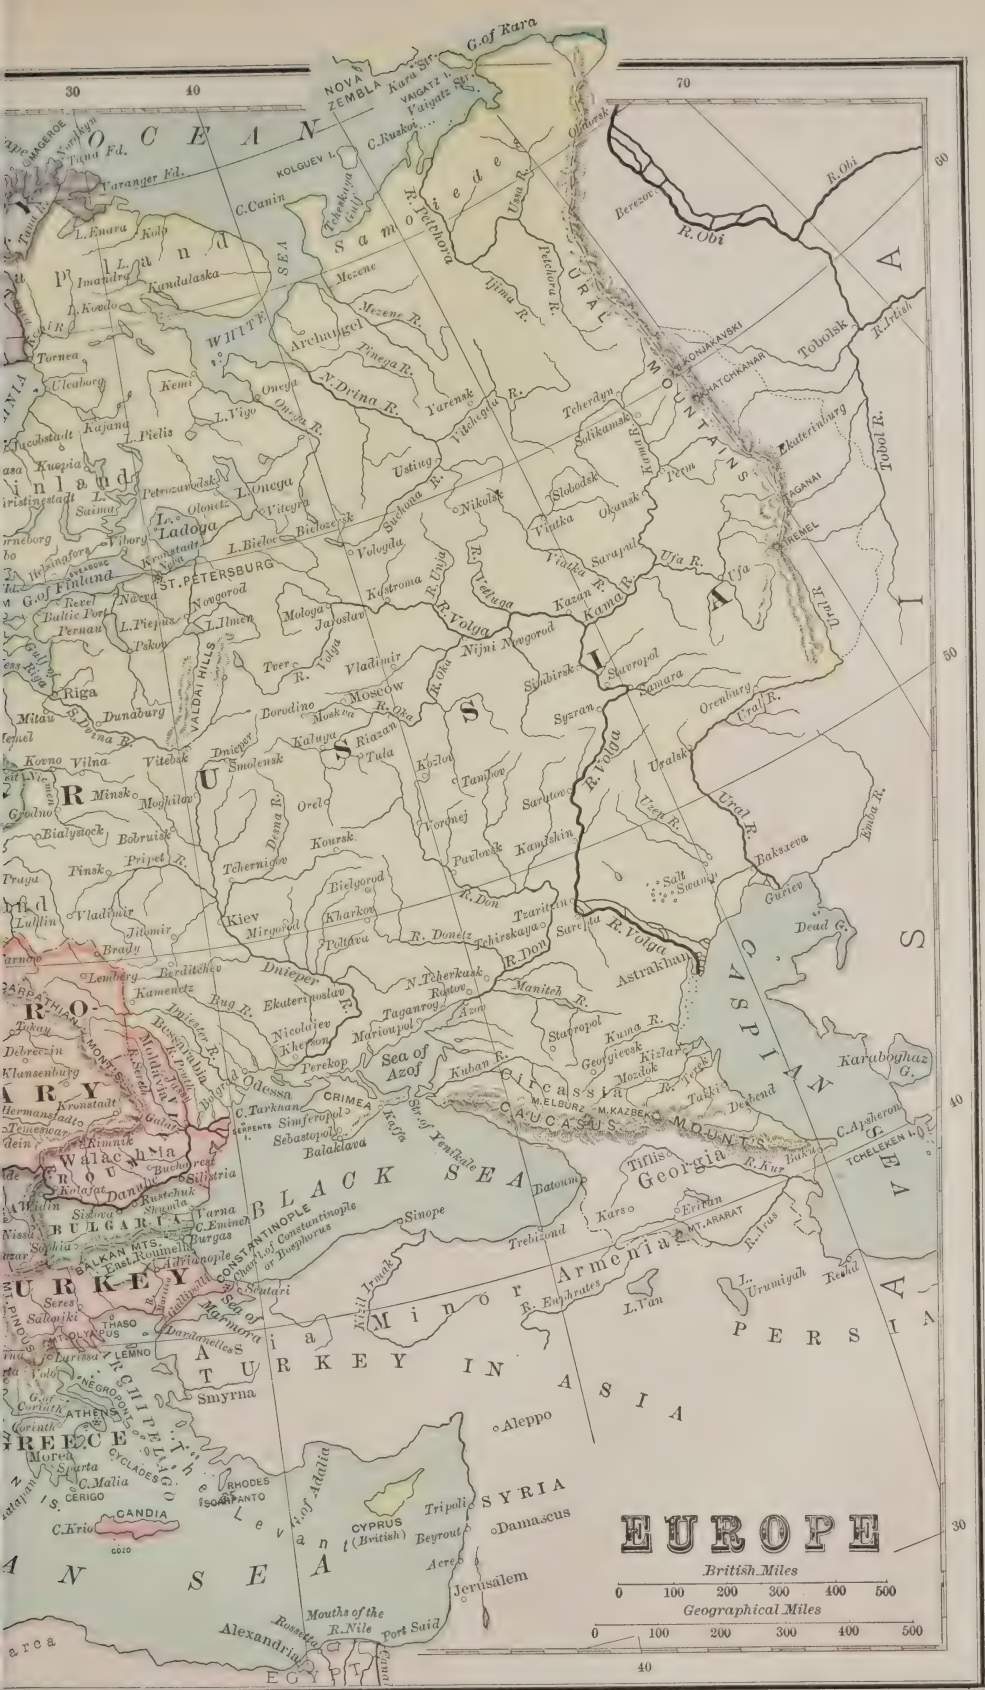

As the details of the geography of E. are given under the names of its several political divisions, and of its lakes, rivers, etc., little falls to be said under the present head. On the opposite page, however, is a table of the countries of E., with their extent, etc.

Geology.—The geology of E. is most conveniently considered under the different countries. See also ALPS, PYRENEES, etc.

Natural History.—The natural history of E. very much agrees with that of the corresponding latitudes of Asia. The natural history of the European countries on the Mediterranean sea is very similar to that of Syria and of Asia Minor. The natural history of the more northern regions of E. resembles that of the great plains of Central Asia and Siberia. The most northern regions have the strictly arctic flora and fauna common in a great measure to all the arctic and subarctic regions; whilst the natural history of the most southern countries assumes a subtropical character. The European countries near the Mediterranean produce fewer of the shrubby and odoriferous *labiateæ* than the Caucasus and adjoining regions, whilst the *caryophyllaceæ* are more abundant. The extreme abundance of *cistaceæ* is a peculiar feature of the flora of Spain and Portugal. The *primulaceæ* are particularly plentiful in all the alpine regions of the s. of E., but this characteristic is in some measure shared by the Himalaya. In no other part of the world do the umbelliferous and cruciferous plants form so large a proportion of the flora as in Europe.

The temperature of the western and northern parts of E. being raised by the gulf-stream and the winds from the great mass of dry and desert land in Africa above what is elsewhere found in similar latitudes, the flora and fauna exhibit a corresponding character, affected, however, by the great amount of moisture derived from the Atlantic ocean; and also to a still greater degree by the comparative uniformity of temperature which the proximity of the ocean produces. The effect of the last-mentioned causes is so great, that the northern limit of some plants is sooner reached on the shores of the Atlantic than in the more central parts of E., where the winters are much colder, and the average temperature of the year is lower. Of this the vine and maize are notable examples. Plants which require a mild winter will not grow in the n.—and scarcely even in the center of E.—but they advance along the western coast under the influence of the maritime climate. Thus the myrtle—although not indigenous—grows even in the

URBANA

s. of England. Amongst plants, the date palm, and amongst animals a species of **ape**, are found in the s. of E. (the ape only on the rock of Gibraltar); whilst some strictly African birds are frequent visitants, and many birds—as the cuckoo, swallow, etc.—are common to E. and Africa, inhabitants in summer even of very northern regions, and returning in winter to the warm south.

Of the plants now most commonly associated in our thoughts with the southern countries of E., many have probably been introduced from Africa, or from the east. This has probably been the case even with the myrtle, and certainly has been the case with the vine, the olive, the orange, lemon, etc., the fig, the peach, the almond, the apricot, etc. Some of the most extensively cultivated fruits are certainly indigenous to E., as the apple, pear, plum, and cherry, although even of these the first improved varieties may have been introduced from the earlier seats of civilization in the east. Among the wild animals of E. at the present day, the aurochs or bison is still reckoned; and the ox existed at no very remote period in a truly wild state. The reindeer

* These statistics are given according to actual censuses taken between 1879 and 1891.

† Including the principalities of Lübeck and Birkenfeld.

inhabits the extreme n. of E.: the elk, the stag, the fallow-deer, and the roebuck, are found in more southern nations; the ibex or bouquetin exists on the high central mountains; two species of antelope—the chamois of the Alps, and the saiga of the Russian plains—connect the European fauna with the Asiatic and African. Of carnivorous animals, the most worthy of notice are the bear, the wolf, the fox, and the lynx.

The abundance of lakes and streams in the northern parts of E. is accompanied with a corresponding abundance of water-fowl (*anatidæ*) and of fish. Of the latter, the *salmonidæ* are the most valuable, and the *cyprinidæ* next to them. The European seas afford valuable fisheries, particularly of herring and of cod in the n., and of tunny, anchovy, etc., in the Mediterranean.

The common hive bee and the Ligurian bee may probably be regarded as natives of Europe. The silk-worm was introduced from the east. Another valuable insect, the cochineal insect, was introduced from America; but the *cantharis*, or blistering fly, is truly indigenous to the s. of Europe.

EUROTAS, a river of Greece now called the Vasiliko, rising in the Arcadian mountains and falling into the gulf of Laconia. The cities of Sparta and Amyclæ were on this river, which was one of the streams to which the ancient Greeks paid divine honors.

EURYALE, a genus of plants of the natural order *nymphæaceæ*, or water-lilies, closely allied to *Victoria* (q.v.), although of very different appearance. *E. ferox* is a water-lily with small red or violet-colored flowers, leaves about a foot in diameter, the leaf-stalks and calyces covered with stiff prickles; a native of India and China. The fruit is round, soft, pulpy, and of the size of a small orange, composed of a number of carpels, and containing round black seeds as large as peas, which are full of a nutritious agreeable farina, and are eaten roasted. The root-stock also contains starch, which may be separated and used for food; and the root itself is eaten. The plant is said to have been in cultivation in China for upwards of 3,000 years.

EURYDICE, the wife of Orpheus. She died from the sting of a serpent, and her husband followed her into hades, where he so charmed Pluto with the music of his lyre that he was permitted to take Eurydice back to earth on condition that while on his way he would not look behind him. Just as they were near the entrance Orpheus could no longer refrain from casting a backward glance, which showed him Eurydice rapidly receding to the regions of the dead.

EUSEBIUS, of Cæsarea, the father of ecclesiastical history, was b. in Palestine, about 264 A.D. He took the surname of Pamphili from his friend Pamphilus, bishop of Cæsarea, whom he faithfully attended for the two years (307-309) in which he suffered imprisonment during the persecution of Diocletian. He then went to Tyre, and afterwards to Egypt, where he himself was thrown into prison on account of his religion. In 315, he succeeded Agapius as bishop of Cæsarea, took a prominent part at the council of Nice in 327, and died about 340.—E. was the head of the semi-Arian or moderate party in the council of Nice. That party were averse to discussing the nature of the Trinity, and would have preferred the simplicity of Scripture language in speaking about the Godhead to the metaphysical distinctions of either side. They regarded Trinitarianism, on the one hand, as logically indefensible, but, on the other, they recognized the fact, that Scripture sometimes spoke of the Son in terms not compatible with the views of Arius, and therefore they wished each man to enjoy the utmost freedom in his interpretation of Scripture on this point. E. thought that the great thing was to lay to heart the truth, that "God so loved the world that he gave his only begotten Son, that whosoever believeth on him should not perish, but have everlasting life." The promise is to him that *believeth on him*, not, he argues, to him that *knows how he is generated from the Father*. He was very reluctant to accept the term *homoousios* (of the same substance), devised by Athanasius to describe the equality of the Son with the Father, and retained the kindest feelings towards Arius after the views of the latter were condemned. His moderation and other excellent qualities procured him the favor of Constantine, who declared that he was fit to be the bishop of almost the whole world. E. has the reputation of being the most learned Father of the church after Origen. His chief works are—1. The *Chronicon*, a history of the world down to the celebration of Constantine's *Vicennalia* at Nicomedeia and Rome, 327 and 328 A.D. It is valuable as containing extracts from such writers as Berosus, Sanchoniathon, Polyhistor, Cephalion, and Manetho. It was first published in a complete state by Mai and Zohrab, at Milan, in 1818, from an Armenian MS. version discovered at Constantinople. 2. The *Preparatio Evangelica*, in 15 books, a collection of such statements in old heathen authors as were fitted to make the mind regard the evidences of Christianity in a favorable light. It was translated into Latin, and appeared at Treviso in 1480. The Greek text was first published at Paris in 1544. 3. *Demonstratio Evangelica*, in 20 books, a work intended to convince the Jews of the truth of Christianity from the evidence of their own Scriptures. A Latin version of this was printed as early as 1498; the Greek original did not appear till 1544, when it was published along with the *Preparatio* at Paris, by R. Stephens. 4. The *Ecclesiastical History*, in 10 books. This relates the principal occurrences which took place in the Christian church till the year 324,

and contains the results of his studies in numerous libraries, and even in the imperial archives, the emperor Constantine having ordered, at E. 's request, an examination of all documents relative to the history of martyrs. One drawback of the work is that E., on principle, withholds all account of the wickedness and dissensions of Christians, inasmuch as he did not consider such stories for the edification of the church. A Latin translation of the work by Rufinus was published at Rome in 1474; the Greek text at Paris in 1549, and at Geneva in 1612. Among the more recent editions are those of Heinichen (Leib. 1827) and Burton (Oxford, 1838). The *Ecclesiastical History* has been translated into English, German, French, etc. Besides the foregoing works may be mentioned the *De Martyribus Palestinæ*, a book against Hierocles; another against Marcellus; and a *Life of Constantine*. The first edition of all E.'s works appeared at Basel in 1542. See the life of Eusebius by Hély (1877).

EUSEBIUS, of Emesa, was b. at Edessa, studied at Alexandria, and was the pupil of Eusebius Pamphili, and the friend of Eusebius of Nicomedeia. Averse to all theological controversies, he declined the bishopric of Alexandria, vacant by the deposition of Athanasius. He was afterwards, however, appointed bishop of Emisa, but during his ordination, a Christian mob, accusing him of "mathematics" and magic, created a tumult, and obliged him to flee for his life. Subsequently, he returned to Emisa, where he was "tolerated" in spite of his dangerous knowledge. He died at Antioch in 360. The emperor Constantius was much attached to E., and used to take him with him on his military expeditions. E. was accused of Sabellianism (see SABELLIUS), and Jerome calls him "the ringleader of the Arian party." Jerome, however, was rash in his epithets, and it is more probable that he belonged to the party of his namesake of Cæsarea, the semi-Arians, or peace-party, who wished the doctrine of the Godhead expressed in the language of Scripture, and not of theology. The homilies extant under his name have been published by Augusti (Elberf. 1829). The genuine ones display great eloquence. Other writings by him, as, for example, the *Questiones XX. Evangelicæ*, and part of the *Commentarius in Lucam*, were published by Mai, in the *Scriptorum Veterum Nova Collectio* (vol. i., Rome, 1825). See Thilo, *Ueber die Schriften des E. von Emesa* (Halle, 1832).

EUSEBIUS, of Nicomedia, Patriarch of Constantinople, b. towards the end of the 3d c., was first tutor to the emperor Julian, to whom he was related by the mother's side; then bishop of Beryta (Beyrout), in Syria, and afterwards of Nicomedia. In order to secure his position, he appeared as the defender of Arius at the council of Nice, and afterwards placed himself at the head of the Arian party. Under the emperor Constantine, whom he baptized in 337, he became patriarch of Constantinople. He died in the year 342, after having, in the previous year, held an assembly of the church for the establishment of Arianism at Antioch. It is not easy to get at his real character. We have no ecclesiastical works by Arian writers, our only sources of information as regards the character and opinions of that party being their enemies—the orthodox party; yet, making the ordinary allowance for partisanship, there would seem to be sufficient reason for concluding that E. was cunning and double-tongued when occasion required, and imperious and violent when he had power in his hands. Athanasius considered him not the disciple, but rather the teacher of Arius. From him the Arians are sometimes styled Eusebians. See Neander, *Kirchengeschichte*, vol. ii. p. 773, etc.

EUSTACHIAN TUBE. See EAR.

EUSTACHIAN VALVE. See FÆTUS.

EUSTACHIUS, BARTOLOMEO, an Italian anatomist, who was b. in the early part of the 16th c., and died in 1574. Few particulars are known regarding his life, but we learn from the introduction to one of his works, that in 1562 he was professor of medicine in the Collegio della Sapienza at Rome. His name is indelibly associated with anatomical science, through his discoveries of the tube in the auditory apparatus, and the valvular structure in the heart, which have been called after him. He was the first to give an accurate description of the thoracic duct, and was probably the first to notice and describe the stapes (one of the chain of small bones crossing the tympanic cavity of the ear), a discovery which, however, Fallopius assigns to Ingrassias. He likewise contributed materially to the diffusion of more accurate knowledge regarding the development and evolution of the teeth, and the structure of the kidney. These discoveries are recorded in his *Opuscula Anatomica*, published at Venice in 1563. He was the first anatomical writer who illustrated his works with good engravings on copper. The *Tabula Anatomica*, which he was probably unable to publish in consequence of the poverty of which he complains in the introduction to which we have already referred, did not appear until 1714, when they were edited, with explanatory remarks, by Lancisi. Their value is sufficiently evidenced by the fact, that Albinus published a new edition, with an excellent Latin commentary, in 1743, at Leyden; that Bonn published a Dutch edition in 1798 at Amsterdam; and that a German edition appeared in 1800. Lauth, in his *History of Anatomical Discovery*, remarks that if the *Tabula* had appeared in E.'s lifetime, anatomy would have attained the perfection of the 18th c. nearly 200 years earlier. E., Vesalius, and Fallopius may be regarded as the three great founders of modern anatomy.

EUSTATHIUS, the celebrated Greek commentator on Homer and the geographer Dionysius, was born at Constantinople. He was at first a monk, then a deacon and teacher of rhetoric in his native city, and, in the year 1155, was appointed archbishop of Thessalonica, where he died in 1198. E. was profoundly versed in the ancient classic authors, and a man of prodigious acquirements, as is proved by his commentaries. The number of authors whom he quotes is almost incredible, and the value of his quotations is heightened by the consideration, that most of the works from which he extracts are no longer extant. His most important work is his *Commentary on the Iliad and Odyssey of Homer*. The first edition appeared at Rome 1542-50; the last at Leip. 1825-29. The work is open to objection on the score of method, and is diffuse and digressive, but it is nevertheless a vast mine of knowledge for students of Homer. Of a similar character is E.'s *Commentary on Dionysius*, first printed by Stephens (Paris, 1547), and lastly in Bernhardy's edition of Dionysius (Leip. 1828). Of his commentary on the hymns of Pindar, only the *Proœmium* has come down to us. It was first published by Tafel in 1832.

EUSTATHIUS, SAINT, a native of Pamphylia; bishop of Beroœa, and in 325 A.D. patriarch of Antioch. He was a zealous opponent of the Arians, who contrived to have him deposed on charges of heresy and unfaithfulness to the vows of celibacy. He was banished to Thrace, where he died about 360 A.D.

EUSTATIUS, ST., one of the Dutch West India islands, lies near the n.e. bend of the great arch of the Antilles, about 12 m. to the n.w. of St. Christopher. Lat. 17° 31' n., and long. 63° 5' west. Area, 8 sq. miles. St. E. is a pyramidal rock, of volcanic formation, showing two extinct craters, and being still subject to earthquakes. Hurricanes also of intense severity occur, more particularly in Aug. and Sept. Along its entire circuit of 29 m., St. E. has only one landing-place.

EUSTIS, JAMES BIDDLE, b. New Orleans, 1834; practiced law in La.; served in the civil war as judge-advocate on the staffs of Gens. Magruder and Johnston. He was elected as a democrat to the U. S. senate, 1876 and 1884, retired in first term in 1879, and was professor of civil law in the University of Louisiana till his re-election; and was U. S. minister and first ambassador to France in 1893-7.

EUSTIS, WILLIAM, LL.D., 1753-1825; b. Mass.; a graduate of Harvard; studied medicine under Dr. Joseph Warren; served as a surgeon in the revolutionary army, and in the hospitals. He was a member of the state legislature, a member of the council; twice a member of congress; secretary of war, 1809-12; minister to Holland, 1814; governor of Massachusetts in 1824, and died while in office.

EUTAW SPRINGS, BATTLE OF, Sept. 8, 1781; between the American revolutionists under Gen. Greene, and the British under Col. Stuart. The British retreated, losing about 630 men; the American loss was 535. The scene of the battle was about 60 m. n.w. of Charleston, S. C.

EUTERPE (i.e., she who delights), one of the nine muses, was the daughter of Zeus and Mnemosyne. She was the muse of lyric poetry, and is represented in ancient works of art with a flute in her hand. See **MUSES**.

EUTHANASIA (Gk.), an easy death, or a painless method of putting to death. The use of narcotics or other means for shortening life, in disease, has never become a subject of discussion in modern civilized countries; but it is often a very practical question as to how far such means are admissible for soothing the last hours of life, when the approach of death does not of itself dull the consciousness and the sensibility to pain. It must be decided according to all the surrounding circumstances, medical and otherwise, in each individual case. As to the medical treatment, see Munk's *Euthanasia* (1887).

EUTROPIUS, a Latin historian, concerning whom we only know that he filled the office of secretary to the emperor Constantine, fought against the Persians under Julian, and was still alive in the reign of Valens. The period of his death is unknown. His *Breviarum Historiæ Romanæ*, giving a short narrative of Roman history from the foundation of the city to the time of the emperor Valens, is written in an extremely simple and pure style, and appears to have been originally intended for the use of schools. It became very popular as the taste for original investigation declined, in that dark period between the death of the old world and the birth of the new; and is either copied or followed by the early monkish annalists. An edition, with enlargements, however, was published by Paul, son of Warnefrid and Theodolinda, generally known as Paulus Diaconus. Others continued it down to the year 813. The history existed in three distinct forms at the revival of letters: there was first the genuine work of E. in ten books; second, the expanded editions of Paul; and third, a very complete, but also largely interpolated copy contained in the *Historia Miscellæa*. The editio princeps, printed at Rome in 1471, was from the impure text of Paul. The best editions in modern times are those of Tzschucke (Leip. 1796, improved 1804), and of Grosse (Halle, 1813; Leip. 1825), and Droysen (1879).

EU'TYCHES, a Byzantine ecclesiastic of the 5th c., and a zealous but unskillful representative of the dogmatic opinions of Cyril of Alexandria. In opposing the doctrines of Nestorius, he fell into the opposite extreme, and taught that after the union of the two natures in Jesus Christ, the human nature was absorbed in the divine; an opinion which spread extensively through the Alexandrian church. E. was in consequence summoned before a synod at Constantinople in the year 448, and deposed by Flavianus,

patriarch of that city; but his cause was warmly espoused by the eunuch Chrysaphius, chief minister of the emperor Theodosius II., and Dioscurus, bishop of Alexandria, who were both opposed to Flavianus. Chrysaphius induced the emperor to call a general council at Ephesus in the following year, under the presidency of Dioscurus. Measures were taken beforehand to secure a triumph over the anti-Eutyrians. Soldiers were admitted to the deliberations of the council, to overawe the party of Flavianus; while a crowd of fierce Egyptian monks, devotedly attached to whatever was popular in Alexandria, or had been countenanced by their old pupil Cyril, drowned by their fanatical outcries the voices of those who ventured to speak against Eutyries. The result was that the judgment of the previous council was reversed; Flavianus and his adherents were deposed, and the doctrine of E. affirmed to be orthodox, and in accordance with the Nicene creed. His triumph, however, lasted only two years; in 451, Eutyrianism was pronounced heresy at the council of Chalcedon, attended by 650 bishops; and in opposition to his views, it was declared that in Christ the two natures were united without confusion or conversion of substance. Nothing further is known concerning E., except that Leo wrote to the emperor Marcian to banish him from the capital. The sect of Eutyrians, however, under the name of Monophysites, continued to exist quietly for a century after his death, in the Armenian, Ethiopian, and Coptic churches, when it awoke to new life under the auspices of Jacob Baradæus, who died bishop of Edessa, 588 A.D. His followers were called Jacobites, and have perpetuated the Monophysite doctrine in the Armenian and Coptic churches to the present day. See Neander, *Kirchengeschichte*, vol. iii., p. 1079, etc.

EUXINE (Gr. *euxinos*, hospitable) is the name applied by the ancients to the Black sea (q.v.).^a Before receiving this name it was called *Aænos Pontos*, the inhospitable sea, because of the black and turbulent weather so frequently ascribed to it by the ancient poets, and the reported cannibalism of the Scythian tribes who lined its northern shores. It seems to have been called the *Euxine*, or hospitable sea, after the establishment of Greek colonies on its borders, and when its waters were thrown open to Greek commerce.

EUYUK, or **Uruk**, a Turkish village in Asia Minor, 75 m. w.s.w. of Amasia. It has but about 20 houses, but is important as containing some of the most remarkable ruins in the east. They are the remains of a large building, and consist of colossal blocks of granite containing a great variety of sculptures very little defaced. The upper portion of the wall seems to have been formed of clay, as there are no remains of overturned materials. In form the building resembles an Assyrian palace, and has been conjectured by some to have been erected by the builders of the palaces of Nineveh, adopting in this instance, as they are known to have done in others, Egyptian figures.

EVACUATION DAY. On November 25, 1783, after the treaty of peace was signed, the British troops finally evacuated the city of New York. This was called Evacuation Day, and was celebrated as a public holiday until within the last fifteen years.

EVAGORAS, King of Salamis, 410 B.C. Isocrates says he was a just and wise ruler, who promoted the welfare of his people. He cultivated the friendship of the Athenians, and after Conon's defeat at Ægospotami gave that officer a refuge. He made friends of the Persians, and assisted them and the Athenians in gaining the victory of Cnidus, 394 B.C. In 387, he was at war with the Persians, but soon made peace. He was assassinated 374 B.C.

EVA'GRIUS, b. Syria, 536 A.D. He was an advocate at Antioch, and the legal advisor of Gregory, the patriarch. The emperor Tiberius made him a quæstor, and his influence and reputation were such that on the occasion of his second marriage he was given a public festival, which, however, was interrupted by an earthquake, in which 60,000 persons are said to have perished. He was the author of a valuable *Ecclesiastical History*.

EVAN DER, a semi-mythical Grecian hero of antiquity, was, according to Roman traditions, the son of Hermes, by Carmenta or Tiburtis. About 60 years before the Trojan war, he is said to have led a Pelasgian colony from Pallantium, in Arcadia, to Italy, and to have landed on the banks of the Tiber, and near the foot of the Palatine hill. Here he built a town, naming it Pallantium, after the one in Arcadia. At a later period it was incorporated with Rome, and is affirmed to have originated the names Palatinus and Palatium. Tradition represented E. as having done much to introduce the habits of social life among his neighbors; he prescribed for them milder laws, and taught them, among other arts, those of music and writing. To him is also ascribed the introduction of the worship of the Lycean Pan, with that of Demeter, Poseidon, and other deities. Virgil represents him as being still alive when Æneas arrived in Latium after the sack of Troy. E. was worshiped both at Pallantium, in Arcadia, and at Rome.

EVANGELICAL is an adjective derived from the Gr. *euangelion*, "good news," or "the gospel," and is applied in general to anything which is marked by the spirit of the gospel of Jesus Christ. Thus, we speak of an E. sermon, of E. piety, E. views, etc., though it is but right to mention that the term "E." in such a connection is used

by a portion of the religious community to denote, not so much a spirit or sentiment resembling that of the Saviour, but certain peculiar theological opinions, which are held to constitute the only true and complete expression of Christian belief. In England and Scotland, dissenters have generally laid claim to be considered more "E." than the national churches—i.e., they conceive that they have borne, and still bear, more decided testimony than their brethren of the establishment to the truth of such doctrines as the total depravity of human nature, the imputation of Adam's sin to his posterity, the expiatory character of Christ's sufferings, justification by faith in the atoning efficacy of these sufferings, etc. In the Anglican church, however, the rise of the Puseyite or Tractarian party has brought into prominence an antagonistic party, resembling dissenters very much in their theological tenets. This party calls itself, *par excellence*, "evangelical."—In Germany, all Protestants call themselves E., in opposition to Catholics, on the ground that the reformers taught the pure gospel of the grace of God in Christ, cleansing it of all human corruptions. The modern orthodox or pietistic party in the German Protestant churches have of late made exclusive claim to the attribute E., on the ground that they alone hold to the gospel in its actual historical shape. This claim is naturally disputed by the liberal theologians.

EVANGELICAL ALLIANCE. This voluntary association of Evangelical Christians belonging to various denominations and countries, had its origin in a general and strong desire for a more practical union among Protestants in order to promote the cultivation of Christian fellowship and the extension of Christian faith. After full conference and correspondence the alliance was formed in Freemason's hall, London, Aug. 19-23, 1846, at a meeting, of about 800 persons, Episcopalians, Presbyterians, Independents, Methodists, Baptists, Lutherans, Reformed, Moravians, and others. Among these were many distinguished ministers and philanthropists from Great Britain, Germany, France, Switzerland, and the United States. The following doctrinal articles were adopted, not as a binding creed, but simply as an expression of the points of faith considered essential among those who are embraced in the alliance. 1. The divine inspiration, authority, and sufficiency of the Holy Scriptures. 2. The right and duty of private judgment in the interpretation of the Holy Scriptures. 3. The unity of the Godhead and the Trinity of the persons therein. 4. The utter depravity of human nature in consequence of the fall. 5. The incarnation of the Son of God, his work of atonement for the sins of mankind, and his mediatorial intercession and reign. 6. The justification of the sinner by faith alone. 7. The work of the Holy Spirit in conversion and sanctification. 8. The immortality of the soul, the resurrection of the body, the judgment of the world by our Lord Jesus Christ, with the eternal blessedness of the righteous and the eternal punishment of the wicked. 9. The divine institution of the Christian ministry and the obligation and perpetuity of the ordinances of baptism and the Lord's supper. The organization thus happily commenced has since been extended throughout Protestant Christendom. Branch alliances have been formed in Great Britain, Germany, France, Switzerland, Sweden, the United States, Australia, and among the missionaries in Turkey, India, Brazil, and Japan. These national branches are related to each other as members of a confederation having equal rights. The whole alliance appears in active operation only when it meets in general conferences having the character of Protestant ecumenical councils, but claiming only moral and spiritual power. These have already been held at London, 1851; Paris, 1855; Berlin, 1857; Geneva, 1861; Amsterdam, 1867; New York, 1873; Basle, 1879; Copenhagen, 1885. The most effective of these was the one at New York, when, for the first time, Christians from all parts of the earth met together in the new world to take counsel concerning the condition of Christendom, Christian union, Christian life, Christianity and unbelief, Christianity and error, Christianity and civil government, Christian philanthropy, and reform of social evils. The visible results of the E. A. may be seen, in part, in its promotion of religious liberty wherever that has been restricted or assailed. Since its organization several cases of persecution have occurred in southern Europe under the operation of penal laws against Protestants. In these cases the influence of the alliance has been successfully exerted to bring the persecution to an end. It has aided in bringing about the remarkable changes in favor of religious liberty which have taken place in Turkey within the last quarter of a century. It interceded for the Methodists and Baptists in Sweden, and that country has since abrogated its penal laws against dissenters. It sent a delegation in 1871 to the czar of Russia to plead for the Lutherans in the Baltic provinces, and since that time they have not been oppressed. It remonstrated against the persecution of Roman Catholic and other Christians in Japan, and the persecution has not been renewed. These instances are sufficient to show that the power of Christian public sentiment, as expressed by the alliance, already commands a respectful hearing everywhere, and must, ultimately, be universally obeyed.

EVANGELICAL ASSOCIATION, called sometimes, but incorrectly, the German Methodist church, is a sect of American Christians, originally of German descent, formed under the influence of the Rev. Jacob Albright, who, looking with regret on certain doctrines and habits prevalent among the German churches of eastern Pennsylvania, endeavored to reform them. A meeting of his converts in 1800 chose him as their pastor or bishop, and gave him jurisdiction as such over the members of the association. Subsequently annual conferences were established, and in 1816 a general conference,

consisting of all the elders, met in Union county, Penn. Since 1843, general conferences, consisting of delegates from the annual conferences, have been held every four years. During its earlier years the E. A. was violently opposed, but for the last half century it has been quiet and prosperous. As it denounced slavery it made no progress in the southern states, but it has spread over the n., into Canada and even Germany. In theological doctrine it is described as endeavoring to blend Calvinistic and Arminian views; in polity, worship, and plans of work it resembles the Methodist Episcopal church; the ministers are divided into elders and deacons; the bishops (elected by the general conference) and the presiding elders (elected by the annual conference) continue in office four years, and may be re-elected. At first, preaching and other public services were conducted almost exclusively in the German language; now, however, the English also is employed. The denomination has a flourishing college at Naperville, Ill. In 1889, it reported 26 annual conferences, 1845 preachers (itinerant and local), 1808 houses of worship, 501 parsonages, 145,703 church-members, 2189 Sunday-schools. The Evangelical Association and the united Evangelical churches reported, in 1894-5, a membership of 147,849, with 2945 houses of worship.

EVANGELICAL CHURCH CONFERENCE, is the name given to periodical meetings of the Protestant churches of the German states, the holding of which was suggested by king William of Württemberg in 1815. The first was held at Berlin in 1846, and included representatives from nearly all the German states. At the second, held at Eisenach in 1852, a central organ was established at Stuttgart. From 1855 to 1868, the conferences were held at Eisenach.

EVANGELICAL COUNSELS are given by the Roman Catholic church when it recommends certain things to any one who is willing to practice them, not as in themselves obligatory, but as conducive to the attainment of superior holiness. Among them the principal are celibacy, poverty, and submission to monastic rules. Some writers include under this title various Scripture directions, such as "Resist not evil;" "If any man will sue thee at the law and take away thy coat, let him have thy cloak also;" "Whosoever shall compel thee to go a mile, go with him twain."

EVANGELICAL UNION, the name assumed by a religious body constituted in Scotland in 1843 by the Rev. James Morison of Kilmarnock (later Dr. Morison of Glasgow), and other three ministers (with their respective adherents), who had been separated from the United Secession church for doctrinal views, of which the fundamental and determining article was the strict universality of the Saviour's atonement. Coeval with the body is its theological academy, presided over by Dr. Morison, and attended by over twenty students annually. They were soon joined by a number of ministers and churches of the Congregational union of Scotland, and have since extended themselves considerably in Scotland and the n. of England. Their church government is independent, but many congregations have ruling elders. Their doctrinal views are exhibited in an authorized publication, entitled *Doctrinal Declaration*, issued in Sept., 1858. See **MORISONIANISM**.

EVANGELIST, literally, a bringer of good tidings. It designates, in the New Testament, a person appointed by an apostle to itinerate among the heathen, and so prepare the way for resident instructors. The evangelist, therefore, had no particular flock assigned to him, and is to be distinguished both from bishops and ordinary pastors. Later in the history of the early church, the evangelist figures, according to Eusebius, as "a deliverer of the written gospels to those who were ignorant of the faith." This may possibly imply that he acted as a colporteur, by distributing copies of the gospels, or that he read them to the heathen, and so made them familiar with their contents.—The word evangelist is also used to denote the four writers of the life and gospel of Jesus Christ, these being evangelists ("bringers of good tidings") *par excellence*.

EVANGELISTS, SYMBOLS OF THE FOUR. For Matthew; a man holding a pen and scroll, looking over his left shoulder at an angel: Matthew's was the first gospel, and the angel represents the dictator of it. For Mark; a man writing, and at his side a winged lion couchant, emblematical of the resurrection which is most fully described by this evangelist. For Luke; a man with a pen looking over a scroll, and near by an ox or cow chewing the cud; the latter figure refers to the eclectic character of the third gospel. For John; a young man of delicate appearance, with an eagle in the background to denote sublimity. The more ancient symbols were: for Matthew, a man's face; for Mark, a lion; for Luke, an ox; for John, a flying eagle: all alluding to the four cherubim before the throne of God, described in the *Revelation*.

EVANS, Lieutenant-general Sir DE LACY, G.C.B., 1787-1870; b. Ireland; entered the British army in 1807, and in 1814 was present as lieutenant-colonel of infantry at the capture of Washington, the attack on Baltimore, and the operations before New Orleans. He was in parliament, 1833-41, and 1846-65, representing the "advanced liberals," but in 1835 commanded the British auxiliary legion in Spain, with distinction, and quickly rising in rank, was appointed, on the outbreak of the Crimean war, to command the second division of the army sent to the Crimea, receiving many honors for his gallant conduct during the war.

EVANS, FREDERICK WILLIAM, b. England, 1808; came to the United States in 1820; returned to England, and became interested in Owen's theories and joined the Shakers. Returning to the United States, he soon became a leader of the Shakers, residing at Mount Lebanon, N. Y. He published a number of works on the history and doctrines of the Shakers, and on religious subjects. He d. in 1893.

EVANS, HUGH DAVEY, LL.D., 1792-1868; b. Baltimore; American author. He was admitted to the Baltimore bar in 1815, and attained eminence as a constitutional lawyer. He was very prominent in the councils of the Protestant Episcopal church; from 1843-58 edited several religious newspapers; from 1852-64 was lecturer on civil and ecclesiastical law in St. James' coll., Maryland. Author of *Treatise on the Christian Doctrine of Marriage* (N. Y., 1870), etc.

EVANS, MARY ANN or MARIAN, known under the pen name of "George Eliot," was b. in Chilvers-Coton parish, Warwickshire, England, Nov. 22, 1819. Her father, who was of Welsh descent, was a land agent who had begun life as a carpenter. In 1836, her mother died, and in 1841 the family removed to the vicinity of Coventry, where she became intimate with the Brays and Hennells, families whose influence over her was decided and led her from ardent evangelical belief into skepticism. In 1846, she began her literary career by translating Strauss's *Leben Jesu*, and subsequently, Feuerbach's *Essence of Christianity*. On the death of her father, in 1849, she went abroad and on her return became associate editor of the *Westminster Review*. In 1851 she became acquainted with George Henry Lewes (q.v.), who had separated from his wife, and up to his death in 1878, the two lived together as man and wife. She began to write fiction in 1856, and during 1857 there appeared in *Blackwood's Magazine*, with the signature of George Eliot, a series of stories under the title of *Scenes of Clerical Life*, the very unusual merit of which instantly attracted attention. They seemed to proclaim with great distinctness the advent of a new novelist of fresh and original power. It was from the first sufficiently well understood that the signature was a mere *nom de plume*; and no little curiosity was excited as to the personality of the author unknown. This feeling was much deepened by the publication in 1859, by the Messrs. Blackwood, of the novel of *Adam Bede*, which attained an immense success, and at once secured for the writer almost undisputed rank with the most eminent novelists of the day. This was followed, in 1860, by *The Mill on the Floss*, which amply sustained the reputation of the writer; and in 1861 by *Silas Marner, the Weaver of Raveloe*, a tale in one volume, which, as to art, is perhaps the most perfect of any of this series of works. In 1861, the *Scenes of Clerical Life* were republished from *Blackwood's Magazine*, to meet with a renewal of the favor with which they were originally received; and in 1863, *Romola*, an elaborate historical novel of Italian life, was published by Messrs. Smith, Elder & Co., in whose *Cornhill Magazine* it had previously from month to month appeared. This work has never had quite the popularity of its predecessors, but is considered by a selecter circle of readers—and perhaps on the whole with justice—the greatest intellectual effort of the author. Meantime—though the avowal has never in any formal fashion been made—it had by degrees become positively certain that Miss E. was the "George Eliot" of these works; and by not a few competent critics a place had been frankly assigned her at the very summit of this branch of our literature. *Felix Holt, the Radical*, published in 1866 by Messrs. Blackwood, was distinctly the book of the season, and was almost everywhere received with acclamation. *Middlemarch, a Study of English Provincial Life*, began to be published in divisions by Messrs. Blackwood in 1871. It was completed in 8 divisions, the last of which was issued in 1872, and simultaneous with it the entire work appeared in 4 vols. The divisions had an enormous circulation, and enhanced Miss E.'s great reputation. *Daniel Deronda* was published in the same way in 1876. Miss Evans also published poetry of a high degree of merit. *The Spanish Gypsy* was published by Messrs. Blackwood in 1868; in 1869 appeared *Agatha, a poem*; in 1870, *The Legend of Jubal*, a poem of great power; and in 1871, *Armgarth, a dramatic poem*. In 1879 appeared a volume of essays, *The Impressions of Theophrastus Such*.

In May, 1880, she was married to John Walter Cross, a rich English merchant, 10 or more years her junior, who in 1885 published *George Eliot's Life*. She died Dec. 22, 1880. In 1883, the essays contributed by her to the *Westminster Review* were published. See *George Eliot*, by Mathilde Blind (1883); *The Ethics of George Eliot's Works*, by John Crombie Brown (London, 1879; Phila., 1885); Hulton, *The Guides of English Thought*.

EVANS, OLIVER, 1755-1819; b. Del. He was apprenticed to a wheelwright, but soon displayed uncommon inventive genius. When 22 years old he invented a machine for making card-teeth which superseded hand work. He made the first high-pressure steam-engine and the first steam dredging machine used in the United States. This was put on wheels and propelled itself to the Schuylkill river, 1½ m.; was fitted with a steam paddle-wheel and navigated the Schuylkill down to its junction with the Delaware. This is supposed to have been the first actual propulsion of a carriage on land by steam in America. He urged the construction of railroads with rails of wood or iron, but was hindered by limited means from carrying out the idea to any practical result.

EVANSTON, a township in Cook co., Ill., on lake Michigan, 12 m. n. of Chicago; on the Chicago and Northwestern railroad; includes the villages of Rogers Park and South Evanston and part of the village of Evanston. There are many churches, banks, a

free library, electric lights, and the Holly system of water-works. Evanston is the seat of Northwestern (Methodist) university, Winchell academy, and the Garrett biblical institute. It has a beautiful situation, many fine buildings, and social attractions of a high order. Pop. tp., '90, 13,059.

EVANSVILLE, city, port of entry, and co. seat of Vanderburg co., Ind.; on the Ohio river, 192 m. above Cairo; 185 below Louisville. It is reached by the Evansville and Terre Haute, Louisville, Evansville and St. Louis, Louisville and Nashville, and other roads. The city was laid out in 1817, and stands on high ground on a bend made by the river. It has a U. S. government building, court-house, U. S. marine hospital, opera house, Evans (temperance) hall, library and art gallery, a fine high-school building, several grammar and parochial schools, numerous churches, a public day school for the deaf, a commercial college, daily, weekly, and monthly periodicals, several national and other banks, and manufactories of flour, iron, malt liquors, furniture, leather, wool, cotton, etc. In 1890 there were 482 manufactories, with \$9,166,859 capital, employing 7435 persons, with products valued at \$12,809,334. The shipment of grain, tobacco, cement, whisky, wheat, pork, coal, etc., is large. Iron ore and coal abound in the vicinity. The city has gas and electric lights, electric street railroads, the Holly system of water-works, and good sewerage. Pop. '90, 50,756.

EVAPORATION, the conversion of a fluid or solid into vapor. Steam, vapors of alcohol, camphor, iodine, etc., are familiar instances. All fluids are surrounded by vapor at common temperatures; but for every substance there is a limiting temperature, below which no E. takes place. The pressure, or tension, of a vapor depends mainly upon the nature of the substance evaporated, and the temperature to which it is raised. The full amount of vapor, however, is not produced instantaneously, and therefore, in general, *time* is an element in the question as well as temperature. See **DIFFUSION**.

The boiling-point (q.v.) is the temperature at which vapor is freely given off—i.e., at which the tension of the vapor of a substance is equal to the atmospheric pressure. Dalton gave an empirical law, which, however, is only at all approximate for temperatures near the boiling-point: "The tension of the vapor of a substance rises in *geometric*, as the temperature rises in *arithmetic*, progression." It is sufficient for our present purpose to notice, that the tension increases very rapidly with the temperature. Some curious consequences result from this. Thus, water boils at 212° F., under a pressure of 30 in., or at that temperature the tension of its vapor is *one* atmosphere. At 162° F., or 50° below its boiling-point, its vapor has a tension of 10 in. of mercury, and it will therefore boil, if placed in the receiver of an air-pump, as soon as two thirds of the air have been extracted.

If a little water be boiled in an open flask till the steam has displaced a great part of the contained air, and the flask be then tightly corked, the water will gradually cool. If the flask be now dipped in *cold* water, boiling recommences, the cold water having condensed some of the vapor, and so diminished the pressure on the contained liquid. Dip the flask in *hot* water, and the boiling ceases. These appearances may be obtained several times in succession.

A fluid cannot be heated above its boiling-point, at the ordinary pressure of the atmosphere; but if it be heated in a closed vessel, the tension of the vapor produced is to be taken in addition to the former pressure, and the boiling-point rises with it. Thus, when the pressure is equivalent to 2 atmospheres, the boiling-point of water is raised 40° F. At such temperatures, its solvent powers are greatly increased. Many minerals which are found in fine crystals are supposed to have been deposited from water which had dissolved them in large quantities, under the combined influences of pressure and temperature. Papin's digester (q.v.) depends upon this principle.

The amount of E. from a fluid depends upon many circumstances. As, except in the case of actual boiling, it takes place only at the surface, the amount of surface exposed is an important consideration where rapid and copious E. is required, as in steam-boilers, salt pans, etc. When, on the contrary, it is desirable to prevent E. as much as possible, a layer of oil, preventing direct contact with the air, is of great use. The rate of E. depends also on the pressure, and varies, according to Daniell, nearly inversely as the latter. His experiments, which appear trustworthy, were made in an exhausted receiver, and the vapor was removed as it was formed.

In the conversion of a fluid into vapor, a quantity of heat disappears; i.e., is required to produce and maintain the gaseous state. Thus, the temperature of steam at 30 in. is the same (to the thermometer) as that of the boiling water from which it comes off; but the heat necessary to convert a pound of water at 212° into steam at 212°, would raise nearly 1000 pounds of water from 60° to 61°. See **HEAT**. When, therefore a fluid evaporates, the vapor carries off heat from the fluid, and thus E. produces cold. This, of course, is matter of daily observation. Porous earthenware jars are employed to cool water in summer in this climate; and in India ice is procured by exposing water in shallow pans, laid on straw, to the combined effects of E. and radiation at night.

On the same principle depends sir John Leslie's method of freezing water. The water is placed in a flat porous dish, over a large surface of strong sulphuric acid, and the whole covered with the receiver of an air-pump. When a good vacuum has been produced, there is, of course, as we have already seen, a rapid E., and the acid eagerly absorbing the vapor as it is formed, the process goes on without further working of the pump, till the residual water has become a solid cake of ice. A most extraordinary

example of this production of cold is afforded by the freezing of water on a white hot plate—by no means a difficult experiment. A platinum capsule is heated nearly to whiteness by a lamp placed underneath; a little water, mixed with sulphurous acid, which is an extremely volatile liquid (indeed it is gaseous at ordinary temperatures and pressures), is poured upon the plate. The acid instantly evaporates, and the cold produced freezes the water, which can be dropped from the hot plate on the hand as a lump of ice.

Another remarkable instance of this occurs in the formation of solid carbonic acid. The liquid acid is forced by the pressure of its own vapor in a fine stream into the air from a nozzle in the strong iron vessel in which it is contained. It evaporates so rapidly in air that a portion of the stream is frozen, and the delicate snow-like mass can be collected by proper apparatus.

Having thus briefly examined some of the circumstances connected with E., we may proceed to mention some of its important bearings on meteorology. In this respect it is one of the most effective of all the gigantic processes that are continually going on around us. Watery vapor is continually rising invisible in the air; meeting with a colder stratum of the atmosphere, or the cold ridge of a mountain, it becomes condensed into mists or clouds; the fine particles of these unite into larger groups, and fall as rain, hail or snow—to be again evaporated by heat from the moist ground, or from rivers, lakes, and seas. Even when otherwise invisible, its presence may be detected by its deposition as dew (q.v.), and, according to Clausius, in the blue of the sky, and the gorgeous tints of sunrise and sunset. There is little doubt of its being also intimately connected with the scintillation of the fixed stars. See SCINTILLATION. Atmospheric electricity is largely due to E. directly as well as indirectly, on account of the amounts of vapor contained in different currents of air. It is matter of everyday observation how much the drying of the ground, or E. generally, is promoted by a brisk wind. This finds its explanation in the constant removal of the vapor as it is formed, the diffusion of the vapor taking place into comparatively dry air instead of the moist atmosphere into which it would take place in a calm. See RAIN and ATMOSPHERIC ELECTRICITY.

EVARTS, JEREMIAH, 1781–1831; b. Vt.; graduate of Yale; admitted to the bar in 1806, and in 1810 became editor of the *Panoplist*, a religious journal in Boston. In 1812, he became treasurer of the American board of commissioners for foreign missions, and in 1821 corresponding secretary. When the *Panoplist* gave place to the *Missionary Herald*, he became editor of the latter, and by many essays and other contributions showed himself a most efficient advocate and organizer of Christian missions.

EVARTS, WILLIAM MAXWELL, LL.D., b. Boston, Feb. 6, 1818; son of Jeremiah. He graduated at Yale in 1837, and studied in the Harvard law school under Justice Story and Prof. Greenleaf; was admitted to the New York bar in 1841; deputy U. S. district attorney, 1849–53, during which period he became conspicuous in prosecuting persons engaged in filibustering expeditions to Cuba. In 1853, he was counsel for the state of New York in the Lemmon slave case. In the impeachment trial of President Johnson, he was the leading counsel for the defendant, and in 1872 he was counsel for the United States before the tribunal of arbitration at Geneva. He was president of the New York city bar association in 1880–1. Among many noted cases in which he has appeared are the Parrish will case; the will case of Mrs. Gardner, mother of the widow of President Tyler; as senior counsel for Henry Ward Beecher in the Tilton suit, and as advocate (on the republican side) before the electoral commission. He has made many public addresses, such as the eulogy on chief-justice Chase, the centennial oration at Philadelphia, at the unveiling of the statues of Webster and Seward in New York, and at the unveiling of Bartholdi's statue of Liberty. He was an early and active member of the republican party. In July, 1868, he was appointed attorney-general of the United States, and in Mar., 1877, became secretary of state, resigning in 1881, to resume the practice of his profession in New York. In 1885 he was elected to the United States senate, retiring at the expiration of his term in 1891.

EVE (Heb. *Chavvah*, i.e., the living), the name, according to the Hebrew narrative, of the wife of the first man, and so the mother of the human race. See ADAM and EVE.

EVE, PAUL FITZSIMMONS, M.D., b. Augusta, Ga., 1806; graduated at the University of Georgia, 1826; and at the medical school of the University of Pennsylvania, 1828. He studied in Europe for several years, and acted as surgeon in the Polish revolution of 1831, receiving in recognition of his services a cross of honor. He was professor of surgery in the Georgia Medical College (1832), in Louisville University (1849), in Nashville University (1850), in the Missouri Medical College (1868), and again in Nashville University in 1870. As a surgeon he was remarkable for his successful operations for stone. He died Nov. 3d, 1877.

EVECTION, a lunar inequality resulting from the combined effect of the irregularity of the motion of the perigee, and alternate increase and decrease of the eccentricity of the moon's orbit. See LUNAR THEORY.

EVELYN COLLEGE. See COLLEGIATE EDUCATION FOR WOMEN.

EVELYN, JOHN, a well-known writer of the 17th c., was b. Oct. 31, 1620, at Wotton, the seat of the Evelyn family, in Surrey. He was educated at the free school of Lewes,

and subsequently at Balliol college, Oxford. In 1640, he entered the middle temple, and in the following year, prompted by the ominous appearance of public affairs, and after having witnessed the trial of Strafford, he set out for the continent, returning, however, in the autumn of the same year. In 1642, upon offering his services to Charles I., he was accepted as a volunteer in prince Rupert's troop, but in 1643 he again went to the continent, where he mainly lived during the following eight years. After 1652, he settled in England, where he lived studiously and in private till the restoration, after which he was much employed by the government. On the organization of the royal society, he became one of the first members, and was an industrious contributor to its transactions. He succeeded, in 1699, to the family estate at Wotton, and there, after a long, studious, and highly useful life, he died 27th Feb., 1706.

His pen seems to have been constantly employed, and that upon a great variety of subjects. Art, architecture, gardening, commerce, etc., were all treated of by E., and in such a manner as to produce the most beneficial results on his own time. His principal works are *Sculptura, or the History and Art of Chalcography and Engraving on Copper*, 1662; *Silva, or a Discourse of Forest Trees, etc.*, 1664; and his *Memoirs* (first published in 1818). It is to the last of these works E. owes the celebrity he now enjoys. The *Memoirs* are written in the form of a diary, by one who had accustomed himself to habits of close observation, and continued during a period of about 70 years—and these the most dramatic in the recent history of England. They are of inestimable value. Sir Walter Scott said that "he had never seen a mine so rich." New editions were published in 1850, 1854, and 1870.

EVEMERUS, or **EUHEMERUS**, a Greek scholar of the latter part of the 4th c. A.D. He is noted chiefly for his *Sacred History*, founded professedly on archaic inscriptions which he had collected during his travels in various parts of Greece, and more especially on those observed on the temple of Jupiter Triphylanus, in the island of Panchæa. In this work, he introduced a new method of interpreting the popular myths, asserting that the gods who formed the chief objects of popular worship were mortals who, as heroes and conquerors, had earned a claim to the veneration of their subjects. Till the end of the last century, there were many who accepted this system of Evemerus, and the early Christians especially appealed to it as a confirmation of their belief that the ancient mythology was merely an aggregate of fables of human invention. Evemerus was a firm upholder of the Cyrenaic philosophy, and by many ancient writers he was regarded as an atheist, because of his dissent from the prevalent polytheism. Of his work only a few fragments remain in a Latin translation by Ennius. See **EUHEMERISM**.

EVENING PRIMROSE. See **ENOTHERA**.

EVENING SCHOOLS may be divided into two classes: 1. Those which, either in the form of lectures or lessons, carry further the education received at school; 2. Those which exist to supplement the defects of early training, or, it may be, to give the simplest rudiments of elementary instruction to adults who are under the disadvantage of being pupils for the first time in their lives. The former are found chiefly in connection with mechanics' institutes* (which are now very numerous in Great Britain, and might form one of the most important educational agencies we have), existing day schools, and congregational organizations; while the latter more frequently fall under the head of parochial missionary work, or are connected with factories. These latter constitute the class of E. S. which engage the largest share of interest in the present condition of England, and which present the greatest difficulties in working.

Considering the large proportion of the present adult population unable to read or write, the number of E. S. is miserably inadequate. But the necessity for their institution has not yet been sufficiently felt by the country, to lead to their taking a much more important place in the educational machinery of the nation than they have hitherto done. Her majesty's inspectors, the royal commissioners (1861), and the clergy of all denominations, strongly recommend their greater extension. "If the education of the country were in a good state," say the commissioners, "E. S. would be nearly universal, and would serve to compensate the scantiness of the instruction given in day schools, by giving more advanced instruction to an older class of scholars."

State Aid, and Voluntary and Paid Teachers.—Many educationists have come to the conclusion, that the hope of retaining children in school until they have obtained as much instruction as is requisite for their guidance in life is a vain one, and consequently look to E. S. as an indispensable part of a national system of education, and consider them entitled to look to the state for encouragement and support to an equal extent with day schools. Bishop Hinds was the first *publicly* to suggest that E. S. fairly come within the sphere of state action, in a letter to Mr. Senior, printed in 1839. The recent inquiries have brought out that the majority of those who frequent existing E. S. have never received any elementary instruction, or have forgotten what they once knew, and that a large proportion are either adults or adolescent young men and women. They attend for the purpose of learning to read, write, and cipher. Though in many instances, especially where no fee is charged, the irregularity and unpunctuality of the attendance are great, yet in the majority of cases there is an earnest desire on the part of the pupils

* The working-man's college in London, and the school of arts in Edinburgh, both belong to this class.

to benefit by the instruction they receive. It is a question of some national importance how far schools of this supplementary class should be left to the action of private philanthropy. It is also a question, to some extent implied in the other, whether the peculiarly delicate work required in E. S. is not more efficiently discharged by voluntary than by paid laborers.

1. As to the first question, it may be safely said, that all would desire to see those wholesome channels of benevolence which connect the poor and the rich free from government interference; but if, in our devotion to a theory, we neglect the work, it becomes the duty of the state to see to it, to the extent of encouragement at least, if not of direction. Since bishop Hinds' letter, to which we have referred above, the education committee of the privy council have recognized this duty, and have given aid to a small extent to all E. S. complying with certain conditions, and in connection with day schools. By the revised code recently issued by the privy council, E. S. of this class are allowed to claim from the parliamentary grant a considerable sum calculated on the average attendance. The schools must be taught by certificated masters, and lay persons are alone recognized. To all those schools frequented for the purpose of confirming or extending previous knowledge, the grants made under the code will be of great assistance, and enable them to secure the services of trained teachers; to those which are chiefly frequented by adults wholly ignorant of the simplest elements, and chiefly conducted by voluntary teachers, it will afford little or no advantage, because the conductors will not be able to claim so large a sum as would suffice to pay the salaries of certificated masters. Nor, perhaps, is it desirable to interfere with this particular class of E. S.; it is of more importance, so far as state aid is concerned, that the education of the primary school should be confirmed by the establishment of E. S. for *boys and girls*. There is active benevolence enough abroad to overtake the ignorance of the *adult* population, if properly stimulated by the various religious bodies.

The proposed new arrangements as to payment may also lead to the greater separation of such schools into schools for boys and girls above 13 and under 18, and schools for adults. It is found that boys and men, girls and women, do not work well together.

2. As to the second question: in those E. S. which are only a continuation of the day school, the same method will generally be found to suit as in the primary schools; and therefore it seems advisable that they should be conducted by paid certificated teachers, acting under managers (as in the case of ordinary day schools), and claiming grants from the privy council. Those schools, again, which are frequented by adults, who come to receive the elements of reading, writing, and arithmetic for the first time, require more delicate handling, and a greater consideration of individual character and wants than are requisite in a school attended by boys and girls. In such cases, voluntary effort under the influence of religious or merely philanthropic motives appears to be the best agency. The ignorance of method displayed by such teachers, and the irregular manner in which many of them hang to their work, are no doubt serious difficulties; but they may be overcome by the institution of diocesan or other unions, in imitation of the East Lancashire union of E. S. under the presidency of sir J. P. K. Shuttleworth, with each of which might be connected an organizing master, who should itinerate among the schools, giving the benefit of his superior knowledge of method.

Subjects and Method.—As to subjects to be taught, we have little to say to that class of E. S. which continue the work of the day school. It is to be presumed that practical instruction (and what else should be aimed at in such schools?) will embrace the elements of those sciences which bear most directly on life. We refer to social economy and the laws of health. E. S. of the humbler and more urgent sort will necessarily confine themselves to reading, writing, and arithmetic, inventing such methods of teaching those subjects as will most directly touch the intelligence and engage the interest. The short period of attendance requires that *much* be done rather than *many things*. Through a well-constructed course of reading-books (unfortunately, there is no reading series for adults worthy of mention), all the general culture and specific information attainable will best be given. If such reading-books do not furnish adequate information on social economy in its domestic and its wider social relations, and on the laws of health, they sadly misunderstand their position in educational literature. Instruction in writing and arithmetic should be given in such a way as will naturally connect itself with the lives and daily necessities of the learners. But this is not the place to treat of the subject of method.

History.—Although we have directed attention to the fact that Bishop Hinds was the first in Gr. Britain to advocate state recognition for E. S., he was by no means the first to feel the necessity that existed for them. The first school established exclusively for adults was at Bala, Merionethshire, in 1811, by the Rev. T. Charles. In 1812, a similar school was set on foot in Bristol by William Smith and Stephen Prout, a school which led to the establishment of the "Bristol institution for instructing adults to read the Holy Scriptures." In 1813, writing was included in the school programme; and in 1816, a society of the same kind was founded in London. In the course of a few years, 30 towns possessed similar schools. The first *evening* school proper for instructing boys and girls who had to work all day for a livelihood, was founded in 1806 at Bristol, by the "benevolent evening schools' society."

In other countries of Europe, E. S. where they exist, have mainly in view the continuance of the education already received in primary schools. In France, however, the wants of untaught adults have been provided for by the establishment by law of E. S. suited to them. In all the states of Germany, provision is made more or less in the country districts, and always in the large towns, for continuing the instruction given in the primary schools. Schools for those who wish to learn reading and writing for the first time seem scarcely to exist, probably because they are not needed. The schools which do exist have a greater affinity to our mechanics' institutes than to any other kind of institution in this country. The instruction is given on Sundays and holidays, and in many places also on one or two evenings in the week. But Sunday instruction seems alone to have been originally contemplated. The subjects taught are the ordinary branches, with geography, free-hand and geometrical drawing, geometry, and in some cases the elements of natural science and the laws of health. These institutions are supported by the funds of the commune or district; in some cases supplemented by the state. See EDUCATION, COMMON SCHOOLS, MANUAL TRAINING.

EVERDINGEN, ALLART VON, 1621-75; a Dutch painter of coast and inland scenery, particularly of Norway, where he suffered shipwreck. His favorite theme was a fall in a glen, with mournful fringes of pines interspersed with birch, and log huts at the base of rocks and craggy slopes. The water in his scenes tumbles over the foreground so as to entitle the painter to the name of "inventor of cascades."

EVEREST, Sir GEORGE, 1790-1866; b. Wales. He was employed in various engineering works in India, was assistant to the chief in the trigonometrical survey of that country, and on the chief's death became his successor. Afterwards he was surveyor-general of India. He gave his name to the mountain named in the next article.

EVEREST, MOUNT, in the Himalaya range in Nepaul, Asia; the highest mountain peak on the earth, so far as known. A careful measurement in 1856 made its height 29,002 ft. above tide, or within 38 ft. of $5\frac{1}{2}$ English miles.

EVERETT, ALEXANDER HILL, an American diplomatist and author, was b. at Boston, Mass., 19th Mar., 1792, and entered Harvard college in 1802. In 1806, although the youngest of the *alumni*, he graduated with the highest honors. After practicing for some time as a lawyer, he was appointed U. S. ambassador at the Hague in 1818; and went in the same capacity to Spain in 1825. Four years afterwards, he returned to the United States, where he became proprietor and editor of *The North American Review* (1830-35), and also occupied a seat in the legislature of Massachusetts. In the winter of 1840, he resided, as a confidential agent of the U. S. government, in the island of Cuba. He sailed for China as minister-plenipotentiary for that empire in 1845, and died at Canton, June 23, 1847. E. was a man of great versatility of talent and of extensive erudition. Politics and belles-lettres, political economy and poetry, statistics and æsthetics, alternately engaged his thoughts and pen. His writings are—*Europe, or a General Survey of the Political Situation of the Principal Powers*, etc. (London and Boston, 1822); *New Ideas on Population*, etc. (London and Boston, 1822); *America, or a General Survey of the Political Situation of the several Powers of the Western Continent*, etc. (Phila. 1827), in which he labors to show that Russia and the United States must in the long-run share the continent between them; *Critical and Miscellaneous Essays* (two series, Boston, 1845 and 1847). These are on a vast variety of subjects, and are probably the most interesting productions of his pen. E. also published a volume of poems in 1845.

EVERETT, EDWARD, LL.D., was born in Dorchester, Mass., April 11, 1794; d. Boston, Jan. 15, 1865; an American statesman, orator, and scholar, son of Rev. Oliver Everett. He was at one time a pupil in a Boston school, of which Daniel Webster, in the absence of his brother Ezekiel, was the teacher. In 1811, when only 17 years of age, he graduated at Harvard with the highest honors of his class. While an undergraduate he had the principal charge of a students' paper called the *Harvard Lyceum*. In 1812, he was appointed tutor at Harvard, and while thus employed, found time to prepare himself for the ministry. He was ordained pastor of the Brattle street church (Unitarian) in Boston, Feb. 19, 1814. As a preacher his career was brilliant, though brief. He resigned his pulpit at the end of 13 months, when not quite 21 years of age, having accepted the Eliot professorship of Greek literature at Harvard. To fit himself more completely for his new position, he went to Europe and studied for two years in the university of Göttingen, receiving the degree of PH.D. He then traveled extensively in England and upon the continent, making special visits to Athens and Constantinople. In England he made the acquaintance of the most eminent men of that day, Scott, Jeffrey, Romilly, and Davy. His range of study during his residence abroad was wide, embracing not only the branches included in his professorship, but a close examination of civil and political law, and of the European systems of government. Upon his return in 1819, he entered upon the duties of his professorship, delivering at the outset a course of lectures on ancient Greece, its architecture and ruins, which he afterwards repeated in Boston. During the period of his professorship, which continued till 1825, he became the editor of the *North American Review*, to which he contributed a great number of articles. In

1824, in the presence of Gen. Lafayette, he delivered the Phi Beta Kappa oration at Harvard, winning new fame by his thoughtful and eloquent presentation of the theme, "Circumstances Favorable to the Progress of Literature in America." On the 22d of Dec. of the same year, he delivered an oration at Plymouth that kindled for him a wide popular enthusiasm. In the same year (1824) he was elected to congress from the Cambridge district. He was subsequently re-elected for four successive terms, making his whole period of service in that body 10 years. During this whole term he was a member of the committee on foreign relations, and in the 20th congress its chairman. He also served on the library committee, and generally on that for public buildings. He was also a member of some important select committees. His familiarity with the science of government and with the public questions of the time, united with his high literary qualifications, and his acknowledged power as a speaker, fitted him for great usefulness in committees and upon the floor. Some utterances are on record which may be taken as early indications of his subsequent position on the question of slavery. On the 9th of Mar., 1826, he brought upon himself the rebuke of Churchill C. Cambreling, member from New York, but a native of South Carolina, for these words: "The great relation of servitude, in some form or other, with greater or less departure from the theoretic equality of men, is inseparable from our nature. Domestic slavery is not, in my judgment, to be set down as an immoral and irreligious relation. It is a condition of life as well as any other to be justified by morality, religion, and international law." "Sir, I am no soldier. My habits and education are very unmillitary; but there is no cause in which I would sooner buckle a knapsack on my back, and put a musket on my shoulder, than that of putting down a servile insurrection at the south." In 1835, he was elected governor of Massachusetts, holding the office by annual re-election until 1840, when he was defeated by a single vote. In his first message to the legislature, Jan., 1836, he took occasion to refer in deprecatory terms to the anti-slavery excitement of that day, and, alluding to the anti-slavery papers, which were almost universally denounced as "incendiary," he said: "Whatever by direct and necessary operation is calculated to excite an insurrection among the slaves has been held by highly respectable legal authority an offense against the peace of the commonwealth, which may be prosecuted as a misdemeanor at common law." As the governor was known to have at that moment in his official possession, to be communicated to the legislature, the official demands of several of the southern states for the enactment by northern legislatures of laws to suppress the anti-slavery societies and journals, this portion of his message created much excitement in the state, and intense alarm in the anti-slavery party. Remonstrances in large numbers, against the adoption of the proposed legislation, were sent to the legislature, and the remonstrants were accorded a public hearing before a special committee. After a severe struggle, the contemplated restriction of the freedom of the press was averted, and no effort was ever made to enforce the governor's suggestion in regard to proceedings under the common law for the same object. While in congress, Mr. E. was a constant contributor to the *North American Review*, and among his papers published therein, was one in which he very ably and successfully controverted the South Carolina doctrine of nullification. In 1841, he was appointed by President Harrison minister plenipotentiary of the United States to Great Britain. The news of this appointment reached him in Italy, whither he had gone for the purpose of engaging in historical work. He hastened to obey the call of his country, and entered at once upon the discharge of his official duties. The relations of this country with England at that time involved our minister in very grave responsibilities, which Mr. E. discharged in a manner creditable alike to the country and to himself. Returning home in 1845, he reluctantly accepted the presidency of Harvard university, giving the next three years to strenuous labor in behalf of his alma mater. After his resignation, he established himself in Boston with the purpose of entering upon literary tasks long postponed. He prepared a collected edition of his own orations and speeches, which appeared in 1850. He also edited a new edition of the works of Webster, at his special request, and prepared a memoir of the author. From such congenial labors he was next summoned to fill the place of secretary of state in the cabinet of President Fillmore, made vacant by Mr. Webster's death. He held this position only four months, retiring at the close of President Fillmore's administration; but during this time several important questions of state received his careful attention. Before leaving the department of state he was elected to the U. S. senate. Feb. 8, 1854, he made a powerful speech in the senate in opposition to the abrogation of the Missouri compromise of 1820, which prohibited slavery in all the territories ceded by France to the United States n. of the line of 36° 30'. The object of this abrogation was to open to slavery the territories of Kansas and Nebraska. Mr. Everett having been a conspicuous supporter of Webster and the compromises of 1850, was in a position to make his influence felt upon this new issue, but the measure was carried in spite of his eloquent remonstrances. His health failing, he resigned his seat in the senate in May and retired to private life. After recovering his strength, he devoted himself for several years to the work of procuring funds wherewith to purchase Mount Vernon, the home and burial-place of Washington, to be held in perpetuity as a place of resort and pilgrimage. He prepared an eloquent discourse upon the life and character of Washington, which he delivered nearly one hundred and fifty times in different places in the country, devoting the proceeds to this

object. He also engaged to contribute an article weekly for one year to the *New York Ledger* for \$10,000, to be paid by the proprietor to the Mount Vernon fund. The articles were afterwards republished in a volume entitled *Mount Vernon Papers*. Giving his time gratuitously and paying his own traveling expenses, he raised over \$100,000 in all for the Mount Vernon fund. He subsequently, by similar methods, obtained considerable sums for several public charities. In 1860, he was nominated for vice-president of the United States, with John Bell of Tennessee for president, by a small remnant of the whig party, which had fallen to pieces under the growing anti-slavery sentiment of that period. The ticket received 590,631 votes from a total of 4,662,170. When the civil war broke out in 1861, he took his stand promptly among those who determined to maintain the union at every hazard. His patriotic addresses at this crisis were of great service, influencing as they did a large body of conservative men, who, like himself, had done all in their power to discourage and resist anti-slavery agitation. His oration at the consecration of the national cemetery at Gettysburg, Penn., Nov. 15, 1863, was a production creditable alike to his patriotism and his high literary ability. In the great crisis of 1864, when Lincoln was re-elected, Mr. Everett's name headed the list of presidential electors of Massachusetts, and his vote for Lincoln was the last act in his political career. Jan. 9, 1865, he spoke in Faneuil Hall in behalf of the needy and suffering citizens of Savannah, and on the following Sunday, the 15th, he died. He received the highest literary honors from the great English universities as well as from his alma mater. He was a corresponding member of the institute of France, and enjoyed the friendship of the greatest men of his time in Europe and America. A statue of him by Ball stands in the Boston public library, and another, by Story, in the public garden.

EVERETT, a city in Middlesex co., Mass., 3 m. n. of Boston; a part of the town of Malden till 1870; incorporated as a city in 1893. It is on the Boston and Maine railroad and has electric railroad connection with Boston, Melrose, Wakefield, Lowell, Lynn, and Salem. It contains several churches, public schools, a high-school, public library, savings bank, weekly newspapers, and a young ladies' seminary. The city contains a number of manufactories, the principal articles being chemicals, bicycles, baby carriages, phosphates, wheels, rope, foundry products, roofing materials, furniture, and varnish. Pop. '90, 11,068.

EVERETT, WILLIAM, b. 1839; youngest son of Edward Everett, graduated at Harvard college, 1859, and at Trinity college, Cambridge, England, in 1863; studied law; was assistant professor of Latin in Harvard college, 1863-81, and in 1882 was made principal of the Adams academy, Quincy, Mass. He published *On the Cam*, lectures (1865) giving his experience at Cambridge; *Changing Base* (1868); *Hesione*, or *Europe Unchained*, poem (1869); *Double Play* (1870); *School Sermons* (1881), and some other books for boys. He was elected a member of Congress as a democrat in 1892, and declined a renomination.

EVERGLADES, a peculiar swampy region in s. Florida, in Dade and Monroe cos., about 160 m. long by 60 m. wide, s. of lake Okeechobee. The E. consist of a vast number of small and low islands, separated by channels in which the water is usually shallow. The islands are covered with dense thickets of pines, palmettoes, vines, and tropical shrubs, and the soil is very fertile. The water in the channels is concealed by tall grass. The country is almost entirely wild, and abounds in small game. A few Seminole Indians still inhabit the region. During the Seminole War in 1835, these Indians ambushed and destroyed in the Everglades a body of United States troops under Major Dade; and were not driven from these swamps until after a struggle which cost the Government fully \$10,000,000, and 1500 men.

EVER GREEN ISLE. See IRELAND.

EVERGREENS are those trees and shrubs of which the leaves do not fall off in autumn, but retain their freshness and verdure throughout the winter, and perform their functions during more than one season. Evergreen leaves are generally of thicker and firmer texture than the leaves of deciduous trees and shrubs. They have also fewer pores or *stomata* (q.v.), and these confined to their under surface. Evergreen leaves are sometimes very small, as in firs and heaths; sometimes pretty large, as in rhododendrons, laurels, magnolias, etc. E., both trees and shrubs, have always been much sought after by the landscape gardener, and for purposes of ornament and shelter. Some orders of plants consist exclusively, or nearly so, of E., whilst in others they exist only as exceptional species. Most of the *coniferae* are E., and the somber green of pines, firs, cypresses, etc., is a prevalent characteristic of northern scenery both in summer and winter; whilst the undiminished thickness of the foliage affords winter shelter to animals which could not so well exist in forests composed merely of deciduous trees. Holly and ivy are amongst the finest of them; the box, privet, and different kinds of bay and laurel, rhododendron, phyllirea, myrtle, etc., are also familiar to every one. As instances of genera in which some species are evergreen and others deciduous, may be mentioned barberry and cytisus. Many fine new ornamental E. have recently been introduced. As suitable for imparting a lively appearance, boughs of E. are largely employed in America to decorate the walls of public places of assemblage, triumphal arches, etc., on festive occasions, and the various species of lycopodium or *club moss* are extensively wrought into wreaths and garlands for similar purposes, especially at Christmas time. Among the many foreign coniferous evergreen

trees planted in gardens in the United States are the silver spruce, *abies argentea*; the Norway spruce, *abies excelsa*; the narrow-leaved spruce, *abies tenuifolia*; the mountain yew, *cephalotaxus montana*; the Japan weeping cypress, *cryptomeria Japonica*; the English juniper, *juniperus communis*; the Japan juniper, *juniperus Japonica*; the European silver fir, *picea pectinata*; the Scotch pine, *pinus sylvestris*; the English yew, *taxus vaccata*; the weeping yew, *taxus Dovastonii pendula*; the Japan arbor vitæ, *thuya Japonica*; and the Chinese arbor vitæ, *thuya Orientalis*.

The more plentiful and important of evergreen trees and plants native in the United States are given in the following list :

| | |
|---------------------------------|---------------------------------|
| White Spruce..... | <i>Abies alba.</i> |
| Hemlock..... | <i>Abies Canadensis.</i> |
| California Spruce..... | <i>Abies amabilis.</i> |
| Douglass Spruce..... | <i>Abies Douglassii.</i> |
| Mexican Spruce..... | <i>Abies Mexicana.</i> |
| Black Spruce..... | <i>Abies nigra.</i> |
| Red Spruce..... | <i>Abies rubra.</i> |
| Sabine's California Spruce..... | <i>Abies Sabini.</i> |
| California White Cedar..... | <i>Libocedrus decurrens.</i> |
| White Cedar..... | <i>Cupressus thyoides.</i> |
| Great Coned Cypress..... | <i>Cupressus macrocarpa.</i> |
| Mexican Cypress..... | <i>Cupressus Mexicana.</i> |
| Red Cedar..... | <i>Juniperus Virginiana.</i> |
| Great Flowered Magnolia..... | <i>Magnolia grandiflora.</i> |
| Balsam Fir..... | <i>Abies balsamea.</i> |
| California Noble Fir..... | <i>Abies nobilis.</i> |
| White Pine..... | <i>Pinus strobus.</i> |
| Yellow Pine..... | <i>Pinus mitis.</i> |
| California Yellow Pine..... | <i>Pinus brachypterus.</i> |
| California Nut Pine..... | <i>Pinus edulis.</i> |
| Jersey Pine..... | <i>Pinus inops.</i> |
| Scrub Pine..... | <i>Pinus Banksiana.</i> |
| Pitch Pine..... | <i>Pinus rigida.</i> |
| Long-leaved Pine..... | <i>Pinus australis.</i> |

| Spruce Pine..... | <i>Pinus glabra.</i> |
| Mountain Pine..... | <i>Pinus pungens.</i> |
| Loblolly Pine..... | <i>Pinus taeda.</i> |
| Lambert's Californian..... | <i>Pinus Lambertiana.</i> |
| Red Pine..... | <i>Pinus resinosa.</i> |
| Bald Cypress..... | <i>Taxodium distichum.</i> |
| American Yew..... | <i>Taxus baccata Canadensis</i> |
| Florida Yew..... | <i>Taxus Floridana.</i> |
| American Arbor Vitæ..... | <i>Thuya occidentalis.</i> |
| Giant Arbor Vitæ..... | <i>Thuya gigantea.</i> |
| California Torreya..... | <i>Torreya Californica.</i> |
| Great California tree..... | <i>Sequoia gigantea.</i> |
| Redwood..... | <i>Sequoia sempervirens.</i> |

EVERLASTING FLOWER, the popular name of certain plants, the flowers of which suffer little change of appearance in drying, and may be kept for years without much diminution of beauty. They are plants of the order *compositæ*, having their flowers (heads of flowers) surrounded with an involucre; the scales of which resemble the petals of a corolla, but are rigid, membranous, and contain little moisture. Some species of cudweed (q.v.) (*gnaphalium*) are often called E. F., and the other plants which bear the name belong to nearly allied genera, but particularly to the genus *helichrysum*, which contains a great number of species, mostly natives of Africa. *H. arenarium* is frequent on dry sandy soils in many parts of Europe and the central latitudes of Asia. It is covered with a gray felted down, and has yellow flowers, which, when rubbed, emit a faint aromatic odor. The French call them *immortelles*, and in France they are often woven into circular wreaths, and placed beside recent graves, as emblems of immortality.

EVERSLEY, CHARLES SHAW LEFEVRE, Viscount, ex-speaker of the house of commons, was b. in 1794, and descended maternally from the Lefevres who went to England from Rouen on the revocation of the edict of Nantes. He was educated at Winchester and Trinity college, Cambridge, called to the bar at Lincoln's Inn in 1819, entered parliament in 1830, as a member for Downton, and represented Hants from 1831 to 1857. In 1839, he was chosen speaker of the house of commons; and re-elected in the parliaments of 1841, 1847, and 1852. He retired from the office in 1857, with a peerage and a pension of £4,000 a year. During the eighteen years of his speakership, he suggested and carried out many improvements in the forms and procedure of the lower house, tending to the dispatch of business. Tall, and dignified in person, affable and accessible to the younger members, and profoundly versed in the laws of debate and practice.

of the house, he was admirably qualified, by nature and training, to be "first commoner of England." He d. in 1888.

EVESHAM, originally **EOVESHAM**, a municipal and parliamentary borough in the s.e. of Worcestershire, on the right bank of the navigable Avon, 15 m. s.e. of Worcester. It lies in a beautiful and fertile vale, and has for many years been noted for market-gardening. Pop. 91, 5836. Till 1885, E. sent one member to Parliament. An abbey was founded here about 700. It was the scene of Simon de Montfort's defeat by the royal troops in 1265, terminating the Barons' War.

EVICTION, in the law of Scotland, is the dispossessing one of property, whether in land or movables, in virtue of a preferable title in the person of him by whom the eviction is made. The same expression is used in England as to property in land; but where the tenant is merely deprived of possession, it is called ouster.

EVIDENCE, LEGAL. Evidence is either parol or written, the former consisting of the statements of witnesses appearing personally in court, and which statements must be attested by an oath or solemn declaration; the latter consisting of records, deeds, and other writings.

A distinction—popular rather than legal—is commonly drawn between *direct* and *circumstantial* evidence. Evidence is said to be direct when the proof depends on the testimony of persons who swear to the fact in dispute as matter of personal knowledge; when the witnesses only swear to other facts from which the fact at issue may be inferred, the evidence is called circumstantial. The latter kind of evidence is usually regarded as inferior in value to direct. Yet it is sometimes held that circumstantial evidence may be the more trustworthy; for either the witnesses may be unaccountably mistaken, or may have designed to deceive, whereas, as Paley said, "circumstances cannot lie."

The tendency, both in England and Scotland, of late years, has been to abolish all restrictions on the admissibility of witnesses, and to bring the rule practically to what Blackstone stated it to be in theory, viz., "all witnesses that have the use of their reason are to be received and examined." The ground on which witnesses were formerly excluded was untrustworthiness, arising either from the character of the witnesses or their interest in the suit. Under the former head fell those who were legally infamous (q.v.); whilst the latter included, first, the party to the suit himself, and then all who were connected with him by the ties of family, or even of business, in any appreciable degree. Gradually, however, it came to be seen that, though witnesses subject to these objections were less valuable than others to the party adducing them, it by no means followed that their testimony was of no value at all, and that the safer course in all cases was to examine them, and then to allow their testimony to be invalidated by proof of their interest in the cause direct or indirect, or of their having been convicted of such crimes as to render it unlikely that they should speak the truth. The objections have thus become objections not to the admissibility or competency, but to the credibility of witnesses. The first of the very important statutes by which these changes were effected was 9 Geo. IV. c. 32, which permitted Quakers and Moravians to substitute a solemn affirmation for an oath; admitted the party whose name had been forged as a witness in prosecutions for forgery; and provided that no misdemeanor (except perjury) shall render a party an incompetent witness after he has undergone the punishment. Then came the Scotch act 3 and 4 Vict. c. 59, afterwards referred to, and the English act 6 and 7 Vict. c. 85, which provided that no person offered as a witness shall hereafter be excluded, by reason of incapacity from crime or interest, from giving evidence either in person or by deposition on any issue or inquiry civil or criminal, but shall be admitted notwithstanding he may have an interest in the matter in question, or in the event of the trial or proceeding, and notwithstanding that he may have been previously convicted of any crime or offense. The same principle was extended by 14 and 15 Vict. c. 99 to the parties to a cause, who are not only competent, but compellable to give evidence on behalf of either or any of the parties—subject only to exception where the question tends to criminate the person examined, or where one (now altered) sued for breach of promise of marriage, or any action or proceeding instituted in consequence of adultery. By 16 and 17 Vict. c. 83, the former statute, 14 and 15 Vict. c. 99, was amended to the effect that the husband or wife of the party shall be in the same position with the party himself, subject only to these exceptions—first, that the husband or wife cannot give evidence for or against each other in criminal proceedings (but now they may in suits for adultery), and that they cannot be compelled to disclose matters which they have learned by communications from each other during the marriage. The statutes by which the corresponding changes were effected in Scotland were 3 and 4 Vict. c. 59, 15 and 16 Vict. c. 27, and 16 and 17 Vict. c. 20.

The oath (q.v.) to "speak the truth, the whole truth, and nothing but the truth," is administered to witnesses in England on the New Testament; in Scotland, holding up the right hand. Quakers and all conscientious persons, of whatever religious denomination, who object to the use of an oath, as formerly observed, make a solemn affirmation (q.v.); and persons who are foreigners are sworn, or otherwise bound over to speak the truth, by such forms as are conceived to be appropriate to their respective creeds. The test of the amount of religious belief which will suffice to render a witness admissible, has been generally considered to be a belief in future rewards and punishments:

but there is no decision which fixes the point, and in England, belief in a God, and that divine punishment will be the certain consequence of perjury here or hereafter, is enough. To obviate captious objections, the sacredness of oaths was secured by 1 and 2 Vict. c. 105, which provides that all persons shall be bound by the oath administered in the form and with such ceremonies as such persons shall declare to be binding.

It is a general rule of the law of evidence, that a witness is not bound to criminate himself, and he may consequently decline to answer any question that tends to expose him to punishment as a criminal, or to penal liability, or to forfeiture of any kind. If the effect of the question be merely to establish that he owes a debt, or is otherwise subject to a civil suit, the exception will not hold, and he will be bound to answer it (46 Geo. III. c. 37). The rule in England is, that a counsel, attorney, or solicitor is not bound, or even entitled, to divulge the secrets of the cause with which he has been intrusted; and the recent Scottish act 15 and 16 Vict. c. 27, s. 1, preserves the same exception with reference to agents who shall at the time when so adduced be acting in that capacity. Neither can official persons be called upon to disclose matters of state, the publication of which might be prejudicial to the community. All other professional persons, however—lawyers not engaged in the cause, physicians, surgeons, and divines, must divulge all secrets relevant to the issue with which they have become acquainted, even in the strictest professional confidence. See CONFESSIOAL. Neither will a servant nor private friend be allowed to withhold a relevant act, though of the most delicate nature.

One witness in England is sufficient in law, unless in the case of treason, if juries believe him, and in long chains of evidence it is often impossible that more than one witness should be adduced to make out some of the links of it. In general, however, there will be some fact or circumstance which will act as a supplementary adminicle, if the testimony be reliable; and it is this fact which has rendered the practical effect of the opposite rule, which demands two witnesses, in Scotland, not very different. The want of a second witness is usually supplied by a witness to circumstances which are corroborative of the evidence of the first; and where the one witness is not so corroborated in England, he will rarely be believed. It is a rule that none but the best evidence shall be adduced, which means that secondary shall not be substituted for primary evidence where the latter is accessible; a rule founded on the presumption that such a substitution is probably prompted by a sinister motive. This rule applies to written as well as oral testimony, and excludes copies of documents, just as it excludes the "hearsay" of witnesses. The best works on evidence in English are Taylor (English), Greenleaf (American), and Dickson (Scotch).

Evidence, in American law, embraces all statements which a court permits or requires to be made by witnesses in relation to matters of fact pertaining to the case on trial, and all documents produced for the inspection of the court. The former is distinguished as *parol*, the latter as *written evidence*. Again, evidence is either *direct* or *circumstantial*. When a witness testifies to a fact in issue from his own personal knowledge, his evidence is *direct*; when he swears to other facts, from which the existence of the fact at issue is inferred, it is *circumstantial*. Generally *direct evidence* has more force than *circumstantial*, though the latter is sometimes of such weight as to carry conviction to a court or jury. Both are to be taken with some allowance for possible mistake or falsehood on the part of the witness. Evidence must be relevant to the issue, though it may embrace incidents in themselves irrelevant, but which are among the necessary surroundings of the fact to be proved. The contents of a document must be proved by the document itself if it be accessible; if not, then by a certified copy, or by oral evidence; the law requiring the "best evidence" procurable in each case. When a contract has been reduced to writing, *parol evidence* cannot be admitted to prove its contents; still less can any variations of its terms be thus proved. Courts presume, until the contrary is proved, that a document was executed on the day of its date. Alterations and interlineations in a deed are presumed to have been made before execution, but in respect to wills the rule is reversed. When the law requires an instrument, e.g., a will, to be attested, it cannot be used in evidence unless one attesting witness be called to prove its execution if such a witness be alive and capable of giving evidence. If there be no such witness, then the signature of at least one attesting witness, and of the person executing the deed, must be proved to be in their respective hand-writings. A will thirty years old is held to prove itself; that is, there is a presumption in favor of its validity. The burden of proof lies on the person who asserts the affirmative. A presumption on the part of a court can be set aside only by evidence, and the burden of proof rests upon the party making denial. In criminal cases—in trials for murder, for instance—malice is presumed and requires to be rebutted by evidence. A person who has not been heard of for seven years, unless the circumstances are such as to account otherwise for his absence, is presumed in law to be dead. His wife may marry again without liability to punishment for bigamy. The effect of presumption is to establish against a party a conclusion which stands until he disproves it. In many states uninterrupted, undisputed possession for 20 years is held to establish a title to real estate. In some states a shorter period is sufficient. By the common law, if a wife commits a felony, other than murder or treason, in the presence of her husband, she is not criminally liable, it being assumed that she was under coercion. This rule is greatly restricted in practice in the United States. It is a rule of law, to which, how-

ever, there are some qualifications, that a witness cannot testify to what he has heard another say, but to only what he himself knows. One of the exceptions to this rule is that the dying declarations of a murdered person as to the causes of his death and the person who committed the murder may be given in evidence by one who heard them. If a witness testify in a trial, his evidence may be proved in a subsequent trial. When doubts arise respecting the boundaries of land, or the pedigree of persons, and the question is material to determine the issue before the court, traditional evidence—in other words, declarations made long ago by persons supposed to have had knowledge of the subject—is sometimes admitted. The ordinary witness is confined to statements of fact; he cannot give an opinion, or state the inferences he draws from the facts within his knowledge. An “expert”—one skilled in some art or profession—is allowed and even required to give opinions as to the significance of facts whose meaning is not fully understood by a court or jury; e.g., a chemist may testify as to the effects of certain poisons upon the human system, or a surgeon may say whether in his opinion there has been malpractice in treating a wound. For reasons of public policy, the confidential communications between an attorney and client and between a husband and wife are excluded. “Secrets of state” and the deliberation of judges and juries are exempt from judicial investigation. A witness within the jurisdiction of the court is required to attend in person; if he be beyond the jurisdiction his testimony is taken by commission. Formerly parties to an action and others interested therein were not allowed to be witnesses, but they are now generally admitted, it being assumed that courts and juries will give due weight to the temptation which such witnesses may be under to swerve from the truth in their own interest. Persons of a defective understanding, or who are supposed to be insensible to the obligations of an oath, are held to be incompetent as witnesses. Persons convicted of an infamous crime are generally excluded. The tendency of law at present, however, is to widen the range of evidence as far as possible, and to regard many of the former grounds of exclusion as concerning not the admissibility but only the credibility of a witness. The party calling a witness is not allowed to ask him “leading questions”—i.e., questions which suggest their answers. The other party on cross-examination is not bound by this rule. A witness is not required to answer questions, when in doing so he must criminate himself. A witness may be impeached by proving that his reputation for truth and veracity is bad. See AFFIRMATION; DEED; DYING DECLARATION; FRIENDS; HEARSAY EVIDENCE; JURY; JURY TRIAL; OATH; PERJURY; SUBORNATION OF PERJURY; SUBPOENA; WITNESS.

EVIDENCES OF CHRISTIANITY. Christianity is the religion growing out of a divine revelation, the giving of which, in successive stages, extended from a remote period in the past to about one hundred years after the birth of Jesus Christ. From the beginning of the revelation to the present time it has been engaged in severe conflicts with the mightiest forces, and with whatever immediate outward result, it has maintained its hold on the human mind and has advanced in power. Thus the conflicts themselves become important factors in the strength of the evidences by which the authority of the revelation is upheld. 1. Moses, as a bearer of a part of the revelation, was brought into conflict with the Egyptians and inflicted on them, instrumentally, without human help, judgments and sufferings, the result of which was the deliverance of the Israelites from bondage, and the memorial of which is the Passover, instituted at the time and observed to this day by the Jews scattered over the world. 2. Moses came also into conflict with the barrenness of the wilderness, in providing for the sustenance of the Israelites, and with their turbulence and rebellion during their sojourn and wanderings there. The memorials of these conflicts are the wilderness itself, the law given there, and the Pentateuch written there. 3. Having traversed the wilderness, Moses, Joshua, and Israel were involved in a conflict with the nations of Canaan, on both sides of the river Jordan, the result of which was the conquest of the land; and the memorial of it is the land itself, illustrated by the book of Joshua, which (as has been said) bears a relation to Palestine as conquered by the Israelites, similar to that which doomsday book bears to England as conquered by the Normans. 4. Passing by minor conflicts between the Jews and the nations around them, we take notice of the great expedition of Sennacherib, king of Assyria, against them, and of its overwhelming defeat; to both which events the harmonious witnesses are the written records of the Jews and the sculptured records of Sennacherib. 5. Nebuchadnezzar, king of Babylon, desolated the land of Canaan, destroyed Jerusalem, burned the temple, and carried the Jews captive. The result of this judgment was their deliverance from idolatry, and the memorial of it is the book of Daniel with its splendid prophecies. 6. Cyrus, the conqueror of Babylon, might also have overwhelmed the Jews, but having been shown the prophecy of Isaiah, written 150 years before, in which he was mentioned by name and his success foretold, his spirit was stirred up to restore them to their own land. The memorials of the restoration were the temple rebuilt at Jerusalem and the synagogues erected throughout the land. 7. Alexander, in his rapid career of conquest, appeared before Jerusalem in anger against the Jews because they placed obstacles in his way. But when he was shown the prophecies of Daniel concerning the king of Grecia who was to conquer Persia, his anger giving way to joy, he treated the Jews kindly and placed many of them in the new cities that he built. Memorials of his change of feel-

ing towards them were furnished by Jewish synagogues built in the Greek cities and the Jewish Scriptures translated into the Greek tongue. 8. Antiochus the Great, one of Alexander's successors, seized Jerusalem and desecrated the temple by offering heathen sacrifices therein. His course awakened the zeal of the Jews and imparted new life and purity to their religion. A memorial of this reformation was furnished by the restoration of royal government to the Jews. 9. The Romans next obtained entrance into Jerusalem and established their power over the land. For a time they gave regal and vice-regal authority to Herod and his successors. Afterwards they made Judea a province and continued to hold it until, on the revolt of the Jews, they destroyed the city and the temple, and sold the inhabitants as slaves. In the midst of this Roman domination the crowning event of human history occurred—THE ADVENT OF JESUS CHRIST THE SON OF GOD; and the still-enduring memorials of it are Jerusalem trodden down by the Gentiles and the going forth out of it of Christianity, strictly so called, unaided by physical power, to gain possession of the world. 10. Its first conflict, in this form, was sustained by Jesus himself against the chief forces of the Jews among whom he came. His visible power consisted in a holy and unselfish life, in words of instruction surpassing all that men have ever spoken, and in beneficent works transcending all that men have ever wrought. The first result of this conflict was, apparently, his defeat by the Jews, for, aided by the Romans, they accomplished the death of Jesus and his burial in a sealed and guarded tomb. But the conflict was renewed by his followers, who offered themselves as witnesses of his resurrection and produced conviction in the minds of thousands of Jews, while also they aroused hostility in the hearts of many others. As the preaching of "Jesus and the resurrection" spread into other cities and lands, the conflict with Jews was continued, producing, as before, conviction in many minds and also hostility in many hearts. And to this day, Christianity and the Jews are arrayed against each other in many lands. 11. Its next conflict was with heathenism in union with the state. Proclaimed, almost immediately, as a gospel for the nations, it was opposed by the adherents of all idolatrous religions rallying against it as a common enemy, and by the governing classes, whose jurisdiction in religious matters (as they thought) it usurped. Yet it prevailed from city to city and from land to land. Heathen temples were almost deserted, and the fires of sacrifice on their altars went out. Trophies of the victory were furnished by the acts and writings of the apostles, by the planting and growth of churches, the joyful death of martyrs, the courage of confessors, and the argumentative defenses of learned men. If at the moment of triumph, in the council of Nicæa, the presence of the emperor Constantine—assuming, in some sense, to be the head of the assembly—was a fatal mistake, introduced from the heathenism which he had as yet scarcely left, let it not be forgotten that many of the bishops who rose to receive him were marked with bodily mutilations or scars, the tokens of their fidelity to Christ. 12. The next conflict of Christianity was with philosophy. While it contended only with Jewish and idolatrous rites, philosophers treated it with contempt and easily remained ignorant concerning it. But in its advance it awakened the hostility of Celsus, Porphyry, and others, who attacked it as false and mischievous; and, on the other hand, Justin Martyr, its first great defender among uninspired men, wore a philosopher's robe. From this point forward Christianity continued to be opposed by many in the ranks of philosophers and to be corrupted by the admixture with it of the philosophic opinions prevalent around it. 13. Christianity contended, also, with barbarism rude and strong. In the ages that followed the inroad of the northern tribes on Rome this religion was the only power that held them in check, tempering their fierceness and finally subduing them to the obedience of faith. Yet here also, as in its contests with Judaism, paganism, and philosophy, it was itself corrupted by admixture with the opinions and habits of those who received it. 14. Its next great conflict was with Mohammedanism. The Saracens were overrunning Christendom with the sword and the Koran from the east and south, but in the west the barbarians who had become Christians broke their power and poured the forces of Europe upon the Holy Land. And from those times to the present the "eastern question," in some form, has arrayed Christian Europe against Mohammedan rule. 15. The next great conflict was in Christendom itself. The corruptions which had been introduced from the worldly power of Rome, from heathen idolatries, philosophic opinions, and barbarian superstitions, accumulated and grew until Christianity became, in many respects, a baptized heathenism. But from itself, through the teaching of the recovered Scriptures, its own reformation was commenced and was followed by a conflict more extended and severe than any which had been waged against it before. And after more than three centuries and a half this conflict has not ceased. 16. Its next conflict, partly occasioned by the errors of Romanism and greatly aggravated by them, has been with infidelity in various forms. The Italian infidels of the 16th c. were witnesses against themselves by their hypocrisy and vice; the English infidels of the 17th and 18th centuries were driven back by many earnest writers; the French infidels of the 18th c. hastening on the revolution and greatly increasing its horrors, condemned their own religious errors by their political crimes; the German infidels of the 19th c., striving to dissolve Christianity into fable by the power of criticism, have left its foundations as solid as before. 17. The great conflict of Christianity in the present century is with the gigantic forces of modern heathenism. Having commenced the work

in the closing years of the last century, it has ever since steadily advanced with wiser counsel, more deliberate purpose, more thorough work, more liberal expenditure, and more enlarged success, to the overthrow of all false religions. A system of religion which has been contending so long against all these mighty forces; whose progress can be traced through 3,800 years, from the point where one man held its revelation as a promise of blessing for all the world, to the present time, in which millions enjoying the blessing themselves are pressing on the fulfillment among all nations—that system of religion must have more than human strength, it must be from God. The evidences by which its divine origin is established are co-extensive with human observation, thought, and history. A portion of them may be classified as follows:

I. EXTERNAL PROOFS. 1. Miracles wrought by Moses, Christ, and the apostles. 2. Prophecies already fulfilled and yet to be fulfilled; concerning Nineveh, Babylon, Tyre, Egypt, Petra, Bashan, Moab, Philistia, Damascus; the Babylonian, Persian, Grecian, and Roman empires: concerning the Jews, their deliverance from Egypt, entrance into Canaan, captivity in Babylon, restoration to their own land, destruction of their temple and capital city, with the long period during which it would continue trodden down by the nations, their wanderings and sufferings in many lands: concerning the Christian apostasy, the seven churches of Asia, and the unfolding of human history to the last days. 3. Historical testimonies to the genuineness and authenticity of the Scriptures.

II. INTERNAL PROOFS. 1. *Doctrines*. Concerning the being, perfections, and government of God; the origin of the worlds; the creation, nature, fall, sinfulness, redemption, and immortality of man. 2. *Moral and religious precepts*. The ten commandments; sermon on the mount; ethics of the epistles. 3. The person, character, and work of Jesus Christ; and the unity of all the Scriptures in him as the divine human Savior. In the Old Testament a deliverer is promised who would be one of the human race, yet would perform a work beyond human power; would descend from Adam, Abraham, Isaac, Jacob, Judah, David; would be born in Bethlehem, of a virgin mother, yet is eternal, the mighty God and Prince of Peace; would be subjected to humiliation, sorrow, suffering, death; and, because of these things, would be raised from the dead and exalted to the right hand of God as the Savior of men. The New Testament exhibits Jesus Christ as descended, in human nature, from Adam, Abraham, Isaac, Jacob, Judah, David, and born in Bethlehem of the virgin Mary; yet as in his divine nature the Son of God, Emmanuel, God with us: as subjected to humiliation, suffering, and the cursed death of the cross; yet rising again the third day and filling the New Testament, the church and heaven with his glory as God manifest in the flesh. This exhibition of Christ in all the Scriptures is a demonstration that he is the divine Savior and that they are inspired of God.

III. Experimental proof (combining both the external and internal) furnished by the rise and continued progress of Christianity and its effects on the character, condition, and hopes of mankind. Christianity contains a revelation from the living God, was founded by a living Savior, was embraced, through the power of the Holy Spirit, by living men, so that Christians existed before organized Christian churches, before the Christian Scriptures, before Christian customs, laws, or nations. Successive generations of Christians have been continued on the earth and have furnished living evidences of Christianity. The aggregate of Christian life, character, work, and influence throughout the world from the beginning to the present time is, to-day, the culmination of the proofs that Christianity is divine. See CHRISTIANITY.

EVIL may be generally defined as that which is opposed to the divine order of the universe. It requires only a superficial observation to perceive, that there are many apparent exceptions to the pervading harmony and happiness of creation: there are convulsions in the physical world; there are suffering, decay, and death throughout the whole range of organic existence; and the appellation of E. is commonly applied to such phenomena. In the face of the human consciousness, such phenomena appear to be infractions of the general order and good, and it pronounces them *evil*. How far the internal feeling of wrong has been quickened and educated by such outward facts, it would be difficult to say, but, beyond doubt, they have exercised upon it a powerful influence. Every form of religion testifies to the recognition of evil in the external world, and superstition in all its shapes mainly rests upon it.

But it is in the sphere of moral life alone that the conception of E. can be said to hold good. After the light of science has explored the secrets of nature, and shown how all its apparent anomalies are merely manifestations of a comprehensive harmony, the idea of E. is dispelled from the material and merely organic creation. "Whatever is, is best," is seen to be everywhere the law of this creation. There remains, however, the ineradicable feeling of E. in human life and manners and history. There is in the moral consciousness of man a sense of violated order, of transgression of divine law, or what is called *sin*, which is *evil* in its essential form. This fact of E. is everywhere appealed to by the Christian religion; it is the aim of this religion to deliver men from its power and misery. Every ethical and judicial code is based upon its recognition, and is designed to protect human society from its injurious consequences. It cannot be better or more clearly defined than in the language already given, *viz.*, the transgression of the divine law revealed in conscience and in Scripture.

The question of the *origin of evil* has been greatly discussed, and received various answers. The simplest and most direct of these answers is that which maintains a double origin of things, or a system of *dualism*. This conception lies at the bases of many forms of religion; it may be said to be the fundamental conception of all mere nature-religions. Interpreting the obvious appearances of nature, they embody in divine personalities its contending manifestations of light and darkness, benignity and terror. The opposition of Ormuzd and Ahriman in the old Zoroastrian faith is one of the most conspicuous examples of this religious dualism. Manicheism, which spread so widely in the 4th and 5th centuries, and the Syrian gnosticism from which it sprung, are also historical illustrations of the same principle. See AVESTA, ZOROASTER.

The dualistic theory of the origin of E., however, could not obviously maintain itself with the advance of speculation and the spread of Christian truth. It was no less clearly a postulate of the cultivated reason than a dictate of divine revelation, that the world proceeded from One absolutely Divine Creator, holy and good, of whom, and through whom, and to whom are all things. It was necessary, therefore, to reconcile the appearance of E. with this fundamental admission.

The doctrine of the fall, especially in the later form of development which connects it with the existence of a devil or evil spirit, tempting man in the shape of a serpent, was supposed to explain the appearance of E. in human history. Being tempted of the devil, man sinned, and so fell from his obedience to the divine law. This is the doctrine of orthodox Christian theology, and the answer which it gives to the inquiry, how sin came into the world? And many minds never think of carrying the inquiry further. It is clear, however, that this explanation of the historical origin of E. leaves the question of its real and absolute origin unsettled. The devil being assumed as the cause of man's sin, the further question arises, whence the devil? Is he an absolute personality? in which case we are landed in the old theory of dualism; or is he, according to the traditional Christian conception, a fallen angel? in which case the question just returns, whence the spring of E. in him? There is no real explanation gained by this removal of the question; it is still the same difficulty—whence the origin of E. in the creation of an all-perfect being, almighty as well as all-wise and good?

Speculation may please itself with ingenious answers to this question, but in truth it admits of no satisfactory solution. Some, for example, have argued that E., like darkness or cold, is an indispensable element of alternation or contrast in human life. All individual reality is only the product of opposite forces working together. Character could only arise from the interaction of opposing ethical influences of good and evil. In nature, we have attraction and repulsion, rest and motion, positive and negative electricity; why should it be different in the sphere of morals? Here, too, there must be polarity. Good can only exist in contradistinction to E.; the one no less than the other is necessary to constitute the drama of human life and history. Others, again, have argued, that E. is the result of what is called metaphysical imperfection. God alone can be perfectly good. The creature, in its very nature, is limited, defective; and E. is nothing else than the evidence of this limitation in man. It is not something real or positive, but only a privation. It is in morals what cold and darkness are in physics, a pure negation. Thus have argued such profound thinkers as Augustine and Leibnitz. But it requires but little penetration to see that such arguments, however ingenious, and so far well founded, do not meet the essential difficulty of the problem. If E. be, according to such views, a necessary element of human life, in the one case, in order to develop its activity, in the other case, as clinging to its creaturely limitations, then plainly it is not, in the orthodox sense of the word, *evil*. It is not, and cannot be a contradiction of the true idea of human life, and at the same time a necessary element of it. Whatever necessarily belongs to life, must help its true development, and not injure and destroy it; must be *good*, in short, and not *evil*. Such theories, therefore, only solve the problem by eliminating the fact. The origin of E. must remain forever inscrutable; nor is it wonderful that it should. It is only in its ultimate sense conceivable as a quality of moral freedom, and moral freedom in man or any created being is a profound mystery. It is something which "we apprehend, but which we can neither comprehend nor communicate." See PESSIMISM.

EVIL, KING'S. See SCROFULA.

EVIL EYE. Both in ancient and modern times, the belief that some persons have the power of injuring others by looking upon them, has been widely diffused. The Greeks frequently speak of the *ophthalmos baskanos* (or E. E.), which they conceived to be especially dangerous to children; and the Romans used the verb *fascinare* to express the same fact. Pliny speaks—not on his own authority, however—of "those among the Triballians and Illyrians, who with their very eyesight can witch (*effascinate*), yea, and kill those whom they look wistly upon any long time;" and Plutarch states, on the authority of Philaretus, that "the Thybiens who inhabited Pontus were deadly, not only to babes, but to men grown, and that whomsoever their eye, speech, or breath would reach, were sure to fall sick, and pine away." Menalcas, in Virgil (*Ecl.* iii. 102), also complains that some E. E. has fascinated his young lambs—

Nescio quis teneros oculus mihi fascinat agnos.

The principal amulet used by the ancients was the *phallus* or *fascinum*, as the Romans

called it, which was hung round the neck of children. Of course, this superstition, like all others, flourished in Europe during the Middle Ages. See Reginald Scot's *Discovery of Witchcraft*; the *Opusculum de Fascino* of John Lazarus Gutierrez, a Spanish physician, published in 1653; and the *Tractatus de Fascinatione* of John Christian Frommann, a physician of Saxe-Coburg, published in 1675. In the British isles, also, the belief in the power of the E. E. is of old date, and is by no means dead, at least in Ireland and the Highlands of Scotland. In these countries (as elsewhere), it was once a very common superstition that cattle were subject to injury in this way. Witches had the power to a malignant degree; and various charms, such as twining mountain-ash among the hair of the cow's tail, were used to avert or destroy their noxious influence. In the east it was and is no less prevalent. The Persians have various methods of discovering the special kind of fascination by which a person is afflicted; and Dallaway, in his *Account of Constantinople* (Lond. 1797) affirms that "nothing can exceed the superstition of the Turks respecting the E. E. of an enemy or infidel. Passages from the Koran are painted on the outside of the houses, globes of glass are suspended from the ceiling, and a part of the superfluous caparison of their horses is designed to attract attention, and divert a sinister influence." Hobhouse, in his *Travels*, bears equally conclusive testimony to the prevalence of this superstition in the Turkish empire, not among Mohammedans only, but also among Christians; while Lane, in his *Modern Egyptians* (1836), gives an account of the precautions taken by the Egyptians to avoid the influence of evil eye. The American Indians partake of the same belief; and it is not improbable that if the matter were still more profoundly investigated, it would be found that every nation that exists or has existed, with anything like a developed system of superstition, believes or has believed in the reality of fascination in some form or other.

The universality of this superstition goes far to prove that it has what may be called a *natural* origin; and, indeed, when we consider that the *eye* is the most expressive organ of the soul or mind of man, that through it are shot forth, as it were, into the visible world of the senses, the hidden passions, emotions, and desires of our nature, we will not wonder that in the "times of ignorance," when men could give no rational or scientific account of almost any physiological phenomena, if connected with psychology, the eye should have been superstitiously imagined to be a center of malignant influence. The eye is, in point of fact, as potent as superstition dreams: the error lay not in the recognition of its power, but in explaining the mode of its operation. The person who felt himself under the spell of a powerful gaze, was too agitated to calmly consider the cause of his terrors, and attributed to another results for which he himself was mainly responsible. It was really he that gave to the eye of his fellow-creature its baleful influence; and he quailed less before the force of character which it indicated, than before the fearful fancies with which his own timidity had invested it. For this disease, wherever it has existed, or does yet exist, there is no cure but that solid culture of the understanding from which comes a true strength of will and brain. See FASCINATION BY SERPENTS.

EVOLUTE AND INVOLUTE. See CURVATURE and OSCULATING CIRCLE. The evolute of any curve is the locus of the center of its osculating circle, and, relative to its evolute, the curve is called the involute. This is the simplest definition that can be given of an evolute and involute, which are relative terms. There is another, however, which may represent the relation of the curves more clearly to those who are not

mathematicians. If on any curve a string be closely wrapped, and if the string be fastened at one of its ends, and free at the other; and then if we unwind the string from the curve, keeping it constantly stretched, the curve which would be traced out by a pencil fixed to the free end of the string, is called the involute of that from which the string is unwound, and relative to it, the latter is called the evolute. It is clear that the involute might otherwise be described by fastening a string at one extremity of the evolute, and wrapping it thereupon, keeping it always stretched. From either definition, it is clear that a normal to the invo-

lute at any point is a tangent to the evolute, and that the difference in length between any two radii of curvature to the involute is equal to the length of the arc of the evolute intercepted between them. The nature of evolutes was first considered by Huyghens, who showed that the evolute to a common cycloid is another equal cycloid, a property of that curve which he employed in making a pendulum vibrate in a cycloid. To describe the involute of a circle, proceed as follows: Let *a* be the center of the circle, and *b* the extremity of the string to be unwound from its circumference. Divide the circle, or part of the circle, according to the length of curve required, into any number of equal parts, as *c, d, e*, etc.; through these, from *a* draw radial lines; from

the points where these touch the circle, draw, at right angles to the lines *ac*, *ad*, etc., other lines, as in the diagram. With the distance *cb* as radius, from the point *c*, describe an arc *b1*, cutting the line *c1* in 1. From the point *d*, with *d1*, describe an arc 1 2, cutting the line *d2* in 2. From *e*, with *e2*, describe an arc 2 3, cutting the line *e3* in 3. With radius *f3*, from *f*, describe an arc 3 4, cutting *f4* in the point 4. Proceed in this way, describing arcs which pass through the points 5, 6, 7, 8, and 9. The involute will thus be formed.

EVOLUTION. See SPECIES.

EVOLUTION AND INVOLUTION, algebraical terms, the former signifying the *extraction of roots*, and the latter the *raising to powers*. When any number is multiplied by itself, the product is called its square, or second power. If we multiply the square by the number again, we get the cube, or third power; and so on. This process is called involution. Evolution is the inverse process, by which a number being presented, we may ascertain a particular *root* of it, say the fourth; or that number which, being multiplied into unity a particular number of times, say four times, the product will be the number presented. Both subjects will be found treated in all algebraical text-books. Evolution is more particularly considered under the head **EXTRACTION OF ROOTS**.

EVOLUTIONS, in military matters, are the movements of troops in order to change position. The object may be to maintain or sustain a post, to occupy a new post, to improve an attack, or to improve a defense. All such movements as marching, counter-marching, route-marching, changing front, forming line, facing, wheeling, making column or line, making echelon or square, defiling, deploying, etc., come under the general heading of evolutions. More minute descriptions of these and other motions will be given under **TACTICS, MILITARY AND NAVAL**. Other things being equal, the best E. are those which occupy least time and least space. The word evolution equally applies to the movement of ships in a fleet.

EVORA (ancient *Ebora*), a city of Portugal, capital of the province of Alemtejo, and, after Coimbra, and perhaps Thomar, the most interesting city in the country, is beautifully situated on a fertile and elevated plain, 48 m. w.s.w. of Badajoz, and about 80 m. e. of Lisbon. It was once a place of considerable strength; but its ramparts, and the towers which flanked them, its citadel, its forts, and its watch-towers, are now in a hopelessly ruinous condition. The town itself is not well built, its streets are narrow and winding, and its houses old and badly planned. It has a cathedral, a large Gothic edifice, founded in 1186, the choir of which, rebuilt in 1721, is in the Italian style, and is richly adorned with marbles of various colors. E. has been the see of an archbishop since 1541; has an archiepiscopal library, containing upwards of 50,000 volumes; and several pictures of great merit, attributed to Gran Vasco. It has manufactures of ironware and leather, and a well-attended annual fair. Pop. '90, 15,134.

E. is a very ancient city. Quintus Sertorius took it in 80 B.C. It was also conquered by the Moors in 712, but recovered from them in 1166. The Roman antiquities of E. are unrivaled in the peninsula. Among these, the temple of Diana, used as a slaughter-house for some time previous to the year 1834, exhibits in its fine Corinthian columns admirable proportion and delicacy of sculpture. There is also an aqueduct, 1200 paces in length, erected by Quintus Sertorius; but the most beautiful Roman relic, and one of the most perfect pieces of ancient architecture in existence, is the tower which rises in the city at the extremity of the aqueduct. It is 12 ft. 6 in. in diameter, and is surrounded by eight columns of the Ionic order. Ionic pilasters decorate the second story, and the top is crowned with a hemispherical dome. It is wholly constructed of brick, and covered with cement of such a durable nature that, although this delicate structure has existed since 70 B.C., few parts of it seem to have been impaired by time.

EVREMOND, CHARLES MARGOTELLE DE ST. DENIS, SEIGNEUR DE ST. an author and wit of the 17th c., was b. at St. Denis-le-Guast, in Normandy, April 1, 1613. He entered the army about the age of 15, became an ensign in less than a year, and in 1637 had the command of a company of foot. About this time, he gained the favor and friendship of Turenne, Grammont, the prince of Condé, and others of high rank, all of whom were delighted with the wit and cheerfulness of his conversation. Having talked himself into the esteem of these men, it was not long, however, until, by the same means, he brought himself under their displeasure. In 1661 his unbridled indulgence in raillery compelled him to take refuge in England. Many attempts were made at the French court to induce Louis XIV. to recall St. E., whose accomplishments, gayety, and wit, rendered him the delight of all who had not smarted from his sarcasm; but Louis remained immovable until 1689, when he granted the exile permission to return. It was now, however, too late. St. E. had by this time surrounded himself with an admiring circle of the wits and beauties of the English court, and resolved to remain where he was. He died in his 91st year, in Sept., 1703.

St. E.'s works, comprising comedies, classical essays, etc., were first correctly published by Des Maizeaux, with a life of the author (Lond. 1705). The works are also translated into English by the same editor.

EVREUX (anciently *Mediolanum*, and more recently *Ebuorovices*), an episcopal city of France, in the department of Eure, of which it is the capital, is pleasantly situated in

a valley on the Iton, a feeder of the Eure, 60 m. w.n.w. of Paris. It is well built, its streets regular, and the environs prettily laid out in promenades, gardens, and vineyards. The principal building of E. is the cathedral, which dates from the 11th century, and is a composite of various styles of architecture; one of the most interesting features being the north portal built in the 16th century in the flamboyant style. The other buildings of note are the abbey church of St. Thaurin, originally built over the tomb of St. Thaurin, the first bishop of E. and having a shrine executed in the 13th c., which once contained his relics; the bishop's palace, built in 1484; and the *Tour de l'Horloge* of the same century. E. has a variety of manufactures, including cotton and woolen stuffs. Pop. of commune, 16,932.

E. is remarkable for the numerous sieges which it has sustained. It was taken by Clovis from the Romans; was sacked and plundered in 892 by the Northmen, under Rollo; was burned by Henry I. of England in 1119; and in 1194 and 1199 it was twice captured by Philippe Auguste king of France, into whose hands, after a short time, it permanently came. It was frequently taken and recovered in the wars between France and England during the reigns of Henry V. and Henry VI. of the latter country.

VIEL ÈVREUX (*Old Evreux*), a village near E., and the supposed site of the ancient Mediolanum, has some ancient remains of a theater, an aqueduct, and fortifications.

EWALD, GEORG HEINRICH AUGUST VON, one of the greatest orientalists of the 19th c., was b. 16th Nov., 1803, at Göttingen, and exhibited a predilection for oriental literature even in his school-days. He studied at the university of his native place, and while still a student, wrote a work on the composition of Genesis (*Die Composition der Genesis*, Braunsch. 1823). In 1823, he became a teacher at the Wolfenbüttel gymnasium; in 1827, extraordinary, and in 1831, ordinary professor of philosophy at Göttingen; and in 1835, was appointed nominal professor of the oriental languages. Travels in search of oriental MSS. led him, in 1826, 1829, and 1836, to Berlin, Paris, and Italy. After the death of Eichhorn, the critical exegesis of the Old Testament was included in his duties as professor of the oriental tongues. The first, and perhaps the most important fruit of his new labors, was his Critical Grammar of the Hebrew Language (*Kritische Grammatik der Hebr. Sprache*, Leip. 1827), an abridgment of which was published at Leipsic in 1835, under the title of Grammar of the Hebrew Language (*Grammatik der Hebr. Sprache*; 5th edit., 1844); and a still simpler epitome in 1842, entitled Hebrew Grammar for Beginners (*Hebr. Sprachlehre für Anfänger*). Before this, however, E. had acquired a high reputation by his work on Canticles (*Hohe Lied Salomo's*, Gött., 1826); his Commentary on the Apocalypse (*Commentarius in Apocalypsin*, Leip. 1828); his Poetical Books of the Old Testament, in 4 vols. (*Die Poetischen Bücher des Alten Bundes*, Gött. 1835-37); and his Prophets of the Old Testament, in 2 vols. (*Die Propheten des Alten Bundes*, 2 Bde., Stutt., 1840). Between the years 1843-50, E. published an important work, in 4 vols., on the History of the People of Israel until the Time of Christ (*Geschichte des Volkes Israel bis auf Christus*; Eng. trans. 1869-74), and a subsidiary volume on the Antiquities of the People of Israel (*Die Alterthümer des Volkes Israel*). The *Geschichte des Volkes Israel*, together with its two continuations, The History of Christ and his Time (*Geschichte Christus und seiner Zeit*, 1857), and the History of the Apostolic Age, etc. (*Geschichte des Apostolischen Zeitalters bis zur Zerstörung Jerusalems*, 1858), is regarded as E.'s greatest work. But Jewish history and literature did not limit the sphere of E.'s wonderful activity. His lectures at Göttingen embraced the literature of the Arabic, Persian, Aramaic, and Sanscrit tongues, and gave birth to such works as that on the Meters of the Arabian Songs (*De Metris Carminum Arabicorum*, Leip. 1825); on Some of the Older Sanscrit Meters (*Ueber einige ältere Sanscrit Metra*, Gött. 1827), an epitome of the Arabic author Wakidi's work on Mesopotamia (*De Mesopotamiae expugnata Historia*, Gött. 1827), and a Grammar of Arabic, entitled *Grammatica Critica Linguae Arabicae cum brevi Metrorum Doctrina*, 2 Bde. (Leip. 1831-33). In 1832, E. published at Göttingen several very important Dissertations on Oriental and Biblical Literature (*Abhandlungen zur orient. und biblischen Literatur*), and planned the well-known periodical, Journal for the Knowledge of the East (*Zeitschrift für die Kunde des Morgenlands*). E., however, was not only a scholar and philologist, but a man of strong political convictions. Having, along with six of his colleagues (the others were the brothers Grimm, Dahlmann, Gervinus, Weber, and Albrecht), protested against the abolition of constitutional law and liberty in Hanover by the new sovereign, Ernest Augustus (previously duke of Cumberland), he was dismissed from his situation, 12th Dec., 1837, and went to England to investigate its public libraries, whence he was called to Tübingen, in 1838, as professor of theology. Here he remained for ten years, during which he was involved in many strifes. In 1841, he was ennobled by the king of Württemberg. In 1848, E. returned to Göttingen, where he established a Year-book of Biblical Science (*Jahrbuch der biblischen Wissenschaft*), in which, as well as as in his work on the Synoptic Gospels (*Die drei ersten Evangelien*, Gött. 1850), and works on the Epistles of Paul (*Die Sendschreiben des Apostels Paulus übersetzt und erklärt*, Gött. 1857), he strove to give a firmer basis to New Testament criticism and exegesis. E. also paid great attention to Ethiopic literature, a result of which is his valuable Dissertation on the Book of Enoch (*Ueber des Äthiopischen Buches Henoch Entstehung, etc.*, Gött. 1856). Later works were *Das Sendschreiben an die Hebräer und Jacobus' Rundschreiben* (1871); and *Sieben Sendschreiben des Neuen Bundes* (1871). The distinguishing peculiarity of E., as a

theologian and critic, was his love for the concrete forms in which divine truths are revealed in history, and his dislike of the abstractions into which they are refined away by overspeculative theologians. He regarded it as the especial glory of the Jewish people, that they never lost sight of the concrete—as the Persians and Hindus, for example, did, with whom the realities of religion vanished into the most intangible dreams—but kept it ever before them until, in the fullness of times, there was born in their midst Jesus of Nazareth, the Perfect and Only One, in whom humanity reached its spiritual consummation. E. refused to class himself or to be classed with any theological party in Germany. He was equally opposed to the extreme left represented in Tübingen, and to the extreme right represented in the modern Lutheran movement headed by Hengstenberg. When Hanover was, in 1866, incorporated with Prussia, E. declined to take the new oath of allegiance, and was accordingly required to retire from the functions of the professoriate. He returned to political life; and as the three times elected representative of the town of Hanover in the Reichstag, persistently opposed the new political conditions. He d. May 4, 1875.

EWALD, JOHANNES, one of the best lyric poets of Denmark, was b. at Copenhagen on the 18th Nov., 1748, and d. in the same city in 1781. In his 16th year, when his friends were about to send him to the university of Copenhagen, he made his escape to Germany, where he entered as a private soldier in the army of Frederick the Great of Prussia, from which he soon deserted to the Austrians. He induced his friends to purchase his discharge, and returned to Copenhagen in 1760, after having taken part in the great campaigns of 1759–60. The first production of E. which attracted general notice was the funeral ode which he wrote on the death of Frederick V. of Denmark in 1767, and which exhibited so much original genius that it at once raised the young poet to the rank of one of the best writers of his country. In 1770, appeared the prose tragedy of *Rolf Krage*, which gives evidence of a careful study of Shakespeare and the English dramatists of the Elizabethan age. Although *Balder's Deed* (1773), which breathes the heroic spirit of the ancient bards of the north, and exhibits the specially national tendency of E.'s genius, is regarded by some critics as his *chef-d'œuvre*, *Fiskerne*, "The Fisherman" (1780), probably deserves to rank equally high, when considered as a mere lyrical production. His habits of dissipation, and the decided opinions which he expressed in reference to politics, brought him into difficulties of every kind, while his infirmities of temper, and irregularities of conduct, estranged the affection of his nearest relatives, and in the latter years of his unhappy life he was often indebted to the charity of strangers for the means of subsistence. Some of his nautical songs have been raised to the dignity of national odes, and many of his occasional pieces rank among the sweetest poems of his country. He was engaged at the time of his death in compiling an autobiography, and in bringing out the complete edition of his writings, which finally appeared in 1792. His works have also been edited by F. L. Liebenberg (Copen. 1850–55); and a life of E., compiled from hitherto unpublished materials, has recently appeared from the pen of F. C. Olsen, of Copenhagen.

EWBANK, THOMAS, 1792–1870; b. England. He emigrated to New York in his youth, and was appointed commissioner of patents in 1849. He published, besides other works, a *Descriptive and Historical Account of Hydraulic and other Machines, Ancient and Modern*; and *Thoughts on Matter and Force*.

EWELL, BENJAMIN STODDERT, 1810–94; b. District of Columbia; educator; graduated at the U. S. military academy, 1832; assistant professor there, 1832–36; resigned commission, 1836; professor of mathematics and natural philosophy, Hampden-Sydney college, 1839–46, at Washington college, 1846–48, at college of William and Mary, 1848–9; professor of mathematics and natural science at the last college, 1849–61, and president there, 1854–88; and became colonel and adjutant-general in the confederate army.

EWELL, RICHARD STODDERT, 1817–72; b. District of Columbia; graduated at West Point, served on the western frontier, on the coast survey, and in the war with Mexico—being engaged at Vera Cruz, Cerro Gordo, Contreras, Churubusco, Molino del Rey, and Chapultepec; was captain of dragoons in 1849, and was engaged on the Gila and Pinal Apache expeditions. He joined the southern forces in the war of the secession, serving in the Manassas campaign, at Blackburn's Ford and Bull Run, at White Oak Swamp and Cedar Mountain; was defeated at Kettle Run, was in the second battle of Bull Run, and was wounded in the Maryland campaign; became lieut. gen. in 1863, succeeding Stonewall Jackson. He was taken prisoner April 6, 1865, a few days before the close of the war.

EWER, FERDINAND CARTWRIGHT, D.D., 1826–83; b. Nantucket, Mass. graduated at Harvard Coll., 1848; went to California, 1849, and became an editor; but in 1858 entered the Prot. Epis. ministry. He held rectorships in San Francisco and in New York, founding St. Ignatius church in the latter city, 1872. He published *Catholicity in its Relation to Protestantism and Romanism*, 1878; *Grammar of Theology*, 1880, etc. He was a very earnest writer and worker, taking—as in his *Protestantism a Failure*—extreme ground in favor of what has been termed the Romanist re-action in the Prot. Epis. church.

EWING, a co. in n. western S. Dakota, on the Montana border, formed 1883 from part of Harding; 1008 sq. m.; pop. '90, 16.

EWING, FINIS, 1773-1841 ; b. Va. ; one of the fathers of the Cumberland Presbyterian church. He was licensed to preach, and in 1803 was ordained by the Cumberland presbytery. His ordination not being recognized by the Kentucky synod, the presbytery being dissolved, and the action of the synod being sustained by the general assembly, he with two others, in 1810, formed the nucleus of the denomination known as the Cumberland Presbyterian church. In 1820, he removed to Missouri, where he died.

EWING, JULIANA HORATIA ORR (GATTY), 1842-85 ; an English writer ; was the daughter of the Rev. Alfred Scott Gatty and his wife, Margaret Gatty, and was born at Ecclesfield, Yorkshire. Her mother was the author of *Parables from Nature* and other books, and in 1806 started *Aunt Judy's Magazine*, to which her gifted daughter contributed. After the death of Mrs. Gatty, in 1873, Juliana and her sister conducted the magazine for a time. In 1867, Miss Gatty married Major Alexander Ewing, who was himself an author. Miss Gatty's books described child-life, and were professedly written for children, but gained a larger circle of adult readers by their charming and simple style. They include *Mrs. Overthway's Remembrances* ; *Jackanapes* ; *Jan of the Wind-mill* ; *Lob-lie-by-the-Fire* ; *Six to Sixteen* ; *A Flat Iron for a Parthing* ; *We and the World* ; *A Great Emergency* ; *Old-Fashioned Fairy Tales*, and the pathetic *The Story of a Short Life*.

EWING, THOMAS, LL.D., 1789-1871 ; b. Va. ; educated by his own exertions, and admitted to the bar in Lancaster, O., in 1816, soon becoming a prominent and successful lawyer in that state. In 1831, he was sent to the U. S. senate, where he soon became known as opposing the confirmation of Martin Van Buren as minister of England, and President Jackson's measures generally. In 1841 he was appointed by President Harrison secretary of the treasury. Disagreeing with President Tyler (who succeeded Harrison only a month after the latter's inauguration), Ewing, with all the other cabinet officers, except Webster, resigned. Under President Taylor he was the first secretary of the new department of the interior, and when Fillmore succeeded Taylor he was appointed senator from Ohio for the unexpired term of Mr. Corwin, then appointed secretary of the treasury. He retired from public life in 1851.

EWING, THOMAS, JR., b. Ohio, 1829 ; son of Thomas. He was chief-justice of Kansas, and served in the union army during the war of the secession, rising to brevet maj.gen. of volunteers. He was a member of congress, 1878-81, where he was a leading democratic advocate of what are known as "greenback views;" was unsuccessful candidate for governor of Ohio in 1879; and subsequently practiced law in New York. He d. in 1896.

EXAMINATIONS FOR THE PUBLIC SERVICE. See CIVIL SERVICE; CIVIL SERVICE REFORM.

EXANTHEMATA (from a Greek verb, to effloresce, or come out in a rash), a class of febrile diseases (see FEVER) attended by distinctive eruptions on the skin, appearing at a definite period, and running a recognizable course. To this class belong small-pox, chicken-pox, measles, scarlet fever, and, according to some authorities, plague, typhus, erysipelas, etc.

EXARCH was the title first conferred by Justinian on his commander-in-chief and vicegerent in Italy. The conquest of Italy by the Goths in the early part of the 6th c. was a severe blow to the Byzantine pride; and Justinian determined to wipe out the disgrace, and recover the imperial territories. The execution of this project was intrusted at first to Belisarius (q. v.), and afterwards to Narses (q. v.), by whom the reconquest of Italy was effected. The latter was the first who bore the title of E. ; and the district over which he ruled was called the *exarchate*. The seat of the exarchs was Ravenna, the different towns and territories belonging to them being governed by subordinate rulers, styled *duces* or dukes. The extent of the exarchate, however, was gradually diminished, until it embraced only the country about Ravenna, the present Romagna, and the coasts of Rimini as far as Ancona. This was brought about partly by the conquests of the Longobards, partly by the dukes of Venice and Naples making themselves independent. In the year 728, even this small portion fell, for a short time, into the hands of the Longobards. In 752, Astulf, or Astolphus, king of the Longobards, put an end to the Byzantine rule at Ravenna; but in 755, he was compelled to resign the exarchate to Pepin the less, king of the Franks, who gave it over to the bishop of Rome, Stephanus II.—In the Christian church, E. was originally a title of the bishops, afterwards of a bishop who presided over several others—a primate. It was borne by the bishops of Alexandria, Antioch, Ephesus, Cæsarea, and Constantinople, till it was finally exchanged for the title of patriarch. A superior over several monasteries was also called in ancient times an exarch. The same title is also borne, in the modern Greek church, by the person who "visits" officially, as a sort of legate of the patriarch, the clergy and churches in a province.

EXCALIBUR, the famous sword of King Arthur (q. v.), bestowed upon him in accordance with the promise of Merlin by the Lady of the Lake, and at his death thrown by one of his faithful knights back into the waters of the lake, where it was grasped and borne beneath the surface by a mystic hand.

EXCELLENCE, or **EXCELLENCY**, a title now given to ambassadors, as representing not the affairs alone, but the persons of sovereign princes, to whom it was formerly applied. The privilege of being addressed as "your excellency," and of demanding a private interview with the ruler to whom he is accredited, are the chief distinctions between the privileges of an ambassador and an envoy or minister plenipotentiary. In the U. S., the governors of New Hampshire and Massachusetts are legally entitled to be addressed as "Your Excellency": elsewhere the address is by courtesy only.

EX CATHEDRA (Latin, meaning literally, from the chair, *cathedra* being the chair or seat of a person in authority, as of a bishop or lecturer), a phrase originally used with reference to the decisions of the pope or others high in authority, who, literally speaking, pronounced their judgments *ex cathedra*. The expression is now applied to authoritative assertion in general, e.g. to speak *ex cathedra* is to speak as if vested with full authority, without fear of contradiction or opposition. See **CATHEDRAL**.

EXCHANGE, a term applied to buildings or places of resort for merchants. The name *bourse* (purse) is applied in France and Belgium to a resort of this kind; and in Berlin, Hamburg and other German cities there is the equivalent word *börse*. Exchanges have usually comprehended an open quadrangle surrounded by an arcade, free to all persons; but in some cases large reading rooms constitute resorts of this kind, and these are only open to a body of subscribers and visitors whom they introduce. Gathering places for merchants existed at an early date in Venice, Genoa and other Italian cities; but the modern exchange originated in the early part of the 16th century in the commercial cities of the Netherlands and Germany. From the Netherlands they were introduced into England by Sir Thomas Gresham, who, having resided as British agent at Antwerp in 1850, chose the bourse of that city as a model for the royal exchange of London, which was ceremoniously opened by Queen Elizabeth in 1570. Their institution in England is therefore coincident with the rise of commercial prosperity in the middle of the 16th century. The present royal exchange was founded in 1842, and completed in three years at a cost of £150,000. There are many other exchanges in London, but for especial purposes, such as the coin exchange, coal exchange, etc.; and in recent years there have been numerous additions to the list of exchanges in the large towns of England and Scotland. See **STOCK EXCHANGE**.

Of the exchanges in the United States, the most noteworthy, from an architectural point of view, is the Merchant's Exchange of New York, on Broad St., near Wall. It was founded in 1817, and the first building, on Wall between Pearl and William Sts., was completed in 1827. This being destroyed by fire in 1835, a new building was erected on the old site, but afterwards sold to the government to be used for a custom house. In most of the important cities of the United States there are exchange buildings, generally of large size. Other celebrated exchanges are the bourse of Paris, opened in 1824, and that of Hamburg. The latter is a general exchange in which the different branches of business are represented by separate departments and bureaux. It has among its attractive features, a library of over 50,000 volumes, and is one of the principal objects of interest in the city to the traveller. The exchanges of St. Petersburg and Amsterdam are also buildings of great size and beauty.

The term exchange seems to have been naturally adapted from the circumstance that the buying and exchanging of merchandise and also the exchanging and paying away of money formed the chief object of concourse. The vast number of transactions and the increasing complexity of our commercial system have intensified the tendency to form associations of this character for the purpose of procuring uniformity, promoting fair dealing, and settling disputes without recourse to litigation, until they have become most conspicuous and necessary factors in the modern business world. Thus there is a stockbroker's exchange, where the validity of investments is carefully investigated and the value of new securities subjected to the most searching examination before they are admitted to be bought and sold upon exchange, thereby insuring to a great extent the certainty and security of business transactions; a produce exchange, which investigates the staple food products, prevents adulteration, adopts marks or brands whereby the goods are known in all the markets of the world, establishes grades according to quality, and takes note of the different methods of preparation for exporting; and cotton exchanges, serving similar purposes in places where this staple is extensively purchased and sold. Exchanges have been established for almost every important class of commodities; but instances are not wanting, as in the case of the Hamburg exchange, already mentioned, where many different kinds of business are represented by departments devoted to their respective requirements. A numerous and important class of exchanges in the United States is the mechanic's exchange. This, as well as the real-estate exchange, is found in almost every considerable town.

EXCHANGE, in political economy, refers to the exchange of wealth. The classical school of economists divided the science into four departments, that is, production, exchange, distribution, and consumption. In accordance with this division, the department of exchange has to do with the phenomena of value in all its phases, the interaction of supply and demand, the laws of price and of credit, and all matters affecting the circulating medium. Later writers have discarded the division of political economy by these hard and fast lines, recognizing the difficulty of classifying all economic phenomena under one or another of these heads. Exchange arises from the division of labor. In the earlier stages of society, when the individual produced all that was necessary for his own support, there was no need of exchange. The next stage was that of

barter, by which a man secured what he wished by giving for it some commodity that he himself had produced. This clumsy system sufficed for the needs of the primitive man, but became utterly inadequate as trade expanded and society grew more complex. It depended upon what has been called the double coincidence of wants, namely that the would-be purchaser should be able to find a would-be seller having the article which the former desired and desiring the article which the former possessed, and that each possessed the articles in question in exchangeable quantities. Hence arose the need of a medium of exchange to serve as a measure or common standard of value. As the division of labor renders exchange necessary, so it is itself promoted by every advance in exchange. In other words, the exchange of commodities and the division of labor are mutually dependent. The importance of exchange is so great that some economists have favored changing the name of their science from political economy, or economics, to the science of exchange, for political economy concerns itself exclusively with the laws of wealth, and wealth is inconceivable apart from exchange. The ratio in which commodities exchange for each other determines value, and the value of an article, expressed in terms of some one commodity, is called price. The question whether anything that cannot be exchanged may still be wealth, has given rise to long controversy. One class of writers would include under the term wealth such abstractions as personal honesty, intelligence, and skill, since these qualities, when embodied in a workingman, enable him to command a higher price for his services. Others would rigidly exclude from the list of items to be classified under wealth, all things which are incapable of being detached from the person or the possessor. See the articles **VALUE, DEMAND AND SUPPLY, MONEY, and POLITICAL ECONOMY.**

EXCHANGE is applied in a special and technical sense to the conversion of the money of one country into its equivalent in the money of another. The technical meaning of the word has now, however, come to be the difference between the actual value of money taken by the standard of bullion, in any two places with relation to each other. If in New York it requires more than \$500 to pay a debt of that amount in London, the rate of exchange is against the former town and in favor of the latter, an inhabitant of which can pay a debt of \$500 in New York with less than that amount of bullion in London.

The operations of exchange are based on the principle of the cancellation of indebtedness, and can be best explained by simple example. If a New York merchant, A, buys goods worth 1000 ounces of gold for a London merchant, B, and seeks to discharge his indebtedness without having recourse to the cumbrous expedient of exporting specie, he endeavors to find some one who, having gold or a right to demand gold to that amount in London, is willing to transfer his claim for the amount thereof, or for so much more or less as the rate of exchange is for or against the latter city. A purchases the credit of this third party, C, and sends an order demanding its payment to his creditor, B, who thus in turn becomes the creditor of another London merchant. Now the amount that A will have to pay C for the value of the 1000 ounces of gold in London will depend upon the par of exchange. If exchange is at par between the two places, a certain amount of money metal in the one place will command an exactly equal amount of the same metal in the other, and in the above case A would have to pay C the equivalent of the 1000 ounces in gold; but if exchange is above or below par, in the one case a larger, and in the other a smaller amount of the money metal would be required in the place where the claim is purchased. If the debt, or any part of it, cannot be met by such an adjustment out of cross debts and credits, it will be necessary for the debtor to send bullion to his creditor; and this, being an expensive process, throws the rate of exchange against the debtor who so pays. For instance, if C's claim in London amounted to only 500 ounces of gold, then A would have had to be at the expense of sending the balance to London. No such actual transactions take place in the existing mercantile world, because the accounts in debtor and creditor connected with the town referred to are to be counted in thousands, and ramify into other towns; but the above example may be held to represent groups of debtors and creditors, as algebraic signs represent quantities. The individual merchants in one trading town have no idea how the surplus of debt or credit may be between them; far less can they tell how it may be adjusted by debts and credits in other towns; but through the agency of bankers, bill-discounters, and other persons who deal in money, the relations of all trading-places toward each other are in a constant state of shifting and adjustment; and any one who has to pay a debt in any trading-place can find out how much he has to give to get that debt paid, and can pay it accordingly. When, through the operation of these complicated transactions, you require to give more than \$500 in New York to get that amount paid in London, then the rate of exchange is against New York and in favor of London, where less than \$500 in cash will pay a debt of \$500 in New York. The difference will generally depend on the difficulty of adjusting questions of debt and credit throughout the commercial world, in such a manner as to get the debt paid. If it cannot be paid by adjustment, then bullion must be sent; and thus it is generally said, that the rate of exchange against any place is limited by the charge of exporting bullion. The rate of exchange is liable to be brought to a level also by commercial exportation and importation, since, whenever it is expensive to get money sent to a country, there is a temptation to send goods to that country to compensate the debt. In the general circle of transactions of this kind, the state or town which has the largest amount of transactions will have the largest number of debtors and of creditors, and will afford the chief facility for each compensating the other.

It is thus that London is the centre of the money market, where all the debits and credits of the world may be said to meet and extinguish each other. Exchange is at par between two places when the debts due from the one to the other within a given time exactly balance, and there is an equal demand in each for bills of exchange upon the other. If, however, the merchants of one place, say New York, are required within a given time to make a greater sum of payments to the merchants of another place, say London, than the latter have to make in New York, then exchange on London will be above par in New York. While the old notions about the balance of trade (q.v.) existed, it was supposed that the nation which the exchange was against was going to ruin; while that which it was in favor of was prospering through the other's loss. At present it is inconvenient and expensive to a country to have the exchange against it. An adverse exchange generally indicates a sort of break in the circle of trade which it would be advantageous to fill up, and *may* be caused by the commerce of a country decreasing; on the other hand, however, the imports for which a country pays in cash or in expensive bills, may be the same as a highly advantageous traffic. Gold-producing countries find bullion their most advantageous export, and the same is the case with countries into which gold has flowed in excess.

EXCHEQUER, CHANCELLOR OF THE. The office of chancellor of the exchequer, in Great Britain will be accurately described when we say that he is the first finance minister of the crown. Strictly speaking, he is the under-treasurer, the office of lord high treasurer being now vested in the lords commissioners of the treasury. When the prime minister is a member of the house of commons, he sometimes holds the office of chancellor of the exchequer. The judicial functions of the chancellor of the exchequer may now be considered matter of history. See **EXCHEQUER, COURT OF**. When the chief baron and the barons are equally divided in opinion, he may be required to rehear the cause with the barons, and to give his opinion. But the last instance in which this was done was in 1735; and though the decision which sir Robert Walpole gave is said to have given great satisfaction, the custom is not likely to be reverted to.

EXCHEQUER, COURT OF, which was abolished as a separate court by the Judicature Act of 1873, and its jurisdiction transferred to the new High Court of Justice, was the court wherein matters relating to the royal revenues were adjudicated upon. It is said (Madox, *Hist. of Ex.*) to have existed from the early times of the Conquest, and was denominated *scaccarium*, from *scaccus* or *scaccum*, a chessboard, from the fact that a chequered cloth was wont to be laid upon the table of the court; but under the Norman kings it was probably nothing more than a branch of the *Aula Regia*, or great council of the nation. From the reign of Henry III. its existence as a separate court was recognized. Its special business was, as before, the decision of revenue cases, but from an early period the lawyers showed a tendency to extend its jurisdiction over the ordinary litigious business—the common pleas—of the country. This was done by establishing the fiction that all lieges were the crown's debtors, whereby the court of exchequer acquired a concurrent jurisdiction with the other courts of common law. Besides its common law of jurisdiction, the Exchequer was distinguished from the King's Bench and Court of Common Pleas by having an equity side, but this was abolished in 1841, and its equitable jurisdiction transferred to the court of chancery. The judges of the exchequer consisted originally of the lord treasurer, the chancellor of the exchequer, and three puisne judges; these last were called barons of the exchequer. The chancellor of the exchequer sat only on the equity side of the court; he has not been called upon to exercise his judicial functions since 1735. The division of the high court, which still retains exclusive jurisdiction of the original court of exchequer, had, 1873–81, six judges—viz., the chief baron, and four barons of exchequer. From this division the appeal was to the court of appeal.

The court of *exchequer chamber* was formerly a court of all the judges in England assembled for decision of matters of law (Coke, *Inst. IV.*, 110, 119). Originally established in the reign of Edward III., for the purpose of reviewing the decisions of the common law side of the court of exchequer, it developed into a general court of error, in which capacity it revised the judgments of the other two courts of common law as well. In the reign of Elizabeth it was enacted that the judges of the common pleas and exchequer should form a second court of exchequer chamber, for review of certain cases in the queen's bench. But this intermediate court of appeal was abolished by the Judicature Act of 1873, as inconveniently composed, and somewhat unnecessary. An appeal now lies from each division of the high court of justice in England direct to the court of appeal, which succeeded to the jurisdiction formerly vested in the house of lords, as the supreme court of appeal, and consists of the lord chancellor, and the chiefs of the divisions, and the judges of the privy council.

In Scotland, before the union, the exchequer was the king's revenue court. A new court was established in the reign of queen Anne having a privative jurisdiction as to questions relating to revenues and customs of excise, and as to all honors and estates real and personal, and forfeitures and penalties arising to the crown within Scotland. But questions of *title* to honors, lands, etc., were reserved to the court of session. The judges of the court were the high treasurer of Great Britain, the chief baron and four other barons; and English barristers as well as Scotch advocates were allowed to practise in the court. By a statute of William IV, it was provided that successors should not

be appointed to such of the barons as should retire or die, and that the duties of the court should be discharged by a judge of the court of session. And now, by 19 and 20 Victoria, c. 56, the court of exchequer is abolished and the jurisdiction transferred entirely to the court of session.

The court of *exchequer chamber* in Ireland was established by 40 George III., c. 39, but was abolished as an intermediate court of appeal between the Irish courts and the high court in England.

EXCHEQUER BILLS, bills issued at the exchequer under the authority of acts of parliament, as security for money advanced to the government. They contain an engagement on the part of the government for the payment of the principal sums advanced with interest. These bills form the chief part of the unfunded debt of the country. They were first issued in the reign of William III., in the year 1696, and were drawn for various amounts from £100 to £5. At that time they bore interest at the rate of 3*d.* per day on £100 (Macaulay's *History of England*, iv. 700). The interest was reduced to 2*d.* during the reign of Anne. During the war 1793-1814, the rate of interest was usually 3½*d.* At present, it is generally from 1½*d.* to 2½*d.* per £100 per diem. Holders of these bills are exempt from all risk, except that arising from the amount of premium or discount they may have given for them. The bills pass from hand to hand as money, and are payable at the treasury at par. They may also be paid to government in discharge for taxes. When it is intended to pay off outstanding exchequer bills, public notice is given by advertisement. The advances of money to the government by the bank of England are made on exchequer bills. These bills are a convenient means whereby the government can meet a sudden demand for unusual expenditure. The amount of exchequer bills unprovided for in 1880-81 was £5,162,800. Another portion of the unfunded debt is constituted by exchequer bonds, with fixed rates of interest for definite periods.

EXCHEQUER TALLIES, seasoned wands of ash, hazel, or willow, formerly used for checking accounts in the English exchequer. The sum acknowledged was inscribed on the tally, on the other side of which the same sum was inscribed in Roman characters, together with the payer's name. Notches marked upon the tally indicated by their form the class to which the account belonged. This tally was split, and the payer received one half, which he presented for payment, and which was first matched with the half remaining in the office. It is said that this rude device, which was retained till 1783, was a very perfect protection against fraudulent claims.

EXCIPIENT (Lat. *excipio*, I receive), an inert or slightly active substance, introduced into a medical prescription as a *vehicle*, or medium of administration for the strictly medicinal ingredients. Thus conserve of red roses, or bread-crumbs, is used to make up pills; sulphate of potash, or white sugar, in medicinal powders; water, mucilage, white of egg, and many other substances in fluid mixtures.

EXCISE, the name of a tax on commodities, from the Latin *excisus*, cut off, as being a portion of the value of the commodity cut off and set apart for the revenue before the commodity is sold. This is not its actual nature, however, for the manufacturer, who looks for a profit on his outlay, does not give part of the value to the revenue; he merely counts the tax as part of his expenditure, which he intends to get back with a profit, so that it constitutes an addition to the ultimate price which the purchaser or consumer has to pay. A tax on commodities bought and sold is a very obvious one, but it has generally appeared in the simple shape of a toll on goods brought to market, and the complicated arrangements for officially watching the process of a manufacture for the purpose of seeing that none of the dues of the revenue are evaded is of comparatively modern origin. Though a tax corresponding to our excise appears to have been occasionally levied in very early times, it was first introduced under that name into England by the Long Parliament, who established an excise on liquors in 1643, with the promise of repeal at the end of the war, but when the land tax was removed or greatly diminished, and revenue from that source was no longer sufficient, it was found impossible to dispense with this new method of supply to the treasury. Though always unpopular, the excise in some form or other has ever since continued to be a material element in the taxation and revenue of Britain.

In the earlier part of the last century, sir Robert Walpole entertained the notion of enlarging its productiveness, while mitigating its proportional pressure by the bonding system, which suspends the exaction of the duty until the goods are sold, and thus leaves the manufacturer all his capital to be devoted to production. His plan involved the ultimate extension of the excise until it should virtually become the sole source of revenue, in the hope that by diminishing the number of taxes, greater simplicity and economy would be secured in their collection, while the substitution of an import on domestic commodities for the customs would destroy smuggling, introduce an error of free trade, and render England a vast free port for the world's commerce. But the rumor of an enlargement of the unpopular excise duty created a general excitement, and the memorable cry of "Liberty, Property, and no Excise," compelled Walpole to abandon the project. The great wars in the reigns of George II. and George III. having necessitated a further extension of the excise and an increase of its rate, it grew more productive from decade to decade, and from 1780 to 1825 its returns generally exceeded those of the customs. In the mean time, the diminution of the land tax still

continued. The reform of the excise began in 1822, and several articles were placed on the free list in that year and in the succeeding period, but this movement ceased in 1836, and no further reductions were made until the matter was again taken up under the leadership of sir Robert Peel, and a course of gradual reduction of the rates was entered upon, while many commodities previously taxed were relieved from the excise. Notwithstanding this reduction, the revenue from the excise rose rapidly, thus braving out the rule that a reasonable reduction of high taxes upon consumption increases the revenue. The only excisable articles in Great Britain at the present time are spirits, beer, tobacco, chicory, and the passenger receipts of railway companies.

Some account of the working of the tax in England has been necessary from the fact that the excise system in the United States is based upon the English system, the colonies having largely copied the legislation of the mother country in this particular, and having inherited the dislike of the excise in any form. Nevertheless, Pennsylvania, Massachusetts, and Connecticut were forced to an early imposition of a tax on spirits. But great reluctance was manifested to the granting of this power to the federal government, and we find several states in 1790 trying, through their representatives in the first congress, to procure the passage of an amendment to the constitution forbidding the general government ever to resort to this form of tax. Secretary Hamilton, however, insisted on the necessity of an excise on spirits, of which the consumption was excessive, and a tax was finally imposed, varying from nine to twenty-five cents per gallon on spirits distilled from articles produced in this country. The rates were somewhat reduced in 1792, but subsequently the tax was extended to other articles, refined sugar, snuff, and auction sales being included in the list, and stamp duties imposed on various instruments of exchange. The opposition finally culminated in the Whiskey Insurrection (q.v.) in Pennsylvania, and when Jefferson became president he proposed the abolition of the entire system, the revenue from the customs having rapidly increased. Congress fell in with his views, and the tax was removed, not to be restored until the necessities of the War of 1812 led to the passage of an act levying certain taxes which were afterward repealed in 1817, and no excise was imposed till the war of the secession. Our present system dates from July 1, 1862, a variety of taxes being needed to meet the exigencies of war times, but when the pressure was removed after the war the list of taxable articles was rapidly curtailed, until almost the entire revenue was raised from the excise on spirits and tobacco. These, in 1875, yielded 89 per cent. of the total produce of the internal revenue system, and they still continue to constitute far the most productive source of our revenue. It has seemed to be the policy of the United States to employ the excise system in its widest extent only in time of war, and as soon as the financial strain is removed, to recur to an excise upon luxuries alone. This may be ascribed partly to the inherent dislike of the tax itself and partly to the desire of the protectionists for a revenue derived solely from duties on imported goods. All other nations obtain part, and some a large part, of their revenue from an excise. At the present time, in the United States, the articles upon which the excise is levied are alcoholic liquors, tobacco, oleomargarine, and the circulation of Banks. In 1895 the excise on spirits yielded \$79,862,627; tobacco, \$29,707,908; fermented liquors, \$31,640,618; oleomargarine, \$1,960,794; banks, 1,704,007. In 1896 the total ordinary revenue was \$409,475,409. Previous to 1864 the receipts from the internal revenue system were uniformly less than the customs, but in that year the former amounted to \$109,741,134, while the customs yielded \$102,316,153, and the internal taxes continued to supply the larger portion of the revenue till 1874, when their receipts fell to \$102,409,785, the customs amounting to \$163,103,834 in the same year. Since that time the customs have always been in excess. In 1890 the customs produced \$229,668,585; the internal revenue taxes but \$142,606,706; but from 1890 to 1896 the difference in their productiveness was not so great, revenue from customs in 1896 being \$160,021,752, and from the excise \$146,762,865.

An excise, when compared with other taxes, has its good and its bad features; it is a method of extracting money for national purposes as expenditures on luxuries, and is especially serviceable when fed from those luxuries the use of which in excess becomes a vice. On the other hand, it renders necessary a system of inquisitorial inspection not only very offensive to all free people, but very open to abuse and fraud, while the manufacturer is at times obliged to employ a more expensive and inconvenient process and to forego the introduction of improvements in order to conform to governmental regulations, the cost of such unnecessary labor falling eventually upon the consumer. Moreover, checking the demand by artificially raising the price of a commodity in this way may often retard the growth of a rising industry. Though counteracted in a measure by the bonding system, the necessity of a larger capital for the manufacture of excisable articles fosters a sort of monopoly by its tendency to check competition; and since the manufacturer must realize profits on that part of his capital which is applied to the payment of taxes, as well as what is directly employed in the production of the article, the price to the consumer is greatly increased. These objections do not, however, invalidate the advantages of the excise system in this country, where the luxuries, spirits and tobacco, bear the chief burden of the tax; and it is the common opinion that a low excise on articles of luxury is the most productive as well as the least objectionable of taxes. See FINANCE; STAMP ACT; STAMPS; TAX.

EXCITANTS, or **STIMULANTS**, are those pharmaceutical preparations which, acting through the nervous system, tend to increase the action of the heart and other organs. They all possess more or less of a pungent and acrid taste, and give rise to a sensation of warmth when placed on a tender part of the skin. The class is a very numerous one, and the application of excitants or stimulants to the human subject should always be under the supervision of a qualified medical practitioner.

EXCITO-MOTOR ACTION. See **NERVOUS SYSTEM**.

EXCLUSION BILL, a proposed measure for excluding the duke of York, afterwards James II., from the succession to the throne, on account of his avowed Catholicism. A bill to this effect passed the commons in 1679, but was thrown out by the upper house. As the new parliament summoned in 1681 seemed determined to revert to this measure, it was dissolved, and Charles ruled henceforth without control. See **CHARLES II.**, **JAMES II.**

EXCOMMUNICATION is exclusion from the fellowship of the Christian church. The ancient Romans had something analogous in the exclusion of persons from the temples and from participation of the sacrifices, which persons were also given over with awful ceremonies to the furies. The Mosaic law decreed E. in case of certain offenses; and the intimate connection of things civil and ecclesiastical under the Jewish polity, rendered it terrible even as a temporal punishment. The Jews, in practice, had three degrees of excommunication. The first, *niddui*, was an exclusion from the synagogue for thirty days, that the offender might be ashamed. The second, *cherem*, was also for thirty days, but, besides exclusion from the synagogue, carried with it a prohibition to all other Jews of any intercourse with the individual, and was often proclaimed with sound of trumpet. The third, *shammatha* or *anathema maranatha* (see 1 Cor. xvi. 22), was exclusion from the synagogue and privileges of the Jewish church for life, with loss of civil rights, and was accompanied with terrible curses, in which the offender was given over to the judgment of God. In the Christian church, E. has in all ages been practiced, as indeed every society must necessarily have the power of excluding unworthy members and those who refuse to comply with its rules, and the New Testament plainly recognizes and establishes this right in the church. But two different degrees of E. were soon distinguished—the first or lesser, a mere exclusion from the Lord's table and from other privileges of members of the church; the second or greater, pronounced upon obstinate offenders and persons who departed from orthodox doctrine, more solemn and awful, and not so easily capable of being revoked. Penances and public professions of repentance were required; and in Africa and Spain, the absolution of *lapsed* persons (i.e., those who in time of persecution had yielded to the force of temptation, and fallen away from their Christian profession by the crime of actual sacrifice to idols) was forbidden, except at the hour of death, or in cases where martyrs interceded for them. But for a long time, no civil consequences were connected with excommunication. Afterwards, the greater E. was accompanied with loss of political rights, and exclusion from public offices. The power of E. also, which had been at first in the church as a body, gradually passed into the hands of the bishops, and more especially of the popes, who did not scruple to exercise it against entire communities at once. The *capitularies* of Pepin the Less, in the 8th c., ordained that the greater E. should be followed by banishment from the country. The Roman Catholic church pronounces the sentence of E. with many circumstances of terrible solemnity, and it contains a prohibition to all Christian persons of all intercourse with the person excommunicated, and of extending to him even the most ordinary social offices. The latest "examples" made by the pope were Napoleon I. in 1809, and Victor Emmanuel, king of Italy, in 1860; neither of whom, however, was excommunicated by name, the pope having confined himself to a solemn and reiterated publication of the penalties decreed by his predecessors against those who unjustly invaded the territories of the holy see, usurped or violated its rights, or violently impeded their free exercise. Pope Innocent III., in the Lateran council (1215), declared that E. put an end to all civil rights and dignities, and to the possession of any property. The E. of a sovereign was regarded as freeing subjects from their allegiance, and in the year 1102, this sentence was pronounced against the emperor Henry IV., an example which subsequent popes likewise ventured to follow. But the fearful weapons with which the popes armed themselves in this power of E., were rendered much less effective through their incautious employment, the evident worldly motives by which it was sometimes governed, and the excommunications which rival popes hurled against each other during the time of the great papal schism. The Greek church also makes use of E., and every year at Constantinople, on a certain Sunday, the greater ban is pronounced against the Roman Catholic church.—The reformers retained only that power of E. which appeared to them to be inherent in the constitution of the Christian society, and to be sanctioned by the word of God; nor have any civil consequences been generally connected with it in Protestant countries. To connect such consequences with E. in any measure whatever, is certainly inconsistent with the principles of the reformation. Nevertheless, in England, until the 53d of Geo. III. c. 127, and in Ireland, until the 54th, c. 68, persons excommunicated were debarred from bringing or maintaining actions, from serving as jurymen, from appearing as witnesses in any cause, and from practicing as attorneys in any of the courts of the realm. All these disabili-

ties were removed by the statutes above named; and the excommunicated were declared no longer liable to any penalty, except "such imprisonment, not exceeding six months, as the court pronouncing or declaring such person excommunicate shall direct."

In the Roman Catholic church, the power of excommunicating is held to reside, not in the congregation, but in the bishop; and this is believed to be in exact accordance with the remarkable proceeding commemorated in the First Epistle of St. Paul to the Corinthians (1 Cor. v. 3-5), and with all the earliest recorded examples of its exercise. Like all the other powers of the episcopate, it is held to belong, in an especial and eminent degree, to the Roman bishop as primate of the church; but it is by no means believed to belong to him exclusively, nor has such exclusive right ever been claimed by the bishops of Rome. On the contrary, bishops within their sees, archbishops while exercising visitatorial jurisdiction, heads of religious orders within their own communities, all possess the power to issue E., not only by the ancient law of the church, but also by the most modern discipline. As to the prohibition of intercourse with the excommunicated, a wide distinction is made between those who are called "tolerated" and those who are "not tolerated." Only in the case of the latter (a case extremely rare, and confined to heresiarchs, and other signal offenders against the faith or public order of the church) is the ancient and scriptural prohibition of intercourse enforced. With the "tolerated," since the celebrated decree of Pope Martin V. in the council of Constance, the faithful are permitted to maintain the ordinary intercourse. It is a mistake, likewise, to ascribe to Catholics the doctrine "that excommunication may be pronounced against the dead." The contrary is expressly laid down by all canonists (Liguori, *Theologia Moralis*, lib. vii. n. 13, 1). In the cases in which this is said to have been done, the supposed "excommunication of the dead" was merely a declaration that the deceased individual had, *while living*, been guilty of some crime to which *excommunication is attached by the church laws*. Catholic writers, moreover, explain that the civil effects of E. in the mediæval period—such as incapacity to exercise political rights, and even forfeiture of the allegiance of subjects—were annexed thereunto by the civil law itself, or at least by a common international understanding in that age. Examples are alleged in the law of Spain, as laid down in the sixth council of Toledo—a mixed civil and ecclesiastical congress—(638); in the law of France, as admitted by Charles le Chauve (859); in the Saxon and in the Swabian codes, and even in the English laws of Edward the Confessor; all which, and many similar laws, proceed on the great general principle of these mediæval monarchies, viz., that orthodoxy and communion with the holy see were a necessary condition of the tenure of supreme civil power; just as by the 1 Will. and Mary, s. 2, c. 2, profession of Protestantism is made the condition of succession to the throne of England. Hence, it is argued, the mediæval popes, in excommunicating sovereigns and declaring their subjects released from allegiance, did but declare what was, by the public law of the period, the *civil* effect of the exercise of what in them was a *spiritual* authority.

By the discipline of the Roman Catholic church, kings or queens, and their children, are not included in any general sentence of E., unless they be specially named.

EXCRETION. See SECRETION.

EXE, a river of the s.w. of England, rises in Exmoor, in the w. of Somersetshire, and flows 19 m. s.e. to the borders of Devonshire, and then 35 m. s. through the e. part of that co. into the English Channel at Exmouth.

EXECUTION, CRIMINAL. See CAPITAL PUNISHMENT.

EXECUTION, MILITARY AND NAVAL, usually takes place by hanging or shooting, according to the rank of the offender and the nature of the offense. In some rare instances, blowing from the mouth of a gun has been resorted to. For particulars of the acts for which death is awarded, see PUNISHMENTS, MILITARY AND NAVAL, and MUTINY ACT.

EXECUTION ON CIVIL PROCESS is the method whereby the English high court enforces its judgment on the person or estate of those against whom judgment has been given.

In the United States execution is the writ which directs and authorizes the officer to carry into effect the final judgment or decree of a court upon the person or estate against whom judgment has been given. It is usually, though not always, a writ for the recovery of money for debt or damages out of the estate of a defendant. Sometimes it is a writ for a defendant upon a judgment in replevin, for a return of goods with damages; and sometimes a writ for the recovery of costs only. An execution on civil process may be taken out as soon as judgment is pronounced, even before it is recorded. The execution, unless otherwise specially provided by statute, or unless a writ of error or some agreement of the parties be interposed, must be taken out within a year and a day from the time the judgment was signed. After that time execution cannot issue unless a *fieri facias*, or *capias ad satisfaciendum*, was previously sued out. The writ is directed to the sheriff, or in case of his disqualification by interest or otherwise, to the coroner, who becomes responsible for its execution, and is liable for damages if he neglect his duty. He is authorized to sell the personal property of the defendant at auction, and apply the proceeds to the satisfaction of the judgment and the costs and charges of the proceedings; and if there be a surplus, it must be paid to the defendant. In general, lands are not subject to execution; but, after a levy has

been made under the *fiery facias*, they must be appraised by the sheriff's jury and delivered to the plaintiff at the valuation until the debt is paid out of the profits. Exemption is made of certain property from execution for debt, as, for instance, household furniture, necessary provisions and fuel for the use of the family, necessary wearing apparel, bedding, tools of trade, books, pictures, etc., and a homestead of a certain value. The laws of the several states in respect to such exemptions are not uniform in all particulars.

EXECUTION OF CRIMINALS. See CAPITAL PUNISHMENT. Executions took place publicly in the United Kingdom till 1860, when it was by an act of parliament made law that all executions should take place within the precincts of a prison, in the sight of certain officials, newspaper reporters, and others invited to be present. The United States, Bavaria, and the colony of Victoria had previously adopted this method. The lack of that terror with which public executions were supposed to strike the multitude is, by this private mode of procedure, held to be more than compensated by the prevention of what was a brutalizing public spectacle. In London, executions took place for the most part at Tyburn until 1783, when a scaffold erected in front of Newgate prison became the common place of execution. "The gallows was built with three cross-beams for as many rows of sufferers; and between Feb. and Dec., 1785, ninety-six persons suffered by the 'new drop,' substituted for the cart. About 1786, here was the last execution, followed by burning the body; when a woman was hung on a low gibbet, and life being extinct, fagots were piled around her and over her head, fire was set to the pile, and the corpse burned to ashes. On one occasion the old mode of execution was renewed: a triangular gallows was set up in the road opposite Green-Arbor court, and the cart was drawn from under the criminal's feet."—*Timbs' Curiosities of London*. To render executions more impressive, they were in some cases ordered to take place near the scene of guilt. About forty years ago, two men were hanged at Bishopbriggs, near Glasgow, in sight of the scene of a murder they had committed. The ordinary place of execution in most towns in Great Britain and Ireland is outside the prison. At Edinburgh, executions took place chiefly in the Grassmarket, until 1784, when they were transferred to a platform at the w. end of the Tolbooth, a building removed in 1817. The interval between sentence and execution is about three weeks, the nature of the crime not making any difference in this respect. In all parts of the British empire, the convict under sentence of death is allowed to make choice of the spiritual adviser who shall attend on him; and generally, everything that humanity can suggest is done to assuage the bitterness of his fate. At one time, the bodies of murderers after execution were, in terms of their sentence, delivered to professors of anatomy for dissection; and it would appear that in some instances the mangled corpse was made a kind of public show. Such took place on the execution of earl Ferrers, 1760. The body having been conveyed from Tyburn in his lordship's landau-and-six to Surgeons' Hall, was, after being disemboweled and laid open in the neck and breast, exposed to public view in a first-floor room. A print of the time depicts this odious exhibition. The ordering of the bodies to be dissected, having led to great abuse, was abolished in 1832; since this period the bodies of executed murderers are buried within the precincts of the prison, and the bodies of other malefactors are given to their friends. It was also at one time customary to hang the bodies of certain malefactors in chains after execution—as, for example, the bodies of pirates were so hung on the banks of the Thames—but this usage, revolting to public feeling, is likewise abandoned. From the improved state of the criminal law, death-sentences are now of comparatively rare occurrence, and still more rarely are such sentences executed, for, except in cases of deliberate and aggravated murder, the extreme sentence of the law is now usually commuted by the crown into penal servitude for life. The secretary of state for the home department, however, exercises his power in this respect with much care and discretion; and the element of arbitrariness, which might be supposed to spring from differences of temper in different home secretaries, is very seldom obvious.

A great change took place in the public attendance at executions before they were discontinued. Formerly, persons belonging to the higher and middle ranks were habitually present at these dismal exhibitions; many hiring windows at a considerable sum for the occasion. Literature furnishes us with various instances of persons of cultivated mind attending regularly from a morbid love of the spectacle. George Selwyn was fond of seeing executions. His friend Gilly Williams, writing to him of the condemnation of John Wesket (Jan. 9, 1765) for robbing the house of his master, the earl of Harrington, says: "Harrington's porter was condemned yesterday. Cadogan and I have already bespoke places at the Brazier's. I presume we shall have your honor's company, if your stomach is not too squeamish for a single swim."—*Selwyn's Correspondence*, vol. i. p. 323. The earl of Carlisle, writing to Selwyn, speaks of having attended the execution of Hackman, a murderer, April 19, 1779.—*Ibid.*, vol. iv. p. 35. James Boswell, the biographer of Johnson, had a passion for seeing executions, and even for accompanying criminals to the gallows. He was indulged with a seat in the mourning coach to Tyburn, along with the above-named Hackman, the ordinary of Newgate, and sheriff's officer. Visiting Johnson on the 23d of June, 1784, he mentions

that he has just come from the shocking sight of fifteen men hanged at Newgate. Boswell's *Johnson*, vol. viii. p. 331, Croker's edition. At public executions there were to the last considerable crowds, but they consisted chiefly of the lowest of the population. During the excesses of the French revolution, the executions in Paris were enjoyed as a spectacle by crowds of female Jacobins. From the circumstance of these furies employing themselves with knitting needles while attending daily at the scaffold, they became familiarly known as the *tricoteuses* (knitters). Some further information concerning executions will be found in CALCRAFT; CAPITAL PUNISHMENT; DRAWING AND QUARTERING; DROWNING; ELECTRICITY, DEATH CURRENT OF; FOSSA ET FURCA; GUILLOTINE; HANGING; MAIDEN; MURDER; NEWGATE; PARRICIDE; PEINE FORTE ET DURE; TREASON; TYBURN; WHEEL, BREAKING ON THE.

EXECUTION OF DEED, the performance of the ceremonies required by law in order to make a deed binding and effectual. These ceremonies in England consist in signing, sealing, and delivering. According to the ancient common law of England, signature was not necessary to a deed. By 29 Car. II. c. 3 (statute of frauds), signing was required for almost all deeds. But it is still a question which has not been positively decided whether, when a seal is used, it is necessary that the parties should sign. When a party, from any cause, is unable to write, it is usual for him to place his mark in the place of signature. But a mark is unnecessary, and signature by another, at request of the party, is enough. Sealing is the most ancient form of authentication of deeds. In England, deeds are technically known as deeds under seal. A seal is absolutely essential to the validity of an English deed, but any species of seal is sufficient, and in practice a common wafer is usually appended. Delivery is the third requisite to authenticate a deed. Delivery may be made either to the grantee or to another person for him. In the former case, the deed becomes absolute; in the latter, it is called an *escrow*, and does not acquire its full effect till the conditions are fulfilled. Witnesses are not absolutely required to a deed in England, but in practice it is usual that one witness should attest. Before execution, a deed must be read, if required, by a party to it; and if not read, it is void as to the party requesting. Where a person is ordered in chancery to execute a deed or other instrument, and is in prison for failure to comply with the order, the court may make an order that the instrument be executed by the officer of the court; and the execution having been so made, the instrument is equally valid as if signed by the party. The execution of wills in England is regulated by 7 Will. IV. and 1 Vict. c. 26. By this statute it is required that every will shall be signed at the foot or end by the testator in presence of two witnesses. See WILL.

In Scotland, sealing was formerly an essential requisite for execution; but that practice was by 1584 c. 4 dispensed with in regard to registered deeds, and has long fallen into disuse. The solemnities of execution are now regulated by the old acts 1540 c. 117, and 1681 c. 5. By the former of these acts, the signature of the maker of the deed is required, and by the latter, the presence of two witnesses is made essential. In order to a valid execution of a deed or will in Scotland, it is necessary that the maker should sign in the presence of two witnesses, or should in their presence acknowledge his signature, and that the witnesses should then sign their own names, writing after them the word "witness." In case the maker of the deed cannot write, the deed is signed in his presence by two notaries, in presence of four witnesses. But in case of a will, one notary and two witnesses are sufficient. A deed thus witnessed is received as conclusive proof of the facts against the maker. Subscription by initials has been permitted in Scotland. But this mode of execution is irregular, and where it has been adopted, proof has been required that *de facto* the signature was so made. There is one exception to the rule that witnesses must attest the signature—viz., that of a deed or other instrument the whole or the essential parts of which are holograph, i.e., in the testator's handwriting, being valid without witnesses. Bills and promissory notes, receipts, and mercantile accounts do not require to be holograph or attested.

Similarly, in the United States a deed is executed when it is signed, sealed, and delivered; but to make it good against a subsequent purchaser it must be acknowledged before a magistrate and recorded by the officer appointed for that purpose. In some states two witnesses to a deed are required; in others, one witness is sufficient; in others still, the acknowledgment before a magistrate makes any witness unnecessary.

EXECUTIONER, the official who inflicts capital punishment. In England, it is the province of the sheriff to perform this as well as every other ministerial duty enjoined by the criminal courts, but practically he acts by his servants or officers, and he only attends to see the law properly carried out. In royal burghs in Scotland, this duty is imposed on the civic magistracy, one of whom attends for the purpose. In times happily bygone, so numerous were the public executions, that almost every county and town had its E., as an acknowledged officer of justice, with a salary for his subsistence. Yet, we learn that on certain occasions, so odious and so onerous was the duty to be performed, that a special E. was employed. Such was the case at the execution of Charles I. The task of putting this unfortunate monarch to death is well known to have been performed by two men, who, from a dread probably of the vengeance of the royalists, had concealed their faces under visors. In consequence of the mystery thus assumed, public curiosity was much excited, and several persons fell under the suspicion of having been concerned in the bloody deed; rumor even went so far as to

decide who was the wielder of the ax, and who held up the head. It cannot be said, however, that any certainty was ever arrived at on the subject. See *Chambers's Edinburgh Journal*, first series, vol. iv. p. 317.

Like many other offices, that of E. seems to have been at one time hereditary in England. Shakespeare, in *Coriolanus* (act ii. scene 1), makes "Menenius," one of the characters in the play, speak of "hereditary hangmen." In several German states, the office of headman is said to have been also hereditary; certain families being thus, as it were, condemned to perpetual infamy. The last headman of the Tower of London died in 1861. The office was latterly a mere sinecure, and has not been filled up. In some parts of England the office was annexed to other posts; for instance, the porter of the city of Canterbury was E. for the co. of Kent, in the time of Henry II. and Henry III., for which he had an allowance of 20s. per annum from the sheriff, who was reimbursed by the exchequer. The sum of thirteenpence-halfpenny was long popularly spoken of as "hangman's wages;" such sum, equal to a merk Scots, being the fee at one time paid to the E. when he officiated. In the 17th c., this sum, small as it now appears, was considerably above the wages of a skilled mechanic.

From Gregory Brandon, the London E. in the reign of James I., the name Gregory was employed as a familiar designation for executioners for a considerable period. Brandon had the address to procure a coat-armorial from the college of heralds, and became an esquire by virtue of his office. One of his successors was named Dun, or "Squire Dun," as he was called. Dun is referred to in Butler's *Ghosts*, published in 1682:

For you yourself to act "Squire Dun,"
Such ignominy ne'er saw the sun.

He was succeeded about the above year by John or Jack Ketch, commemorated by Dryden (*Epilogue to the Duke of Guise*), and his name has since been synonymous with hangman.—Cunningham's *Handbook of London*, article Tyburn.

Executioners have, in some instances, come to trouble. John Price, the London E., was executed 31st May, 1718, for murder. In the account of him, it is stated that one day, on returning from Tyburn, he was arrested for a debt, which he discharged by a small sum in his pocket, along with the proceeds of the clothes of three felons he had just executed.—*Old Bailey Chronicle*, i. p. 147. If this work can be credited, the E. was about the same time arrested while accompanying John Meff, a criminal, to Tyburn. This arrest, which is amusingly depicted in an engraving, stayed the execution of Meff; being conducted back to Newgate, his sentence was commuted to transportation for 7 years, but having returned to England before the period expired, he was taken and executed. On the 24th May, 1736, the E., on returning from Tyburn, after executing five felons, picked the pocket of a woman of 3s. 6d. (Hone's *Every-Day Book*, ii. p. 695), but what was his punishment is not related. In 1682, Alexander Cockburn, hangman of Edinburgh, was executed for the murder of a bedesman, or privileged mendicant. Early in the 18th c., the E. of Edinburgh was John Dalglish, who acted at the execution of Wilson the smuggler in 1736, and is alluded to in the *Heart of Mid-Lothian*. It was he who also officiated at the execution of the celebrated Maggie Dickson, a woman condemned in 1738 for infanticide, but who came to life again after enduring the sentence of the law, and lived unmolested for years afterwards, as a hawker of salt in the streets of Edinburgh. It is said of Dalglish, that, in whipping a criminal, he made a point of laying on the lash "according to his conscience," which showed him to have been a most considerate executioner. John High, or Heich, accepted the office of Edinburgh E. in 1784, in order to escape punishment for stealing poultry; he died in 1817. See *Traditions of Edinburgh*, by R. Chambers. The emoluments of the Edinburgh E. at one time comprehended a recompense in kind in the markets of the city—viz., a *lock* or handful, and a *gowpen* or double handful, of meal from each sack; hence he received the designation of *lockman*. These emoluments were latterly commuted into a regular salary of 12s. per week, besides a free house, and a special fee of £1 11s. 6d. at each execution; from the exchequer the E. also received a small annual allowance as deemster (q. v.). The last of the Edinburgh executioners was John Scott, whom it was customary to confine in jail for 8 days previous to an execution, in order to insure his attendance; the expenses incurred by him during one of these periods of seclusion being, as we find, £1 2s. 6d., which sum was discharged by the city. Scott was killed by a malicious assault in 1847. Since this period, Edinburgh has had no regular hangman, but, like all other places in Great Britain, depends on the London E., who is hired for the occasion. This personage, until lately, was the well-known William Calcraft. For an execution at Edinburgh in 1854, Calcraft's fee and expenses amounted to £33 14s.; his assistant received £5 5s.; and for taking charge of both, the city criminal officers were paid £1 1s.; total expenses for the execution, £40, independently of the cost of erecting the scaffold. In 1815, the magistrates of Glasgow entered into an arrangement by stamped indenture with Thomas Young, who engaged to act as E. at a recompense of £1 per week, a free house, with coal and candles, a pair of shoes and stockings once a year, and a fee of a guinea at each execution. At Young's death in 1837, his successor, John Murdoch, was recompensed differently. He was paid £1 per month by way of retainer, and the sum of £10 for an execution. After his death Calcraft officiated, he in turn having been succeeded by Marwood. Besides the usual fees, execu-

tioners have from early times claimed the clothes of those who suffer, as a perquisite of office.

The most noted E. of Paris was the late M. Sanson, who officiated at the mournful death-scene of Louis XVI., and is said to have possessed acquirements and feelings not to be expected from one of his degrading profession. He was latterly assisted by his son, M. Henri Sanson. See *Memoirs of the Sansons* (1875). The Parisian E. is familiarly styled "Monsieur de Paris."

No professional E. is employed at capital punishments in the United States. There the sentence is executed by the sheriff, with the assistance of an under-jailer; this last official performing the fatal toilet of the criminal, while the sheriff, by a movement affecting the drop, puts him to death in virtue of the sentence and the law of the state. This seems an advance on the practice in England, where, however, it could not be introduced, for the simple reason that no one fit for the rank of sheriff or magistrate would accept of office with an obligation to perform the duty of E. in prison. The military E. attached to an army is styled provost-marshal (q.v.).

EXECUTIVE. See GOVERNMENT.

EXECUTIVE DEPARTMENT, the branch of the government to which is confided the duty of executing the laws; in distinction from the legislative department which enacts, and the judicial department which expounds them. In the U. S. government, the chief executive officer is the president; in the several states, the governors thereof. The secretaries of state, treasury, interior, war, and the navy, with the postmaster-general, and the attorney-general, are officers of the executive department under direction of the president. The law does not oblige him to consult them, but the custom has made them his counselors and advisers. In the different departments are numerous subordinate executive officers, known as assistant-secretaries, clerks, examiners, solicitors, auditors, controllers, commissioners, deputy-commissioners, directors, chiefs, superintendents, etc. There are also collectors of internal revenue (in districts), and collectors and surveyors of customs (in districts).

EXECUTOR, IN ENGLAND, the person to whom the execution of a last will and testament of personal estate is by testamentary appointment confided (Williams on *Executors*, 197). The appointing by will of an E., without giving any legacy or appointing anything to be done by him, is sufficient to make a will. The appointment of an E. can only be by a will, the person who takes charge of the estate of an intestate being called an administrator (q.v.). The appointment may be either express or constructive, i.e., gathered from the general terms of the will. An early duty of an E. is to take probate (q.v.) of the will. He derives his title solely from the will; the estate vests in him from the death of the testator, at which time his responsibility begins, and from which time he may enter upon all the duties of managing the estate. But his position will not be recognized as suitor in any court until he has taken probate. The whole personal estate vests in the E., and if the testator has made no disposition of the residue, it devolves, by common law and equity, upon the executor. The court, in some cases only, will endeavor so far to carry out the intentions of the testator as not to give the beneficial interest to the E., where there appears from the will a necessary implication that he should not receive it. By 21 Henry VIII. c. 5, an E. is bound to prepare an inventory of the personal estate. This, if required, must be produced. An E. may raise actions in respect to the estate in his charge; and generally it may be said that his powers, duties, and liabilities are commensurate with those of the deceased. He may enter the house of the deceased to remove the personal property. The first claims to be discharged are those of the funeral and the expenses of probate. He must then pay the debts; and he is responsible for paying them in due order, so that those having a legal preference shall first be discharged. An E. is not bound to accept the office; but if he administers, he cannot then renounce the executorship without cause. On the death of an E. the office does not pass to his executor.

An E. to a will in Scotland is called a testamentary E., to distinguish him from the next of kin, who are styled executors. The term E. is given to all who manage the estate of a deceased, whether appointed by will or by authority of the court. The former are called executors nominate; the latter, executors dative. All executors must, before entering upon their duties, obtain *confirmation* (q.v.) from the commissary court. This is equivalent to probate in England. But in Scotland, no right vests in the E. until after confirmation, except a title to sue, being exactly the reverse of the English rule. An E. acting without confirmation is called a *vitious intromitter* (q.v.). Executors must, on entering upon their office, exhibit a full inventory of the whole movable estate of the deceased. An E. is only liable to the extent of the inventory. He is not bound to pay interest on the funds in his hands unless they bore interest before confirmation, or unless he is guilty of undue delay in administering the estate. He is not bound to pay the debts for six months after the death of the deceased. But, as in England, the expenses of the funeral and confirmation are entitled to immediate payment. Servants' wages and a year's house-rent have also a preferable claim. An E. is entitled to claim one third of the *dead's part*, after deducting debts. But should he receive a legacy, he is bound to impute that towards payment of his claim.

An E. in the U. S. is a person to whom another man has committed the execution of his last will and testament. He may decline to act if he choose, in which case the court will appoint an administrator. But if he accept and enter upon the trust he cannot resign it without reason. In general, any person capable of making a contract may be an executor. His duties are to bury the deceased in a manner suitable to the estate left behind, to prove the will, take possession of the property of the testator, make an inventory of the same, collect the assets, and pay the debts and legacies. For this the law gives him all the powers of the testator. Generally an executor is required to give bonds for the faithful discharge of his duties.

EXECUTORS, in Scotland, the heirs in *mobilibus* of a person deceased. They are the whole next of kin in the nearest degree in blood; but where the heir to the heritage is one of the nearest of kin (e.g., the oldest son), he is not entitled to share in the movables without collation (q.v.). The order of succession among executors is first descendants, then collaterals, or brothers and sisters, and their children; and, lastly, ascendants, i.e., the father and those claiming through him. But the mother and her family, till recently, were not allowed to succeed to her own child *ab intestato*. This harsh rule was so strictly carried out, that where there were no relations by the father, the crown succeeded as *ultimus hæres*, to the exclusion of the mother.

By 18 Vict. c. 23, the law of succession to movables has been in some degree altered. On the death of an intestate leaving no issue, his father, if he survive, is entitled to take one-half of the movable estate, in preference to brothers and sisters. If the father be dead, the mother takes a third. No further provision, however, is made for the mother in case she is the only surviving relative. The result is, therefore, that the other two-thirds would still go to the crown. See SUCCESSION, MOVABLES.

EXECUTORY DEVISE, in statute law, is such a limitation of a future estate or interest in lands or chattels (though in the case of chattels it is more properly a bequest) as the law admits in the case of a will, though contrary to the rules of limitation in conveyances at common law (Blackstone, *Comm.* ii. 334). By common law, a freehold cannot be limited on a freehold, as an estate to A and his heirs; but if he die before he attain the age of 21, then to B and his heirs. Nor can an estate be given to commence at a time uncertain, as to A when he returns from Rome. But though these limitations would be void in a deed, common law will sustain them as executory devises. This form of limitation is restrained by the law against perpetuities (q.v.), which requires that the estate must take effect within a life or lives in being and 21 years after. The law will not interpret a limitation as an E. D., if it can be otherwise sustained. Whenever, therefore, a future interest in land is so devised as to fall within the rules laid down for the limitation of contingent remainders, such devise will be construed as a contingent remainder, and not as an executory devise (Cruise, *Digest*, vi. 369). An E. D., unlike a remainder, cannot be defeated by any act of the first taker or devisee; when, therefore, an absolute power of disposition is in the first taker, the limitation over is not an executory devise. Within the period allowed for these estates, an E. D. constitutes a species of estate tail; and for this purpose, it is frequently used in America.

EXEGESIS (from Gr. *ex*, out of, and *hēgeomai*, I lead) properly signifies the exposition or interpretation of any writings, but is almost exclusively employed in connection with the interpretation of sacred Scripture, to which, therefore, the subjoined remarks specially apply. The expositor or interpreter is called an *exegete*. To interpret a writing, means to ascertain thoroughly and fundamentally what are the conceptions and thoughts which the author designs to express by the words he has used. For this purpose, it is necessary, in regard to books written in a foreign language, that the exegete should know well, first, the precise signification of the words and idioms employed by the writer. This is termed *grammatico-philological* exegesis. In the next place, he must be acquainted with the things denoted by these words, and also with the history, antiquities, and modes of thought of the nation. This is termed *historico-antiquarian* exegesis. Both together constitute *grammatico-historical* exegesis. When only an exposition of the system of thought contained in a writing is sought after, this is termed *doctrinal* or *dogmatic* E.; while the investigation of a secret sense, other than that literally conveyed by the words of a writing, is termed *allegorical* exegesis. But if a writing is regarded from a practical point of view, and in reference to its bearing upon life and manners, the exposition is termed *moral* exegesis. The complete and coherent E. of a writing forms what is called a *commentary*, but, if restricted to certain difficult words or knotty points, the elucidations are termed *scholia*. The scientific exhibition of the rules and means of E. is called *hermeneutics* (q.v.). In the earliest ages of the Christian church, the allegorical method of E. prevailed. By the Alexandrian school in particular, it was greatly abused. Origen, however, the greatest of this school, deserves high credit for endeavoring to secure a basis for grammatical E., by a sharp separation of the literal, the moral, and the mystical sense of Scripture. Besides the Alexandrian school, the Syrian historico-exegetic school had many adherents in the east. Among these may be mentioned Cyril of Jerusalem, Ephraem Syrus, John Chrysostom, and Theodorus of Mopsuestia. First, towards the end of the 4th, and during the 5th centuries, a narrowing of the principle of the free interpretation of Scripture begins to be

observable, through the rapid development of monkery and the hierarchical system; in consequence of which, the importance of the classic writers was undervalued, and the study of them ultimately abandoned in the western church, while a feeling of superstitious reverence, wholly unintelligent and unscriptural, grew up for the letter of the "Word," and E., if employed at all, was employed simply to bolster up preconceived views. By and by, independent E. was supplanted by the well-known *Catenæ*, consisting of expositions of books of Scripture strung together from the writings of the older church fathers. In the east, the first of these was got up by Procopius, 520 A.D.; in the west, by Primasius, 550 A.D. Although much was done for the E. of the Old Testament by eminent Jewish scholars, such as Solomon, Jarchi, Aben-Esra, and David Kimchi, Christian theologians for the most part, knowing only the text of the Vulgate, stuck, during the dark ages, to the interpretations of the fathers. First in the 12th, 13th, and 14th centuries, efforts were made by individual scholastics, especially by Abelard, St. Bernard of Clairvaux, Thomas Aquinas, and Nicholas of Lyra, to reintroduce something like a grammatico-historical E. of Scripture. But it was mainly to the great revival of letters in the 15th c., and the humanistic scholars whom it produced, such as Laurentius Valla, Erasmus, etc., that an advance in E. was owing. The Complutensian polyglott also exercised a great and beneficial influence. Shortly after, the reformation gave an impulse to E., so powerful, that it is felt at the present day; and, indeed, its effect is far more visible in the recent biblical criticism of Germany than it was in the days of Luther himself. The desire for the unfettered E. of Scripture strongly animated the reformers, but, in fact, the long black night of ignorance—known as the dark and middle ages—has influenced them too, and disqualified them for framing at once a comprehensive exegetical science. It required a couple of centuries to recover from the effects of mediæval ignorance. The more important Lutheran exegetes are: Luther, Melancthon, Brenz, Joach. Camerarius, Strigel, Chemnitz, etc.; of the reformed or Calvinistic school may be mentioned Calvin, Zwingli, Ecclampadius, Bucer, Beza, Bullinger, Grotius, Clericus, etc.; and of the Roman Catholics, especially Paul Sarpi. During the 17th c., the E. of Scripture was for the most part at a stand still, but about the middle of the 18th c. it suddenly revived. This revival was due principally to Joh. Aug. Ernesti (q.v.), and J. Sal. Semler (q.v.), who established new principles of criticism and hermeneutics, through which grammatico-historical E. once more began to make its appearance. The labors of Wetstein and Kennicott in regard to biblical MSS. were of immense service. Since their day, on to the present, criticism has been constantly at work on the writings of the Old and New Testament. Cognate languages have been more and more profoundly studied; the antiquities of the east, of Egypt, Assyria, Arabia, and other countries, have been investigated, and brought to bear on the subject; the manners and customs which prevail in these lands, and which, in some of them, have prevailed from time immemorial; the laws that determine the growth of civilization in nations, and enable us to enter into and comprehend the condition of mind peculiar to races in a primitive stage of development, and to appreciate their modes of thought, and to weigh the value of their literary and religious records—all these have received, and are still receiving careful attention at the hands of numerous scholars, so that it is not too much to say that we are at the present day better fitted—so far as outward helps go—to understand the real meaning of Scripture, than those who have lived at any other period subsequent to its composition. Among the eminent names in the recent development of biblical E. are F. A. Wolf, J. Dav. Michaelis, Eichhorn, Gesenius, Wahl, Bretschneider, Winer, Rosenmüller, Hitzig, Hirzel, Ewald, Umbreit, De Wette, Knobel, Lücke, Paulus, Meyer, Olshausen, Hengstenberg, etc. The influence of the *grammatico-critical*, and *critico-historical* E. of modern Germany, is only beginning to make itself felt in this country. The most important contributions to the science recently made by British scholars, are those by Conybeare and Howson, Alford, Stanley, Jowett, Ellicott, etc.

EXELMANS, REMY JOSEPH ISIDORE, Comte, a distinguished French general, b. at Bar-le-duc, 13th Nov., 1775. He entered the army in 1791, was promoted to the rank of capt. in 1799, served with distinction in the campaign of Naples under Macdonald and Championnet, and in 1801 was attached as aide-de-camp to the staff of Murat. In 1808, while with Murat in Spain, he was arrested, and sent to England, where he remained a prisoner for three years. He was with Napoleon in the Russian campaign in 1812, for his brilliant conduct in which the emperor created him gen. of division, Sept. 8th of the same year. E. seems to have been equally esteemed under every successive government. On the fall of Napoleon, he was for some time banished from France, but was permitted to return in 1819. In 1831, Louis Philippe restored his titles and rank. Louis Napoleon named him grand chancellor of the Legion of Honor, and on Mar. 11, 1851, raised him to the dignity of *maréchal de France*. On the 21st July, 1852, E. had a bad fall from his horse, from the effects of which he expired on the following night.

EXERCISE, a very important element of medical regimen, both in the preservation of health and in the cure of disease. To preserve all the functions of the body in healthy action, it is necessary to secure their due and regular action or E.; to allow of complete inaction of any part or function, is to initiate disease, and probably even

structural change, or atrophy. Hence the development of the muscular system, of the secretions, and even of the mind and its organ, the brain, require the more or less regular use of E., either in the form of productive and useful work, or by means of artificially devised methods calculated to serve a like purpose in regard to the economy. Thus, scholastic education is exercise for the mind; gymnastics (q.v.), for the body. Both these means enter largely into enlightened medical practice, though they are often too much neglected. E., to be beneficial, must be attended with rest, to allow the tissues which are worn away during vital action to be restored.

EXETER (the *Civ-Isce* of the Britons, the *Isca Damnoniorum* of the Romans, *Exan-cestre* of the Saxons), a city, episcopal see, separate county, parliamentary and municipal borough, and river-port, in the s.e. of Devonshire, and the capital of that county. It lies on an acclivity on the left bank of the Exe, 10 m. n.w. of its mouth, 170 m. w.s.w. of London, and 73 m. s.w. of Bristol. It is on the whole well built and clean, and has two main lines of street meeting near the centre. There are some fine squares and terraces. The guild-hall has a singular portico, added in 1593, and projecting into the street. It was restored, with considerable regard to artistic effect, in 1864. E. cathedral, a cruciform structure, magnificent in its ornamentation, was erected 1112-1478. In one of its towers is the Great Tom of E. or Peter's bell, 12,500 lbs. weight, and a large curious antique clock. It measures 408 feet by 76, but across the transepts is 140 feet wide. Being only 66 feet high, it gives the impression of a long, low building. It has massive towers on the sides, which are in the original Norman style of architecture, and which are 130 feet high. It contains a fine choir screen, dating from the early part of the 14th century. The chapter house has several thousand valuable manuscripts. Among the other buildings are St. John's hospital, founded in the reign of Henry III.; the Albert Memorial Museum, opened in 1868; a post office, lunatic asylum, and almshouses. E. has a large floating ship-basin, and a ship-canal extending to Topsham. E. has magnificent nurseries, and exports dairy, farm, and orchard produce from a neighborhood rich in such products. The town sends one member to parliament. E. was anciently the chief residence of the West Saxon kings. E. bishopric, fixed here in 1050 by Edward the confessor, includes Devon and Cornwall, 23 deaneries and 588 benefices. The city was formerly surrounded with walls and strongly fortified. On a height to the n. of E. are the ruins of Rougemont castle, built by William I., on the site of one said to be as old as Caesar's time. Many Roman and Greek coins have been found in E., besides tessellated pavements, fragments of columns, and small bronze statues. Pop. 1891, 37,404.

EXETER, a town, village, and one of the co. seats of Rockingham co., N. H., on Squamscott river and the Boston and Maine railroad; 50 m. n. of Boston. The town is built around the falls, and the chief business is manufacturing, especially cotton, iron and brass goods, machinery, and shoes. Here is the richly endowed Phillips academy, which for generations has had a national repute, founded in 1781 by John Phillips; also the Robinson female seminary, with large endowment, a high school, and several graded schools, public library, churches, state and savings banks, water works, gas lights, and daily and weekly newspapers. The place was settled in 1638 by the Rev. John Wheelwright, an exile from Massachusetts. It suffered greatly in the various Indian wars of the century, and 38 of its citizens died in the continental army. It was the capital of the state during the Revolution. Pop. '90, 4284.

EXETER BOOK, THE, also called the *Exeter Codex*, is a manuscript collection of early English poetry written before the Norman conquest, or, before the period of English literature actually began. The collection was presented to the library of Exeter cathedral during the reign of Edward the Confessor by Bishop Leofric. It contains poems of King Alfred, Caedmon, Alfric, Cynewulf, and some others, besides a number of riddles.

EXETER COLLEGE, Oxford. This college was founded in 1314 by Walter de Stapledon, bishop of Exeter, who removed from Hart Hall to the present site of E. C., a rector, and twelve fellows. In 1404, Edmund Stafford, bishop of Salisbury, added two fellowships, and gave the college its present name. Sir William Petre, in 1565, founded eight more; and in 1636, Charles I. annexed one more for the islands of Jersey and Guernsey. In 1770, Mrs. Sheers left certain rents for the establishment of two fellowships. All these fellowships were originally appropriated to various archdeaconries or counties, especially in the w. of England. A peculiarity in this college was, that the above foundations, though generally called fellowships, were, strictly speaking, only scholarships. Important changes were introduced by the rector and fellows, under the authority of 17 and 18 Vict. c. 81, and approved of by the commissioners appointed to carry out that act. The number of fellowships was reduced to 15—all open without any restriction as to place of birth. The revenues of two fellowships were divided among the rectorship and the 15 fellowships. The remaining 8 fellowships were devoted to the foundation of 22 scholarships; ten open without restriction; ten limited to persons born, or for three years educated in the diocese of Exeter; and two limited to persons born in any of the Channel islands. Several exhibitions also are attached to the college; and there are about 16 benefices in the gift of the society. The number of names on the books is about 750.

EXETER, or **EXON DOMESDAY**. See **DOMESDAY BOOK**.

EXETER HALL, a large proprietary building, on the n. side of the Strand, London, is 131 ft. long, 76 ft. wide, and 45 ft. high. It was completed in 1831, and can contain upwards of 3,000 persons. It is let chiefly for religious assemblies, and is in great request during the "May Meetings" of the several religious societies. It is also let as a concert-room and has been the scene of many great musical fêtes.

EXFOLIATION (Lat. *exfolio*, "I strip of leaves."), signifies in one use of the word, a separation and scaling off, as of a rock or a mineral; in another use it denotes a throwing off a dead from living tissue, as, of a piece of dead bone. See NECROSIS.

EXHAUSTIONS, METHOD OF, is a mode of proving mathematical propositions regarding quantities by continually taking away parts of them. The method was frequently employed by the ancient geometers; its fundamental maxim, as stated by Euclid, being that those quantities are equal whose difference is less than any assignable quantity. Euclid employs the method in Book x. Prop. 1; and it was used by Archimedes to prove that the area of a circle is equal to that of a right-angled triangle whose one leg adjoining the right angle is the radius, and the other the circumference. In this ancient method we may see the rudimentary form of the modern transcendental analysis.

EXHIBITION, INDUSTRIAL (Fr. *Exposition de l'Industrie*). Exhibitions of this kind originated in France, where the first took place in 1798, at the suggestion of the marquis d'Avèze. It was held in the Maison d'Orsay and its grounds; but it appears to have been rather a collection of such objects of French art-manufacture as could be borrowed from their owners, than an assembling together of competing artists and manufacturers, with their respective works. It is, nevertheless, interesting as a historical fact, having been the first of these displays of which we have any clear and authentic record; and its more important effect was to familiarize the French mind with national exhibitions.

In the same year, another exhibition was held in Paris, on a grander scale, and with considerable success. It embraced all kinds of manufactures; whereas that at the Maison d'Orsay was chiefly devoted to those of artistic merit; hence the credit has been claimed for the latter one of being the commencement of industrial exhibitions, certainly, however, without justice or truth.

In consequence of the obvious utility of the exhibitions of 1798, another was held in 1802, under the consulate of Napoleon, with equal success, and thus led to the establishment of triennial exhibitions, which were, with occasional interruptions from political causes, held until the novel idea was originated in Gt. Britain, in 1850, by his royal highness the prince consort, of holding a universal exhibition open to all comers.

That was not, however, the first industrial exhibition held in the United Kingdom. The Royal Dublin society, possibly from the French sympathies of Ireland during the revolution, as early as 1829 adopted the plan of triennial exhibitions, which was several years before any other part of the United Kingdom; they took place in the society's rooms in Dublin. Like the French, however, they at first comprised only specimens of native industry.

In England, the first well-organized exhibitions were those of the Cornish polytechnic society, in which were illustrated the mineral wealth of the co., and its mechanical appliances for mining purposes, etc. These were continued annually without intermission until 1850. Manchester, Birmingham, and Liverpool also held local exhibitions; that of the second town was by far the most important, and is fairly entitled to be considered the prototype of the 1851 exhibition; indeed, it is by no means certain that both did not arise from the same cause—the agitation in favor of a great national exhibition, commenced by his royal highness the prince consort and the society of arts as early as 1848. The Birmingham exhibition was held in 1849.

The Manchester exhibitions were the earliest held in the great English industrial towns, but they, like those which were held in the mechanics' institutes of Liverpool and Leeds, and subsequently in the collegiate institution of Liverpool, had a mixed character, the illustrations of art and manufactures being pretty well mingled with objects of natural history and various other curiosities, for the amusement of the visitors. That of Birmingham, however, was much more completely devoted to the true objects of industrial exhibitions; it was held in the spacious apartments of Bingley hall, and was a great success, especially when it is borne in mind that it was carried out solely by private enterprise. The multitudinous manufactures of that wonderful place were amply illustrated, and a most careful attention was paid to the exhibition of those objects of art which were best calculated to foster the taste of designers, and others, whose duty it was to give refinement to the masses, by gradually improving those objects of necessity and ornament in every-day use.

The first metropolitan movement in favor of holding a national exhibition in Gt. Britain was immediately after the French exposition of 1844, the results of which were so beneficial, that several applications were made to the government requesting that the matter should be officially taken up. The government, however, as usual, proved itself to be simply executive, and did nothing.

In the meantime, the society of arts tried the experiment of holding exhibitions annually in their own building in the Adelphi; but these, though eminently successful, were not sufficient to satisfy those with whom a national exhibition had become a fixed

idea. In 1849, his royal highness devoted himself thoroughly to this object, and made the happy suggestion of throwing open the exhibition to all nations. The plans, too, were suggested for raising the necessary funds and other essential points, and the scheme soon took a tangible form; and it was finally determined by the government to issue a royal commission, which was gazetted Jan. 3, 1850. From this moment the great exhibition was fairly launched. In order to enable the commissioners to enter into contracts, and otherwise incur obligations, it was necessary to procure subscriptions to a guarantee fund. The subscription-list was opened by the queen with £1000. The exhibition took place in a vast structure of iron and glass, called the crystal palace, in Hyde park, London. The edifice, planned by sir Joseph Paxton (q.v.), was opened by her majesty, May 1, 1851. It was 1851 ft. long by 456 ft. broad, and 66 ft. high; the entire area covered being 13 acres. On the ground-floor and galleries there were 8 m. of tables. The glass employed in the structure weighed upwards of 400 tons. The number of exhibitors exceeded 17,000. The exhibition was open 144 days, being closed Oct. 11. The entire number of visitors was 6,170,000, averaging 43,536 per day. The largest number at one time in the building was 109,760, on Oct. 8. The entire money drawn for tickets of admission amounted to £505,107; and after all expenses were defrayed, a balance of £150,000 was left over; so that there was no call on those who subscribed the guarantee fund. Popularly, this great exhibition was properly enough called the world's fair, for it attracted visitors from all parts of the world. When the exhibition was over, the building was cleared away.

The importance of this celebrated exhibition was so obvious, that other countries became anxious to have something of the same kind. An exhibition was held in Cork in 1852; although not of international character, it was the first for which any special structure was erected in Ireland, and deservedly gave great satisfaction. The home manufactures of Ireland were admirably displayed in conjunction with those of other parts of the kingdom. Dublin got up an international exhibition in 1853, and by the princely munificence or Mr. Dargan, was enabled to make an admirable display, in a building of great beauty. The Dublin society added a new feature—high art was associated with industrial art, and a gallery of pictures, the finest ever brought together in Gt. Britain before, was there exhibited with great success. In the same year, a similar exhibition took place in a crystal palace in New York. France, in 1855, repeated the same experiment with immense success; both the industrial and the art collections were such as the world had never seen before. Though wanting the imposing magnitude of the Hyde park building, the contents of the palais de l'industrie, with its detached picture-gallery and its annexe, were of the choicest description, and reflected the highest credit on French taste and skill. Several other continental nations followed with various success. In Europe, it has now taken root, and every country looks upon an exhibition of its industrial resources and productions, from time to time, as a grand necessity which must be met. In 1861, there was an exhibition at Haarlem, in which a vast assemblage of admirably arranged specimens illustrated every industry followed by the most industrious and methodical people of Europe. In Belgium, also, a small industrial exhibition was held in 1861 at Brussels, consisting chiefly, however, of articles of use, in which tasteful design was the chief consideration.

Such is a brief outline of the early history of these exhibitions, which now form a prominent feature in this era of the history of civilization. The fullness of their effects is still to be seen, but, judging of the beneficial effects they have already produced, it is not too much to say, that they appear destined to help most largely in diffusing a love of industry, and a peaceful emulation over the whole globe. Commerce may have its weak points, even its meannesses, but it cannot be denied that few of the occupations of man are more humanizing, or tend more to teach the value of peace and good-will; and if this be conceded, certainly nothing can more assist it than these great gatherings, in which each nation shows its own specialities, and gives to others the ideas which it has accumulated through its centuries of progress in industrial art. Like the social interchange of thought, this interchange of inventive genius brings out new talents; and succeeding generations will reap a rich harvest of results from our industrial exhibitions. To mark the advance in the arts of the interval, and promote manufacturing and commercial activity, an exhibition, on a still greater scale, was arranged to take place at Kensington, London, in 1862; in which were to be comprehended paintings in a high style from all countries. See *Official, Descriptive, and Illustrated Catalogue of the Great Exhibition of 1851* (3 vols.); also *Reports by the Juries* (2 vols.); and the 13 vols. folio, printed by the commissioners.

Since the article on this subject first appeared several international exhibitions have been held—one in 1862 in London; in 1865 in Dublin; in Paris in 1867; in 1873, the great universal exhibition of Vienna; that of Philadelphia in 1876; of Paris, 1889; of Chicago, 1893, etc. That of 1862 was held in a vast brick building, lighted by a roof and two immense cupolas of glass, designed by Capt. Fowke, R.E., and erected on a large space of land acquired by the royal commissioners of the great exhibition of 1851, adjoining the beautiful garden of the horticultural society at South Kensington. The space covered was 1,291,800 sq. ft., or about 17 acres, including some portions of the buildings of the garden, lent by the horticultural society, for refreshment-rooms, etc. Of this vast space, 391,146 sq. ft. were occupied by objects exhibited, besides

284,670 sq. ft. of wall and other vertical space made by internal partitions, etc.; to which must be added 93,220 of horizontal and vertical space occupied by works of art, arranged in one of the most admirably constructed galleries ever designed for such a purpose. The entire cost of this gigantic affair was £321,000. This was secured against all risk of failure by a voluntary guarantee entered into by 1152 gentlemen of all ranks, who pledged themselves in various sums amounting, in the aggregate, to £450,000. Notwithstanding much opposition and ill-feeling, the international exhibition of 1862 proved a great success. Like its predecessor in 1851, it gave a vast impetus to trade generally, and it enabled the public to form correct opinions upon the progress of manufactures, and their shortcomings when compared with others.

The next exhibition of importance was that held in Dublin in 1865, which was originated by a company, whose object was to establish the principle of decennial exhibitions, and, if possible, make this one pay the expense of erecting the magnificent building in which it was held, and thereby form a permanent home for such exhibitions and other useful purposes in future. This building was of brick, covered with stucco, and the roof of glass and iron, light but commodious galleries running entirely round the interior. The whole surface occupied by the structure was 5,700 sq. yards. It was, in every respect, well adapted for the purposes for which it was raised, and had an extensive pleasure-garden nearly surrounding it. The exhibition was successful in everything but its pecuniary results. It was amply patronized both by foreign exhibitors and visitors, and like that of 1862 in London, and the previous ones of Dublin and Paris, it combined fine arts with the manufactures, mining, and other industries.—The year 1867 witnessed, in Paris, the greatest, up to that time, of all international exhibitions, both with respect to its extent, and to the scope of its plan. Its site was on the Champ-de-Mars, the great military parade-ground of Paris, and it occupied the enormous space of 37 acres. It consisted of a large building of an elliptical form, arranged in twelve concentric circles, with a small open central garden. The outer circle was much more lofty and broader than any of the others, was roofed with corrugated iron, and lighted with clerestory windows, and was devoted to machinery of all kinds, and to the processes of manufacture in various branches of industry. Outside this circle were placed practical illustrations of the food department, in the form of restaurants of all nations—the exhibition of specimens of food substances being in small courts within the outer wall, or back to back with the restaurants. The first circle within that for machinery was for metallurgy, chemistry, dyeing, etc.; then followed textile materials, clothing, household furniture, personal ornaments, plate, porcelain, etc.; then matters relating to general and special education. Then came the gallery of fine arts, in which the paintings, sculpture, and other fine-art works of all nations were exhibited; and within this circle, again, was another, in which an archæological collection from each country was displayed, for the purpose of showing the rise and progress of industrial art in every country. This was a novel and most valuable addition, admirably conceived and carried out. Another most important feature in the Paris exhibition was the park, or out-of-door portion, which occupied by far the larger part of the whole space. In this were shown actual examples of the styles of domestic and palatial architecture of most countries, and even the tents of some of the nomad tribes, such as the Kirghis Tartars, and Samoyeds of the Russian empire, the Bedouin Arabs, etc. The beasts of burden of different nations, such as horses, camels, etc., were also shown, and all kinds of civil and military erections of general importance. The exhibition had great and deserved success; it was visited by most of the principal monarchs of the world, and vast multitudes of people. Pecuniarily, however, it did not succeed.

Since the Paris exhibition of 1867, there have been important ones held in Sweden (1868) and in Denmark (1872); at Moscow (1872); Vienna (1873); Philadelphia (1876); Paris (1878); Amsterdam (1883); Calcutta (1884); Antwerp (1885); Edinburgh (1886); Brussels (1888); and the very magnificent exhibition given in Paris in 1889, in the Champ de Mars, for which among other remarkable structures the Eiffel tower was erected, and which was, perhaps, the most successful exhibition that had been held in any country prior to the Columbian Exposition of 1893.

The quasi-international Moscow exhibition of 1872 was organized by the Moscow polytechnic society, and merely patronized by the government. It was, however, on a large scale and admirably managed—its various buildings, etc., completely occupied the Alexandra gardens round two sides of the Kremlin, a length of over two English m., and the great riding-school. In its arrangement the greatest skill was shown, and its classification was the best and most scientific which has ever yet been attempted. Each special group of objects had separate buildings. Thus, for instance, medical science, which was fully represented, had a series of buildings, three model hospitals, besides those in the military department—all fully furnished—dispensaries, a pharmacist's shop, and a garden in which all the medicinal plants were growing; an exhibition of all kinds of surgical instruments and appliances, and a great variety of other matters appertaining to medicine and surgery; a dentist's establishment, with everything appertaining to dentistry, whether to the treatment of natural teeth, or the manufacture of artificial ones; and so on. Should ever a great international exhibition be carried out on the same grandly conceived plan, it will be the greatest educational effort possible.

The two Scandinavian ones in magnitude exceeded those held in Dublin; they were very interesting, and were under good management successful in all respects.

The Vienna exhibition of 1873 far exceeded in magnitude any previous one, and although unfortunate in many respects, was, upon the whole, an event of which Austria has good cause to be proud; and its ultimate results, there is every reason to hope, may show great commercial benefits, as it brought every civilized nation to Vienna, and doubtless will be the means of extending Austrian commerce, by making the general excellence and great variety of Austrian and Hungarian manufactures better known. The main building, which still remains, was the largest that had been constructed, being nearly four times the size of that in which the Paris exhibition of 1867 was held: it consists of a vast gallery or nave, 2,980 ft. in length, in the exact center of which is placed a great central hall, 426 ft. in diameter, covered with a conical iron roof and lantern rising to the height of 160 feet. At each extremity of the main avenue, another gallery, 660 ft. in length, is placed transversely to the chief one, and another of similar length crosses the nave at a distance of 114 ft. from each of these terminal transepts, whilst each of these pairs have their extremities connected by ranges of offices. Sixty-six ft. from the central rotunda on each side is a similar transept connected by two others parallel to the line of the main avenue, and thus forming a square inclosing the rotunda. Ten other transepts cross the main avenue; the height of all the galleries being about 50 feet. Vast as this structure was, it was found insufficient; and numerous halls and other annexes had to be built. The entire extent under roof is said to have exceeded 60 acres. A severe outbreak of cholera, and a deplorable monetary crisis occurring during the exhibition, marred its success.

The next great international exhibition was that of the United States of America, which was held in Philadelphia in 1876, in honor of the centenary anniversary of American independence. The main building was 1876 ft. long, and 464 ft. broad. The machinery-hall was 1400 ft. long, and in all no less than 190 buildings were erected for the purposes of the exhibition. The work of preparation and building occupied 21 months. Between the 10th of May, when the exhibition was inaugurated with elaborate ceremonies, till Nov., it was estimated that no fewer than 8,000,000 paid for admission. Both commercially and in other respects, this memorable enterprise was very successful. See CENTENNIAL EXHIBITION.

The next exhibition in the western hemisphere was that at New Orleans, Dec. 16, 1884–May 31, 1885; reopened in Nov., 1885, for a short time; organized by the Cotton Planters' Association. There were 29 large buildings and 23,000 exhibitors. In the spring of 1891 a very successful international exhibition was opened on the island of Jamaica by Prince George of England. The great exhibition opened in Chicago May 1st, 1893, to commemorate the discovery of America, was under the dual control of a commission of 113 members appointed by Congress and a corporation of 45 citizens established under the laws of the state of Illinois, consisting of 45 prominent citizens of Chicago. By act of Congress, the sum of \$1,500,000 was provided for the erection of special buildings for government exhibits. The city set apart 560 acres in Jackson Park and 80 acres in Midway Plaisance. The President of the United States invited by proclamation of Dec. 24, 1890, the participation of foreign nations; and on Oct. 21, 1892, the Vice-President, representing the President, dedicated the Exposition, the oration being pronounced by Mr. C. M. Depew of New York. The formal opening was on May 1, 1893, having been preceded by a great naval review in New York Harbor (April 27), in which, besides the United States, war-vessels from England, France, Germany, Russia, Spain, Italy, Holland, Brazil, and Argentina participated. The buildings at the Columbian Exposition surpassed in size and beauty those seen at any previous World's Fair. The cost of this Exposition is estimated at \$25,000,000. See WORLD'S COLUMBIAN EXPOSITION.

EX'MOOR FOREST, a moory, mostly uncultivated waste, consisting of dark ranges of hills and lonely valleys, 14 sq.m. in area, in the w. of Somersetshire and n.e. of Devonshire. It is bordered by deep wooded glens.

EX MOUTH, a t. in the e. of Devonshire, on the left bank of the mouth of the Exe, 10 m. s.e. of Exeter. It stands at the base and on the slope and top of a hill rising from the sandy estuary of the Exe. It is noted for its mild climate. From about 1700, it was the chief watering-place on the Devon coast, till the rise of Torquay. There are promenades, baths, terraces and pleasure-grounds along the shore. The Woodbury Hills on the e., 800 ft. high, protect it from the e. winds. Here Swend the Dane landed in 1003. It was taken by the royalists in 1646. Pop. '81, 6245; '91, 8097.

EXMOUTH, EDWARD PELLEW, Viscount, a famous naval commander, was b. at Dover, April 19, 1757. He entered the navy when 13 years of age, and first attracted notice by his gallant conduct in the battle on lake Champlain, Oct. 11, 1776. In 1782, he attained the rank of post-capt. In 1793, having been appointed to the command of the *Nymph*, a frigate of 36 guns, he encountered, and, after a hard-fought battle, captured *La Cleopatre*, a French frigate, which carried the same number of guns. For this victory, he was knighted. In 1799, he received the command of the *Impétueux*, 78 guns, and was sent to the French coast, where many of his most brilliant actions took place. In 1804, sir E. Pellew was advanced to the rank of rear-admiral of the Red; in 1808, to that of vice-admiral of the Blue; and in 1814, he was raised to the peerage, with the title of baron E. of Canonteign, Devonshire, with a pension of £2,000 a year. In 1816, he was sent to Algiers, to enforce the terms of a treaty regarding the abolition of Christian slavery, which the dey of Algiers had violated. With a combined fleet of 25 English and Dutch vessels, he bombarded the city for seven hours, and inflicted such immense damage, destroying all the Algerine fleet and many of the public buildings,

that the dey consented to every demand. E., who had been wounded in the leg and cheek in this action, received on his return to England the thanks of both houses of parliament, and was promoted to the rank of viscount, 10th Dec., 1816. In 1821, he retired from public service, loaded with honors. He died 23d Jan., 1833.

EXOCETUS. See FLYING-FISH.

EXODUS ("the departure"), the name given to the second book of the Pentateuch. It may be regarded as composed of two parts—the first historical, and the second legislative. The historical extends to the end of the 18th chapter. It embraces a narrative of the various preparations, natural and supernatural, made under the providence of God for the deliverance of the Israelites from their bondage in Egypt, and also describes the accomplishment of their deliverance, and the journeyings of the people in the wilderness as far as Mt. Sinai. The legislative is devoted to a minute and elaborate account of the institution of the theocracy. The book presents us with three aspects of Hebrew history. We have, first, a picture of a people enslaved; second, of a people redeemed from bondage; and third, of a people sanctified and set apart, to the service of God. The period embraced by the history of the book is usually reckoned at 142 or 145 years, which number is obtained as follows: From the death of Joseph to the birth of Moses, 60 or 63 years; from the birth of Moses to the departure from Egypt, 80 years; and from the departure out of Egypt to the erection of the tabernacle, 1 year. It cannot be denied, however, without wildly violating all the ordinary laws of the increase of population, that this is much too short a period to account for the existence of such a number of Hebrews as left Egypt—viz., 600,000, exclusive of women and children—i.e., in all, at least, 2,500,000. Those who went down into Egypt with Jacob were "threescore and ten souls," and in 215 years, these, though prohibited from intermarrying with the Egyptians, had amounted to between two and three millions. The writer of E., indeed, says (chapter xii., verse 40) that "the sojourning of the children of Israel, who dwelt in Egypt, was 430 years," adding that they left the land "even the self-same day" on which they had entered it. This statement, however, does not seem to harmonize with the author's previous narrative, and is certainly inconsistent with the language of the apostle Paul, who says (Gal. iii. 17) that the law was given 430 years after the covenant with Abraham, which took place about 215 years before Jacob and his sons went down into Egypt, so that, according to this view, the Israelites could only have been in Egypt 215 years. This is the number commonly accepted; but it is not wonderful that some writers should affirm that "it would be more satisfactory if we could allow 430 years for the increase of the nation in Egypt rather than any shorter period." A still longer period would undoubtedly afford additional satisfaction; and Bunsen, in his *Ägypten's stelle in der Weltgeschichte*, endeavors to show that the Israelites were in Egypt for *fourteen* centuries instead of two, and that the number 215 only indicates the period of oppression, the time when they were "evilily entreated." This conclusion is, of course, arrived at by the application of principles of criticism not generally recognized in the schools of British theology; but there seems no avoiding the conclusion, that the usual chronology is hopelessly wrong.

May it not be that the interval which elapsed between the death of "Joseph and all his brethren, and all that generation" (E. i. 6), and the period when there arose up a new king over Egypt which knew not Joseph (E. i. 8), was much longer than we suppose? The passage itself in E. seems to favor this idea; for the intervening verse (E. i. 7) speaks of the children of Israel "increasing and multiplying, and waxing exceeding mighty, and filling the land," without any reference at all to the time occupied in this process; and such words are certainly more applicable to a series of centuries than of years, while centuries, besides, would harmonize better than years with the statement that the Egyptian king knew not (i.e., had forgotten all about) Joseph. The only grave objection to this otherwise extremely probable hypothesis, is its incompatibility with the statement of St. Paul; an objection, however, which Luther would not have found insurmountable, for in an exactly similar case he said of the inspired Stephen that "he was no historian, and did not trouble himself about particulars."—*Zu Apostelgesch.* vii. Bd. 1, 1160.

In explanation of the chronological difficulty, the confusion resulting from the use of *letters* as numerals in Hebrew MSS. has been urged; and this is notoriously a fertile source of error and contradiction, which rationalistic critics have not sufficiently kept in mind. To adduce such a reason, however, would be unavailing in the present case; for if it could be proved that the period stated in E. may have been abbreviated through the negligence of some careless transcriber, or otherwise, and thus an approximation be made to the *fourteen* centuries of Bunsen, this would only place the writer of the Pentateuch in more visible antagonism with St. Paul himself. The date of the exodus is fixed by Usher at 1491 B.C.; by the Septuagint, at 1614 B.C.; by Hales at 1648 B.C.; by Wilkinson, about 1495 B.C., in the reign of Thothmes III.; and by Bunsen, as late as 1320 or 1314 B.C., in the reign of Menephthah, in the latter of which years Manetho gives what appears to be the Egyptian version of the event. The genuineness and authenticity of the book of E. have been sharply criticised in modern times; but in fact, as early as the time of Josephus (*Ant.*, ii. 16), there were Jews who looked upon the miracle of the crossing of the Red sea, etc., as fabulous. Among the theologians

who have questioned the integrity of E., are Von Lengerke, Stähelin, De Wette, Knobel, and Colenso, who find traces of an older and a later author, the former of whom they call Elohist, and the latter Jehovistic. Their objections have been replied to by Hengstenberg, Hävernick, etc., who endeavor to show that the distinction is artificial, and the attempt to follow it out in detail a failure. See PENTATEUCH.

EXOGENY. This term signifies marriage outside the limits of one's family, clan, or nation, and it is opposed to endogamy or intermarriage between those who are closely related. Looked at from a physiological standpoint, it is conceded that exogamy is productive of the best results to the human family, as continued intermarriage weakens the race physically and mentally. The origin of exogamy is traced to the custom of infanticide among the females in early barbaric times, thus creating a scarcity of wives, which led the young men of the tribes to capture the women of neighboring tribes by force. The old Roman legend of the *Rape of the Sabines* is an illustration of this fact. The circumstances most opposed to exogamy are the distinctions of caste (q.v.), totem (q.v.) religion, and policy. See MARRIAGE.

EXOGENOUS PLANTS, or EXOGENS (Gr. *exo*, outwards; *gennao*, to produce), are those in which the woody substance of stem increases by bundles of vascular tissue added externally. The exogenous stem contains a central *pith* (q.v.), from which *medullary rays* proceed to the bark (q.v.), and the bark is very distinct from the fibro-vascular or woody part which it surrounds. The exogenous is thus very different in structure and manner of growth from the endogenous or the acrogenous stem. Amidst the cellular substance of the young stem, when it has developed itself from the seed, woody cords are seen connecting the cotyledons, and afterwards the leaves, when these appear, with the root, in the central axis of which they join. A section of the stem exhibits the cellular substance traversed by vascular bundles (woody fiber), which in the section are more or less wedge-shaped, radiating from the center, but yet not prolonged into the center itself, which, even to the greatest age of the stem, remains occupied by the cellular pith. Additional bundles are interposed, as growth proceeds, diminishing the proportion of cellular substance in the stem, yet without these bundles ever becoming so compacted together as to cut off the communication between the cellular center of the stem and its bark, which is maintained by means of the medullary rays, often, indeed, imperceptible to the naked eye, but always present even in the hardest and most close-grained wood. The woody layers which are formed in successive years, as new leaves and branches are developed, are formed amidst the *cambium* (q.v.), into which the woody fibers of the new leaves descend, between the bark and the former wood. Thus the concentric circles are formed, usually one for each year's growth, distinguishable even in the most matured timber, and by which the age of trees is very commonly computed. The beginning of each new layer is generally marked by a greater abundance of *porous vessels*, the openings of which are conspicuous in the transverse section. In pines, the line of separation between the layers is marked by greater density of texture, and often by deeper color. The age of trees cannot, however, be calculated with perfect certainty from the concentric circles of the stem, as any circumstance which temporarily arrests the growth in any summer, may produce an effect similar to that ordinarily produced by the change of seasons; whilst in the trees of tropical countries, at least where the wet and dry seasons are not very marked, concentric circles are often not to be discovered.

The structure of the branch of an exogenous tree perfectly corresponds with that of the stem. The vascular bundles of the stem or branch form a loop where a leaf begins, and those of the leaf and its axillary bud spring from the loop. The roots of exogenous plants have not a central pith like the stem, but in a few trees, as the horse-chestnut, the pith is prolonged to some extent into the root.

Anomalies are not unfrequently to be met with in the structure of exogenous stems, and particularly among the twining woody plants of tropical countries. There are also very many herbaceous plants, in which, although the structure agrees with that of an exogenous tree in its first year, no further development is ever attained; whilst in many, even this is very imperfectly reached; but yet these are on other accounts unhesitatingly classed with exogenous plants. The exogenous stem and dicotyledonous seed are so constantly found together, that the designation exogenous plants is often applied to that great division of the vegetable kingdom, which is also called dicotyledonous. See BOTANY.

EXORCISM (from *exorkizo*, to conjure), i.e., conjuration in the name of the gods, the term used by the fathers of the church to denote the act of conjuring evil spirits, in the name of God or Christ, to depart out of the person possessed. The first Christians adjured evil spirits in the name of Jesus Christ, who had conquered the devil; but as the opinion was at the same time entertained, that all idolaters belonged to the kingdom of Satan—who suffered himself to be worshiped under the form of idols—it was customary to exorcise heathens previous to their receiving Christian baptism. After Augustine's theory of original sin had found acceptance in the 5th c., and all infants were regarded as belonging to Satan's kingdom, E. became general at the baptism even of Christian children. Following the practice of the Roman Catholic church, Luther retained E., but it was laid aside by the Reformed church. Although abandoned by

illustrious and orthodox Protestant theologians, such as Chemnitz and Gerhard, or deemed unessential, and in modern times done away with by the "Protestant" church, the practice has been recently revived by the Old Lutheran or High-church party.

In the Catholic church, the function of E. belongs peculiarly to one of the so-called "minor orders." See **ORDERS, HOLY**. Our Lord having not only himself in person (Matt. ix. 32, Mark i. 25, Luke iv. 35, viii. 29) cast out devils, but having also given the same power to his disciples, it is believed to be permanent in the church. Of its exercise in the early church, both in relation to "energumens," or persons possessed, and in the administration of baptism, there are numerous examples. Tertullian and Origen speak of it as of ordinary occurrence, and the council of Carthage, in 255, alludes to its use in baptism. The rite of E. is used by the modern church in three different cases: in the case of actual or supposed demoniacal possession, in the administration of baptism, and in the blessing of the chrism or holy oil, and of holy water. Its use in cases of possession is now extremely rare, and in many diseases is prohibited, unless with the special permission of the bishop. In baptism it precedes the ceremony of applying the water and the baptismal form. It is used equally in infant and in adult baptism, and Catholic writers appeal to the earliest examples of the administration of the sacrament as evidence of the use of E. in both alike. The rite of baptismal E. in the Roman Catholic church follows closely the scriptural model in Mark viii. 33. The exorcisms in the blessing of the oil and water resemble very closely the baptismal form, but are more diffuse.

EXOSMOSE. See **ENDOSMOSE**.

EXOSTEMMA, a genus of American trees and shrubs of the natural order *cinchonaceæ*, nearly allied to *cinchona*. Several species yield febrifugal barks, which, however, do not contain the cinchona alkaloids. The most valued of these barks are Caribbee bark (q.v.) and Saint Lucia bark, the latter of which is the produce of *E. floribunda*, a native of the more mountainous parts of the West Indies.

EXOSTOSIS (Gr. *ex*, out of, and *osteon*, bone), a bony tumor growing from some of the osseous structures of the body. See **TUMORS**.

EXOTERIC. See **ESOTERIC**.

EXOTIC PLANTS, or **EXOTICS** (Gr. coming from abroad), cultivated plants originally derived from foreign countries. The term is most frequently applied to those of which the native country differs so much in soil or climate from that into which they have been conveyed, that their cultivation is attended with difficulty, requiring artificial heat or other means different from those requisite in the case of indigenous plants. The cultivation of many such exotics is carried on with great success in our greenhouses and hot-houses; but there are a few which, notwithstanding all the care of the gardener, can almost never be made to flower, and others which, although they flower, seldom produce ripe fruits and seeds. Nor are difficulties of this kind experienced only in the cultivation of those which belong to warmer climates than our own, but sometimes even with the natives of colder regions; thus, the delicious fruit of the *rubus arcticus*, abundant in the most northern parts of Europe, is scarcely ever to be seen in the gardens of Britain, although the plant grows with sufficient luxuriance.

EXPANSION. See **HEAT**.

EXPATRIATION, a voluntary change of residence and allegiance from one's native land to another country and government. Despotie governments have assumed the right to forbid such a change on the part of their citizens, but the United States recognizes the right of the individual citizen, at his own pleasure, to leave the country of his birth and make his home in a foreign land. Naturalization, however, is necessary to the complete transfer of allegiance. The United States defends the rights and liberties of naturalized, precisely as it does those of native citizens. A naturalized citizen of this country, visiting his native land, is protected by the American flag as though he had been born on American soil. Of course, this right of expatriation cannot be made a cover for a previous breach of trust, or the commission of any crime, in the place of one's birth; but the assumption that the law of his native land requiring him at a certain time of his life to do military duty, nullifies for the time being a man's right of expatriation, is not allowed by the United States. Thousands of young men leave the old world for the avowed purpose of avoiding military conscription, and the United States welcomes them to citizenship, with all its rights and obligations.

EXPECTATION (Lat. *expectatio*, a waiting, or looking out), i.e., the treatment of disease without active remedies, by simply observing its progress and averting its consequences through physiological means; as, for instance, when a fracture (q.v.) is treated by keeping the ends of the broken bone in their proper place, until the natural processes of repair are completed. E. is in this and other cases obviously a quite different thing from inaction, or the systematic doing of nothing, with which it has been sometimes confounded.

EXPECTATION OF LIFE. See **PROBABILITY**.

EXPECTATION WEEK is the name given to the period elapsing between Ascension day and Whitsunday, because during this time the apostles continued praying in earnest expectation of the Comforter.

EXPECTORANTS (Lat. *ex*, out of, and *pectus*, the breast), medicines given to carry off the secretions of the air-tubes. See BRONCHI, BRONCHITIS. The principal E. are antimony, squill, ipecacuanha, senega, balsam of tolu, lobelia, gum ammoniac, asa-fœtida, galbanum, etc.

EXPECTORATION (see EXPECTORANTS), the mucus or other secretion discharged from the air-passages. The examination of E. is of the utmost value in the diagnosis of diseases of the chest, as will be seen in their separate description. See CHEST, BRONCHITIS, PNEUMONIA, CONSUMPTION, etc.

EX PEDE HERCULEM. (Latin proverb.) "You can judge of Hercules from his foot" meaning that the whole can be tested by a part. The saying is assigned to Pythagoras, and is paralleled by another similar phrase, *ex ungue leonem*, "You can judge of a lion by his claw."

EXPEDITATION is the cutting off of the claws or the ball of the forefeet of a dog, to prevent his running after deer.

EXPENSE MAGAZINE. A military term used of the immediate store of ammunition for the batteries of a siege, and formed under the parapet.

EXPENSES or COSTS of a LAWSUIT. The arrangements adopted in England with reference to charges exigible from the parties to lawsuits are stated under COSTS. In the United States of America, the statutes generally provide that the successful party shall be reimbursed for disbursements made for certain necessary objects, as, e.g., clerk's fees, etc. There are allowed besides these disbursements certain sums of money called costs, strictly speaking. The law does not recognize, however, any claim of the successful party against the other for money expended for attorney's and counsel's fees. Doubtless it was originally intended that the statutory costs should help towards this end, but as a matter of fact costs are generally regarded as a sort of honorarium to which the successful attorney is entitled.

EXPERIENCE MEETING. A name applied to religious gatherings at which one or more of those present set forth their spiritual history and experiences. In the Methodist church they are called class-meetings, and among some other denominations covenant or conference meetings. The ordinary prayer-meeting of a church sometimes takes this form. Much criticism has been made of this kind of public confession, as tending to foster self-pride and to lead its participants into saying more than is strictly true, but those who defend the custom quote in its favor such Bible verses as Mal. iii. 16; Col. iii. 16, and claim that it has a most edifying and strengthening effect.

EXPERIENTIA DOCET. (Latin.) Experience teaches; i.e., one must learn by experience.

EXPERIENTIALISM is the doctrine that experience is the foundation of all knowledge, and that all primary beliefs—personal identity, uniformity of nature, etc.—are only generalizations from one's own experience and that of others. Thus Experientialism is a somewhat less extreme form of DETERMINISM (q.v.), and is opposed to Intuitionism, which claims that primary beliefs are instinctive, naturally implanted, and spontaneously developed.

EXPERIMENT and observation are the means by which we extend and confirm our knowledge of nature. An E. is properly a proceeding by which the inquirer interferes with the usual course of a phenomenon, and makes the powers of nature act under conditions that, without his interference, would never, perhaps, have presented themselves all together. The introduction of E. distinguishes the modern method of investigating nature from that of ancient times and of the middle ages. It is by this means that physics and chemistry have made such rapid strides within the last two centuries. Through E., the investigator becomes master of the phenomena he is considering; for he can contrive to set aside the unessential circumstances that so often conceal the real relations and conditions of things, and make these come out into the light. Experiments exhibited during a lecture on any branch of science are made, not with a view to the discovery of truth, but to aid in the exposition of truths already discovered; they are sometimes called demonstrative experiments.

EXPERIMENTALISM. See EXPERIENTIALISM.

EXPERIMENT MILLS is a small village in Monroe Co., Pennsylvania, about two miles from Delaware Water Gap. It is becoming something of a summer resort.

EXPERIMENTUM CRUCIS. A crucial test. The name is employed, according to Bacon, because, like a cross (*crux*), it shows men which of two ways they are to follow.

EXPERT (Lat. *expertus*, from *ex* and *peritus*, specially skilled), a man of special practical experience or education in regard to a particular subject—a word commonly applied (after the French) to medical or scientific witnesses in a court of justice, when selected on account of special qualifications, as in the case of an analysis of the con-

tents of the stomach in suspected poisoning. The term is similarly applied to a person professionally skilled in hand-writing, for detection of forgery of deeds and signatures.

EXPIATION OR **ATONEMENT**, DAY OF, among the Jews, is the 10th day of the month Tisri (corresponding to a part of our Sept. and Oct.), observed annually as a day of humiliation and atonement for national sin: the only day of national humiliation which Moses prescribed. The commandment to observe it was three times solemnly given, and the religious ceremonies peculiar to it were definitely ordained. All the people were required to refrain from work as strictly as on the Sabbath, and to afflict their souls in remembrance of their sins. In this humiliation fasting was probably designed to be included, and has been strictly practiced. The chief significance of the observance, as also its heaviest burden, centered in the high-priest as the representative of the nation before God. 1. The seven previous days were spent by him in nearly total separation from all other persons, and in careful preparation for his special duties. 2. "During the whole of the seven days, as well as on the day of atonement" (according to the statements of the rabbins) "the high-priest had to perform the ordinary sacerdotal duties of the daily service himself." 3. It was the only day of the year in which even he was allowed to enter the most holy place. 4. He was clothed in the linen priestly vestments instead of the splendid robes which at other times distinguished him. 4. He offered sacrifice first for himself and his house, sprinkling the blood and burning incense before the mercy-seat. 5. He took two goats for the sin-offering in behalf of the people, presenting both before the tabernacle, and having cast lots to determine which one should die, sacrificed it on the altar and carried its blood within the veil; then having confessed over the head of the living goat all the sins of the people, he sent it away under the charge of a trusted man to be set free in an uninhabited part of the wilderness. By this double offering as parts of one sacrifice the two great facts of redemption were represented: 1st, that an atonement for sin was made to God; and 2d, that the burden of sin was removed from man. In modern times the Jews continue to observe the day, beginning the ceremonies with what can be regarded at best, as only a mournful parody on the offering of the scape-goat, fasting strictly through the day, and closing the service by reading the Scripture command for sacrifices which they can no longer bring.

EXPLOITS, RIVER OF, one of the largest rivers in Newfoundland, rising in the s.w. part of the island and running n.e. to the bay of Exploits, into which it falls about 49° n. and 52° w. Steamers go up 12 m., and small boats can pass to within 50 m. of the s.w. coast. The valley is fertile and abounds in game, being sparsely settled as yet, and the river is bountifully supplied with fish.

EXPLOSIVES. There is a question as to the influence, direct or indirect, upon modern civilization of the introduction of explosive agents for the purpose of war. Some eminent authors have gone so far as to consider the invention of gunpowder as next in importance, in its ultimate effects, to those of printing and the application of steam power. However this may be, it is well to remember that explosive substances are now of immense utility in the arts of peace; indeed, it is not too much to say that without their aid many of the great engineering enterprises of the present day would either be impossible, or else have to be carried out at a vast additional expenditure of time and labor. The germ of all the knowledge which we possess of explosive reaction undoubtedly lay in the probably accidental discovery, many ages ago, of the deflagrating properties of the natural substance niter or saltpeter, KNO_3 , when in contact with incandescent charcoal. By distilling niter with oil of vitriol, the alchemists obtained a corrosive fluid which they called *aqua fortis*, now known as nitric acid, HNO_3 , which parts with its oxygen even more rapidly than saltpeter; so that if the strongest nitric acid be poured upon finely powdered charcoal, the latter takes fire at the ordinary temperature. Somewhat less than half a century back, it was discovered by some French chemists that upon treating various organic substances, such as starch, the sugars, cotton fabrics, and even paper, with concentrated nitric acid under proper precautions, the chemical constitution of the substances underwent a great change, and they became endowed with violently explosive properties, while remaining for the most part unaltered in external characteristics. To this discovery we owe a distinct class of explosive compounds, the most powerful for practical purposes as yet known.

Examining into those principles of constitution and action which are more or less common to all explosive substances, we may define, for our purpose, the term "explosive" as the sudden or extremely rapid conversion of a solid or liquid body of small bulk into gas or vapor, occupying very many times the volume of the original substance, and, in addition, highly expanded by the heat generated during the transformation. This sudden or very rapid expansion of volume is attended by an exhibition of force, more or less violent according to the constitution of the original substance and the circumstances of explosion. Any substance capable of undergoing such a change upon the application of heat, or other disturbing cause, is called "explosive." The most explosive substances that are practically the most important essentially contain carbon, oxygen, and nitrogen, the last always existing in a state of feeble combination with the whole or part of the oxygen, and thus creating that condition of unstable chemical equilibrium which is necessary. When explosion takes place, the nitrogen parts with

its oxygen to the carbon, for which it has a greater affinity, forming carbonic acid (CO_2) and carbonic oxide (CO) gases, the combination being accompanied with great generation of heat, and the nitrogen is set free. In most explosives there is also hydrogen accompanying the carbon, and by its combustion producing an extremely high temperature; it combines with part of the oxygen to form water in the form of greatly expanded vapor. Other subordinate elements are often present; in gunpowder, for instance, the potassium binds the nitrogen and oxygen loosely together in the state of saltpeter, and there is sulphur, a second combustible, whose oxidation evolves greater heat than that of carbon. When chlorate of potash is present, the chlorine plays the part of nitrogen, and is set free in the gaseous state. Two very unstable and practically useless explosive substances, the so-called chloride and iodide of nitrogen, contain neither carbon nor oxygen; but their great violence is equally caused by the feeble affinities of nitrogen for other elements, large volumes of gaseous matter being suddenly disengaged from a very small quantity of a liquid and solid body respectively.

Explosives may be conveniently divided into two distinct classes—(1) explosive mixtures, and (2) explosive compounds. The first class consists of those explosive substances which are merely intimate mechanical mixtures of certain ingredients, and which can be again separated more or less completely by mechanical means, not involving chemical action. These ingredients do not, as a rule, possess explosive properties in their separate condition. There are, however, explosives which might almost be classed in both categories; for example, *picric powder* is composed of ammonium picrate and saltpeter, the former of which contains an explosive molecule, but is mixed with the latter to supply additional oxygen, and thus increase the force. If a substance that will burn freely in air, combining gradually with the oxygen of the atmosphere, be ignited in pure oxygen gas, the combustion will be much more rapid, and the amount of heat generated greater, at the ordinary atmospheric pressure. If it be possible to burn the substance in a very condensed atmosphere of oxygen, we can readily imagine the combustion as very greatly accelerated, and therefore increased in violence; this is what is ordinarily effected by an explosive "mixture." A combustible body and a supporter of combustion are brought into extremely close contact with one another by means of intimate mechanical mixture; also, the supporter of combustion, or oxidizing agent, is present in very concentrated form, constituting what may be termed a magazine of condensed oxygen, solid or liquid. In the case of the explosion of a definite chemical compound, the change may be considered as the resolution of a complex body into simpler forms. This is not, however, always the case when a mechanical mixture is concerned; gunpowder, for example, may be said to contain two elementary substances, carbon and sulphur, not in chemical union.

The chief explosive mixtures may be subdivided into "nitrate mixtures" and "chlorate mixtures." In the nitrates, the oxygen is held in combination with sufficient force to need a powerful disturbing cause to separate it, so that mixtures made from nitrates do not explode very rapidly, and their action is comparatively gradual; they are not sensitive to friction or percussion, and hence are to a great extent safe. Any of the nitrates will form explosive mixtures with combustible substances, but nitrate of potash, KNO_3 , is the only one practically employed. The nitrate of soda, called "cubical" or Chili saltpeter, has been used, but absorbs moisture from the air so readily as to give very inferior results. Gunpowder may be taken as the representative of the nitrate explosive mixtures. Picric powder, above referred to, has been proposed by Abel for use as a bursting charge for shells, as being more powerful than a corresponding charge of gunpowder, equally safe as regards friction or percussion, and less hygroscopic; it consists of two parts ammonium picrate, and three parts saltpeter, incorporated, pressed, and finished very much as ordinary gunpowder.

The chlorates part with their oxygen far more readily than the nitrates, the strong affinities of chlorine for the metals coming into play, and consequently chlorate mixtures are very sensitive to friction and percussion, and explode with great violence; chlorate of potash, KClO_3 , is the only one used. Very many chlorate mixtures have been made, some of which are employed in fireworks. "White gunpowder" is a mixture of two parts chlorate of potash, one of yellow prussiate of potash, and one of sugar; it is exploded very easily by friction or percussion. The most important chlorate mixtures are those used for igniting other explosives, such as the composition for friction tubes for firing cannon, percussion-cap composition, and percussion fuses for bursting shells on impact; it is sometimes mixed with sulphur, as a combustible, and sometimes with black sulphide of antimony, which gives a longer flame.

In an explosive "compound," the elements are all in chemical combination, presenting a definite explosive "molecule," which contains, so to speak, both the combustible and the supporter of combustion, in the closest possible union; we can therefore understand its action being much more sudden and violent than that of the most intimate mechanical mixture. The chief explosive compounds are formed from some organic substance containing carbon, hydrogen, and oxygen, by introducing into it, through the action of concentrated nitric acid, a certain portion of nitric peroxide NO_2 , in substitution for an equivalent amount of hydrogen. A new compound, differing outwardly very little, if at all, from the original substance, is thus formed, but in a very unstable state of chemical equilibrium, because of the feeble union of the nitrogen

and oxygen in the NO_2 molecule. A slight disturbing cause brings into play the stronger affinity of the carbon and hydrogen for the large store of oxygen contained in the new compound. Gun-cotton and nitro-glycerine are the leading members of this group, being produced in a precisely similar manner, by the substitution of three molecules of NO_2 for three atoms of hydrogen (H). As those explosives will be elsewhere described in detail, we give the formation, as a representative member of the group, of nitro-phenol, or picric acid, by treating phenol, or carboic acid, with a mixture of nitric and sulphuric acids, the latter being required to absorb the water and preserve the full strength of the nitric acid:

The formula of the product may be empirically written $\text{C}_6\text{H}_3\text{N}_3\text{O}_7$; it is, like gun-cotton and nitro-glycerine, a *tri-nitro* substitution product. Only the picrates, or salts of picric acid formed with potassium or ammonium, are used in practice, as possessing more force than the uncombined acid. From starch may be obtained, in a strictly analogous manner, an explosive called *xyloidine*, which is a *bi-nitro* product, two molecules of nitric peroxide being substituted for two atoms of hydrogen. In the case of *nitro-mannite*, an explosive made from mannite, one of the sugars, as many as six molecules of the NO_2 are inserted. The number of nitro-substitution products is very great, many of them being more or less violently explosive. The fulminates are among the most violent of all explosive compounds, their chemical sensibility being very small. Sudden in action, their effect is great locally; thus they are well adapted to the purpose, for which alone they are practically used, of igniting or upsetting the equilibrium of other explosives. Fulminate of mercury is produced by adding alcohol ($\text{C}_2\text{H}_6\text{O}$), under great precautions, to a solution of mercury in nitric acid; a gray crystalline precipitate is obtained, very heavy (sp. gr. 4.4), and so sensitive to friction or percussion that it is kept in the wet state. The results of analysis show one atom of mercury, and two each of carbon, nitrogen, and oxygen; so that the formula may be empirically written $\text{HgC}_2\text{N}_2\text{O}_2$, or perhaps more correctly $\text{HgO.C}_2\text{N}_2\text{O}$; the chemical factor $\text{C}_2\text{N}_2\text{O}$ is called *fulminic acid*, but has never been produced separately. Opinions differ as to the precise "rational" formulæ of the fulminates, some chemists considering their process of formation to be similar to that of the nitro-substitution products. It will be observed that two atoms of nitrogen take the place of hydrogen, being the ratio of combining proportions of those elements. The products of combustion are carbonic oxide, nitrogen, and metallic mercury, and the violence of action is due to the sudden evolution of a volume of gas and vapor very large in comparison with that of the substance, its density being so great. This fulminate enters into the composition used for percussion caps and electric fuses; its practical value has of late years been immensely increased by the discovery of its power, even in very small quantities, to produce the almost instantaneous decomposition of several explosive substances. Fulminate of silver is prepared in a similar manner, but, being far more sensitive, is of little practical value; it is employed, in very minute quantities, in making such toys as detonating crackers.

It may be generally concluded that the amount of force exerted by an explosive substance depends upon (1) the *volume of gas or vapor* produced by the transformation, compared with that of the original substance; and (2) the *temperature of explosion*, which determines the extent to which the gases are expanded, or their tension increased; or, in other words, the explosive force is directly proportional to the heat of combustion, and the volume of gas and vapor calculated at 0°C . and 7.60 mm. pressure, and *inversely* proportional to the specific heat of the mixed products. It has been supposed by Berthelot and others that the volume of gas produced may possibly be still further increased by the partial or total "dissociation" of the compound gases, at the high temperatures concerned; for example, that the carbonic acid (CO_2) may be decomposed into carbonic oxide (CO) and oxygen, or the aqueous vapor into oxygen and hydrogen. However, Nobel and Abel demonstrate that, in the former instance, the loss of temperature, consequent upon the absorption of heat by the decomposition, would more than compensate for the increase of volume by dissociation. It must also be remembered that, if the temperature be extremely high, so also is the pressure under which dissociation must take place. We may therefore consider that it has no sensible influence upon the explosive force.

It is most important to distinguish between explosive force and explosive effect, the latter in great measure depending upon the rapidity with which the metamorphosis takes place, while the same amount of force may be exerted suddenly or gradually. We may, therefore, consider that the explosive effect varies *directly* as the volume of gas produced and the temperature of explosion, and *inversely* as the time required for the transformation. But the time, and, to a certain extent, the products and temperature, will vary with (a) the physical state of the explosive substance; (b) the external conditions under which it is fired; (c) the mode of firing or exploding.

The physical or mechanical state of the explosive substance has a most important bearing upon the effect obtained from it. To prove this, it is only necessary to point to the very different results given by gunpowders made with the same proportions of the three ingredients, but varying in density, and in shape and size of grains or pieces.

Gun-cotton is even more affected by variations in mechanical condition. In the form of loose wool, it burns so rapidly that gunpowder in contact with it is not inflamed; plaited or twisted tightly, its rate of combustion in air is greatly modified. This is due to the fact that the inflammable carbonic oxide, which is evolved by the decomposition from the want of sufficient stored-up oxygen to oxidize completely all the carbon of the gun-cotton, cannot penetrate between the fibers and accelerate the combustion, but burns with a bright flame away from the surface of the twisted cotton: when the yarn is yet more compressed by any means, the temperature is not kept up to the height necessary for the combustion of the carbonic oxide, so that it escapes unconsumed, abstracting heat, and yet more retarding the rate of burning. For the same reason, pulped and compressed gun-cotton burns comparatively slowly in air, even when dry; in the wet state, it merely smolders away, as the portion in contact with the fire successively becomes dried. Yet this same wet compressed gun-cotton can be so used as to constitute one of the most powerful explosives known.

It is well known that gunpowder behaves differently when in the open air and under strong confinement; not only the rate of burning, but even, to a certain extent, the products of combustion are altered. We have discussed the effect of tightly plaiting or compressing gun-cotton; but when confined in a strong envelope, the whole of the inflamed gas, being unable to escape outwards, is forced into the interstices under immense pressure, and the decomposition is greatly accelerated. The amount of confinement or restraint needed by any explosive depends, however, upon the nature of the substance and the mode of exploding it, becoming very much less as the transformation is more rapid, until it may be said to reach the vanishing-point. For example, the very violent explosive chloride of nitrogen is usually surrounded, when exploded, with a thin film of water. Abel states that if this film, not exceeding $\frac{1}{1000}$ in thickness, be removed, the explosive effect is much lessened. Nitro-glycerine, again, when detonated by a fulminate, is sufficiently confined by the surrounding atmosphere. By the same means, gun-cotton may be exploded unconfined, if compressed, the mechanical cohesion affording sufficient restraint. In the case of wet compressed gun-cotton, which can be detonated with even fuller effect than dry, the mechanical resistance is greater, the air-spaces being filled with incompressible fluid.

The manner in which the explosion is brought about has a most important bearing upon the effect produced. This may be done by the direct application of an ignited or heated body, by the use of an electric current to heat a fine platinum wire, or by means of percussion, concussion, or friction, converting mechanical energy into heat. A small quantity of a subsidiary explosive, such as a composition sensitive to friction or percussion, is often employed, for the sake of convenience, to ignite the main charge, the combustion spreading through the mass with more or less rapidity, according to the nature of the substance. See EXPLOSIVES OF HIGH POWER.

EXPLOSIVES OF HIGH POWER. For over four hundred years the science of explosives remained in *statu quo*. In 1328 Berthold Schwartz, of Freiberg, is credited with the invention of gunpowder, although many records are in existence which indicate that prior to that date the Arabs knew the use of an explosive mixture, which they called *Medfoa*. This consisted of 10 drachms of saltpetre, 2 drachms of charcoal, and $\frac{1}{2}$ drachms of sulphur; and it is noteworthy that these proportions closely resemble those of the present formula of English gunpowder—namely, 74.07 saltpetre, 14.82 charcoal, and 11.11 sulphur. The first advance leading to the introduction of modern high explosives was made in 1832, by the French chemist Barconnet, of Nancy, who discovered that “when starch fibres and analogous substances are acted upon by concentrated nitric acid, they are changed into highly combustible materials.” In 1838 Pelouze continued these researches, and he ascertained that this new inflammable material, which he called xyloidine, took fire at 180° C., when submitted to strong pressure, such as a rapid blow. He also found that cotton, paper, and, indeed, all vegetable matters could be employed in the preparation of similar substances. All these researches, however, were without any practical value until Schönbein, of Bale, in 1845, devised methods for the manufacture of a new explosive on a commercial scale, by treating gun-cotton with a mixture of nitric and sulphuric acids. In 1847 Sobrero, an Italian chemist, discovered in Pelouze's laboratory, in Paris, the explosive properties of nitro-glycerine, but the discovery was without practical application until 1860, when the Swedish engineer, Alfred Nobel, devised methods for the manufacture of the substance on a large scale, and also succeeded in exploding it with certainty when under confinement. He patented it under the name of Nobel's Blasting Oil, and subsequently he found a ready means of absorbing the oil in porous substances, thereby producing the now famous dynamite, or giant powder. From this time the progress of explosives has been remarkably rapid; the ablest chemists and the best engineers have found in the study of explosives a fruitful field. Their rapidly extending use for the removal of masses of rock has directed attention to their nature and mode of action, and has also led to numerous attempts to increase their effectiveness, to modify their action to suit their different uses, and to reduce their danger. Every miner knows the importance of having as much as possible of the charge at the bottom of the bore-hole; it is there that the maximum amount of work is exerted; and as the explosives contain the stored-up energy in a smaller volume than the ordinary blast powder, they allow of concentration of

the charge nearer the bottom of the bore-hole. The downward force exerted by explosives is of greatest benefit in mining operations. The substitution of sodium nitrate and barium nitrate for saltpetre was tried more or less successfully, but the chief direction which attempts to produce useful powder substitutes has taken is that of applying the comparatively violent oxidizing properties of potassium chlorate. Among those preparations that are best known are the modifications of the original white or German gunpowder—that is, mixtures of sugar and prussiates of potassium with the chlorate, or preparations consisting of mixtures of tannin, powdered nut-galls, or cream of tartar with the oxidizing agent. Exceedingly crude mixtures of spent tan or sawdust, with saltpetre or other oxidizing salts, together with a little sulphur, have been devised apparently rather with a view to comparative safety than to compete in effects with gunpowder. Picric acid in the form of the potassium and ammonium compounds, mixed with oxidizing salts, has been made the basis of powerful explosive agents, and lately melinite (q.v.), which is a picrate compound, has been adopted by the French. The potassium salt, when intimately mixed with the chlorate, furnishes a product which in susceptibility to detonation and violence of action more nearly resembles nitro-glycerine and gun-cotton than any explosive mixture composed of solid substances, but hitherto it has not been made applicable to practical uses on account of the great readiness with which it is exploded by friction and percussion. M. Designolle made a compound of salt mixed with charcoal, saltpetre, and potassium chlorate from which some favorable results were obtained in France; but much greater satisfaction was had from a mixture of sir Frederick Abel's composed of an equivalent portion of ammonium picrate and saltpetre. Nitro-glycerine, upon which so many of the high explosives depend, is manufactured at various places and by various processes, and at ordinary temperatures is an oily liquid, clear, colorless, or yellowish, refracting light, of sweetish and burning taste, without odor, and of 1.6 specific gravity. It produces serious consequences when taken in the human system, causing vertigo, weakening of sight, stupor, pains in the cardiac region; in larger doses it acts like strychnine, being fatal when more than 10 grains are swallowed. Even mere contact with the skin produces serious symptoms, though workmen get used to it after a time. It does not, when pure, decompose spontaneously at ordinary temperatures, but at high temperatures nitrous acid vapors are disengaged. It may be gradually heated to 100° C., but becomes very sensitive to slight shocks. Putting a light directly to nitro-glycerine does not lead necessarily to detonation. Poured out in a thin layer, the liquid burns away like gunpowder. It is only on being heated in a closed space that its entire mass explodes, when the temperature reaches 257°. Such a heating can be effected by the electric spark. A sudden blow will do it, though it detonates only that portion with which it came in contact. The explosion produced in the part that had been directly exposed to the blow will not communicate itself to the rest of the nitro-glycerine, unless in a solid condition. The detonation of gunpowder, gun-cotton, or fulminate causes nitro-glycerine to explode, whether it is loose or under confinement. *Nitro-gelatine* is the name given to nitro-glycerine solidified by means of gun-cotton collodion. This is more insensible to shock, to friction, and to the pressure or action of water than nitro-glycerine, and a peculiarly powerful detonator must be used with it. Camphor is generally added to render nitro-gelatine insensible to blows, even to projectiles at short range. When thus treated it becomes the *gelatine explosive de guerre*, which is largely employed by various governments for military engineering purposes. *Dynamite* consists of nitro-glycerine absorbed in a porous substance, particularly the infusorial earth called "kieselguhr," which absorbs three or four times its own weight of nitro-glycerine, and possesses the advantage over other absorbents of resisting a greater degree of pressure without parting with any of the nitro-glycerine which it holds. The saturation of the infusorial earth with the nitro-glycerine takes place in the same building in which the liquid is finally washed. In about half an hour the mixture is completed; the mass is now pressed by hand through sieves, and is ready for being filled in cartridges. The cartridges are of cardboard paper or of vegetable parchment; their mode of filling is very simple, and is usually done by hand. *Colonia* and *Hercules* dynamite are mealled gunpowder mixed with about 35 per cent. of nitro-glycerine, and resemble the first nitro-glycerine made in 1863. *Vulcan* is also a dynamite composed of mealled gunpowder holding 43 per cent. of nitro-glycerine. *Seranine* and *Horseley's Powder* are chlorate of potash preparations mixed with nitro-glycerine. The substitution of a chlorate for a nitrate is said not to add to the power, while it adds to the expense of the compound, and also somewhat increases the danger. *Dualine* consists of sawdust, nitrate of potash, and nitro-glycerine. *Lithofractem* is 55 per cent. nitro-glycerine, 21 per cent. kieselguhr, 6 per cent. charcoal, 3 per cent. sulphur and manganese oxide, or either of them, and 15 per cent. barium nitrate and bicarbonate of soda. *Ammonia Powder* consists of 80 parts by weight of nitrate of ammonium, 6 parts of charcoal, and 14 to 20 of nitro-glycerine. *Giant Powder* consists of 40 per cent. of nitro-glycerine added to a mixture of 40 parts nitrate of soda or potash, 6 parts resin, 6 parts sulphur, and 8 parts infusorial earth. Other nitrates and other carbonaceous substances may be substituted for these. *Sebastin* contains a prepared charcoal (made of hazel-wood or elder) which absorbs between five and six times its weight of nitro-glycerine. *Brain's Powder* contains chlorate in the place of nitrate of potash, and, as an absorbent, coal dust, sugar, starch,

or any carbonaceous material. *Rhenish Dynamite* is composed of a solution of 2 to 3 per cent. of naphthaline in nitro-glycerine, 3 parts of chalk, 7 parts of heavy spar, and 20 parts of purified infusorial earth. *Forcite* is a mixture of nitro-glycerine with cellulose, the latter being gelatinized by heating in water under considerable pressure, but nitrated cellulose is also used in admixture with oxidizing salts. *Atlas Powder* is a form of dynamite which has a rather unenviable reputation in England, due to its having been the explosive used in the outrages which were committed in London a few years ago by the so-called dynamiters, and is a composition of nitro-glycerine, wood fibre and nitrate of soda, with 2 or 3 per cent. of carbonate of magnesia. Seven grades of it are made, containing from 20 to 75 per cent. of nitro-glycerine. They are lignum dynamites. *Gelatine dynamite* consists of a thin blasting gelatine mixed with other substances, such as nitrate of potash and wood meal. There are two grades manufactured in England, one containing 80 and the other 60 per cent. of nitro-glycerine. The great advantage of the plastic dynamites, like gelatine dynamite, forcite, etc., is that they can remain in water without being affected or losing their strength. *Glukodine* is a whitish liquid produced by the nitration of a saturated solution of cane sugar in glycerine. Free sugar dissolves in it, and it is soluble in either. Two kinds of glukodine powder are made, white and black. *American Hercules Powder* is of the following composition :

| | No. 1. | No. 2. |
|----------------------------|--------|--------|
| Carbonate of magnesia..... | 20.85 | 10.00 |
| Nitrate of potash..... | 2.10 | 31.00 |
| Chlorate of potash..... | 1.05 | 3.34 |
| White sugar..... | 1.00 | 15.66 |
| Nitro-glycerine..... | 75.00 | 40.00 |

The miners speak very favorably of it, claiming that the fumes are not so bad as from other dynamites. The reason for this is ascribed to the presence of the alkaline absorbent, which, in exploding, gives off explosion gases in which no carbonic oxide is present, and possibly the nitrogen also may enter into combinations which do not affect the organism. *Judson Powder* is made on the principle of rendering the oxidizing salts (nitrates) non-absorbent, and also non-hygroscopic. To the "dope," so prepared 10 per cent. of coarsely ground arthractite is added, and to this mixture 5 or 6 per cent. of nitro-glycerine is added, forming a coating or film over the granules, which renders the dope explosive. *Paleine*, or *Straw Dynamite*, is a mixture of nitro-cellulose, made from straw, with nitro-glycerine ; it is made in Sardinia and Belgium. *Travetle's Dynamite* consists of 75 parts nitro-glycerine, 25 parts gun-cotton and 2 parts charcoal. *Carbo-dynamite* has a base of nitro-glycerine, the absorbent being carbon. *Smolianinoff Explosive* consists of 80 per cent. of nitro-glycerine combined with a certain fluid the nature of which is a secret. *Snyder Explosive* consists of 94 per cent. of nitro-glycerine and 6 per cent. of a compound of collodion, gun-cotton, camphor and ether ; and it is exploded by mere concussion against any hard body. *Von Dahmen's Safety Dynamite* is the discovery of a German chemist, who claims that he has found a means of preventing nitro-glycerine compounds from being affected by a low temperature, as already at 40° F. a congelation of the oil takes place, and of rendering all classes and grades of dynamite non-sensitive to the initial explosion of the detonators, thus dispensing with the troublesome and dangerous operation of thawing. From this enumeration of the many dynamite compounds, it will be noticed that in nearly all of them the nitro-glycerine is mixed with or absorbed by an active base, or dope, and for this reason the dynamites are frequently divided into two groups—dynamites with an inert base, such as kieselguhr, which acts merely as an absorbent for the liquid nitro-glycerine, and dynamites with an active—i.e., a combustible or explosive base. A subdivision of the latter is sometimes made in those having as a base charcoal, gunpowder, or other nitrate or chlorate mixtures, and gun-cotton, or other nitro-compounds.

The first attempts to apply gun-cotton in small arms soon after its discovery, in 1846, were disastrous in their results, and the success which, long afterward, was believed to have been achieved by Von Lentis's indefatigable labors in this direction, was not confirmed by experience. Some of the methods of reducing the rapidity and increasing the action of gun-cotton in small arms consist in the uniform dilution of the gun-cotton either with ordinary cotton, or with the less explosive varieties of the material, and tolerably efficient cartridges for small arms have been furnished for sporting purposes ; but the only direction in which substantial prospect of success has hitherto attended the employment of gun-cotton in arms of precision has been that of converting the very finely divided substance into pellets, or grains, of which the rapidity of explosion has been retarded by their uniform impregnation with small quantities of some perfectly inert material, each particle of gun-cotton being enveloped and separated from those surrounding it by a film of non-explosive substance (such a paraffine, stearine, or caoutchouc). Von Lenk's persevering efforts to improve the manufacture and devise methods of application of gun-cotton, though in themselves not crowned with any permanent success, have contributed considerably to secure an unassailable position for that material as a valuable and safe explosive agent, by leading to its systematic study and the consequent development of its manufacture, and the discovery of its most valuable properties. (See article on GUN-COTTON, ITS MANUFACTURE, ETC.) Sir Frederick Abel

conducted some valuable and interesting experiments illustrative of the force of the detonation of gun-cotton in water, and found that if only a small piece from 0.25 to 1 ounce of compressed gun-cotton be exploded by means of a detonator, in the interior of a shell which is filled up completely with water and closed, the force developed is so suddenly and uniformly transmitted in all directions that the sphere, or cylinder, is broken up into a very much larger number of fragments than is produced by filling the shell with gunpowder or a more violent explosive agent. It has also been proved, by small and large experiments, that the explosion of a substance may be brought about as a phenomenon distinct from that of its detonation, in regard both to the conditions to be fulfilled by its development and the mechanical effects produced by it. The combustion products of gun-cotton *in vacuo* are carbonic oxide, steam and nitrogen; in the open air the same gases, with a nitro-acid and cyanogen. One pound of gun-cotton gives in combustion about 22,165 cub. in. of gas, and produces the effect of from 4 to 6 pounds of gunpowder. The chemical constituents of the gases evolved on combustion are, according to Károlyi (in percentage of volume):

| | In vacuo. | Under high pressure. |
|-----------------------|-----------|----------------------|
| Carbonic oxide..... | 28.55 | 28.95 |
| Carbonic acid..... | 19.11 | 20.82 |
| Fire-damp..... | 11.17 | 7.24 |
| Nitrous oxide..... | 8.83 | |
| Nitrogen..... | 8.56 | 12.67 |
| Steam..... | 21.93 | 25.34 |
| Hydrogen..... | | 3.16 |
| Carbon in excess..... | 1.85 | 1.82 |

If the combustion takes place under high pressure, the nitrous oxide entirely disappears from among the explosion gases, and in its place is formed a greater proportion of carbonic oxide, carbonic acid, steam and nitrogen. Spontaneous combustion begins with the evolution of the gases (for example, gas of a nitro-acid); the gun-cotton gradually diminishes in volume, and the residue contains small portions of a nitrogenous substance, traces of formic acid and acetic acid, also sugar, oxalic acid, and so-called gums. This decomposition appears to take place only when the cotton has not been sufficiently freed from fats, and the gun-cotton has not been completely disacidized. *Pyroxyline* is a term used to designate all nitro-compounds resulting from the action of concentrated nitric acid on cellulose, or wood-fibre—as, for instance, cotton, paper, sawdust, straw, etc. *Schultze's Gunpowder* is practically a nitrated, purified, and pulped wood-fibre formed into grains. *Lannoy's White Powder* is wood, or sawdust, nitrated by treatment with strong nitric acid, and 22 parts of the resulting nitro-cellulose are mixed with 65 parts of sodium nitrate and 13 parts of sulphur. *Uchatin's White Powder* is made of starch of a composition similar to that of cellulose, and can also, by treatment with strong nitric acid, be converted into an explosive nitro-compound called *nitro-starch*. It is too strong and rending in its effects for firearms. Nitro-compounds also result from the action of nitric acid on the various kinds of sugar. Thus there is known a *nitro-raw-sugar*, with an alcoholic solution of which it was proposed to coat ordinary gunpowder, in order to render it impervious to water, and also to increase its explosiveness. A *Nitro-milk-sugar* is also known as *nitro-lachus*. *Nitro-mannite* is obtained from the action of nitro-sulphuric acid on the species of sugar of the mannites, found widely distributed throughout the vegetable kingdom, but principally found in the manna ash. In a pure state it exists in snow-white, needle-shaped crystals, soluble in hot alcohol and in ether. It is an extremely explosive substance, approaching in this respect fulminate of mercury, although not so sensitive to heat or friction. *Johnson's Powders*. In these dinitro-cellulose or lower forms of nitro-cellulose are employed, impregnated with barium or potassium, and incorporated with charcoal or other carbonaceous material. *Punshon's Gun-cotton* was coated, covered, or incorporated with sugar, either raw or refined, in such a manner as to separate or isolate the particles or fibres of the gun-cotton, and thus regulate the rapidity of the combustion. He also added nitre. *Totten's Gunpowder* consists of grains, the kernel of which is pure gun-cotton. It is lighter than ordinary powder, and is four and a half times more effective. *Tontine* consists of finely divided or macerated gun-cotton, compounded with about the same weight of nitrate of baryta. The *white* is used for blasting hard stone, such as quartz, and where the object is to smash up as much as possible locally. The *black* is for softer stone, such as limestone, in quarries, where large blocks of building material are extracted. *Collodion-cotton* is a variety of nitrated cotton which has attained greater importance than gun-cotton itself through its diversity of employment—for instance, in photography, for the preparation of the exposed plate; in blasting, for the production of explosive gelatine from nitro-glycerine; in surgery, for uniting the edges of wounds, and in the manufacture of *Celluloid*. It is really different from gun-cotton in its chemical nature, although the same raw materials serve for the production of both. Gun-cotton is extremely explosive, while collodion-cotton is very slightly so; the former is insoluble in alcoholic ether, while the latter is soluble in that menstruum. Ménard and Flores Domonte were the first to obtain a gun-cotton soluble in alcoholic ether. Béchamp investigated it, and found it to

be dinitro-cellulose. It was soon found that not all gun-cotton was suitable for the manufacture of collodion, and that the most easily explosible was the most insoluble in alcoholic ether. Since the strongest nitric acid produced the strongest gun-cotton, it was concluded and shown that a cotton suitable for collodion manufacture was to be obtained by employing a less concentrated acid. It was also obtained by using potassium nitrate and sulphuric acid instead of the two acids, since in the former case the nitric acid was gradually evolved from the nitrate, and the action in the cotton was less energetic.

One of the great objects had in view by the inventors of high explosives has been their adaptation to war purposes and their use as explosives for shell, torpedoes, and other similar projectiles. Most of the high explosives for this purpose are either gun-cotton or picric acid compounds. It has been generally supposed that picric acid and its compounds were so susceptible to concussion that the mere act of striking against a thin armor-plate would be sufficient to cause shells containing them to explode before they could penetrate. But at the present time it is generally conceded that, with some of these substances, means have been found to delay explosion until after a certain degree of penetration. The principal high explosives at present undergoing experiment are ecrasite, emmensite, extralite, lyddite, melinite, bellite, roborite. *Ecrasite* is said to be a composition of blasting gelatine treated with the sulphate or hydrochlorate of ammonia, or both, and is reported to be as well adapted for use in small arm cartridges as for bursting charges for shells. Extensive private trials have been conducted in Austria, and the effects produced have been stated to resemble those ascribed to melinite. It is said to be exceedingly powerful, and in no way sensitive to mechanical and atmospheric influences. In one experiment an armored tower surmounted by a 6-inch thick armored cupola was used as a target. A shell filled with ecrasite penetrated the cupola and burst inside, destroying the inner parts of the tower and shattering its walls. To show its insensibility to mechanical influences a shell charged with this explosive was fired at a target composed of three 4-inch plates of steel placed close together. The shell perforated the first two plates, and buried itself in the third without exploding. It is said to be perfectly safe to handle, and its effects, as compared with those of dynamite, are stated to be as 10 to 7. The strenuous efforts that are made by the Austro-Hungarian government to guard the secret of its manufacture indicate that it is considered a valuable explosive for military purposes. In Jan., 1888, letters patent were granted to Dr. Stephen H. Emmens, of New York, for a new organic acid discovered by him to which the name of Emmens acid has been given, and the compounds formed with this acid bear the general name of *emmensite*. The acid was at first obtained by dissolving at a gentle heat an excess of commercial picric acid in concentrated fuming nitric acid (50° to 52° C.). This operation was effected without danger, as the mixture is refrigerating. The solution on evaporation deposits rhomboidal prisms of a fine yellow color, which are the new acid. In its simplest form emmensite consists of two ingredients, one of them being a new nitro-derivative of certain hydrocarbons of the aromatic series, which can be prepared by the distillation of coal at a low temperature, whilst the other is a mineral salt. For special purposes other chemical ingredients may be added, but the general character of the compound remains the same in all cases. The ingredients are mixed together by a process which forms one of the principal features of the invention, and the resulting product is a true chemical compound which appears in the form of a solid cake or mass, and may be granulated, by which means it is possible to retard or accelerate the explosive action by increasing or diminishing the size of grain. The grade of emmensite experimented with this year by the government officials was composed of one pound each of the following substances, (1) The combustible (nitrate carbolic acid). (2) Nitrate of soda. (3) Nitrate of ammonia. These were incorporated in the following manner: The combustible was placed in an earthen dish and heated over a fire at a temperature of 250° F., until it became semi-liquid; then 2 and 3 were added in small quantities at a time, the mixture being stirred continually until it finally developed into a yellow paste, which, when taken off the fire and cooled, hardened and assumed a yellow color and crystalline appearance. This substance was then placed in a mortar and pulverized with a pestle, the operation being performed apparently with no thought of any danger from explosion. A spoonful of the substance when lighted burned freely and melted into a dark resinous mass. When mixed with charcoal as a reducing agent and fired from a pistol, it gave a sharp snap for a report, and emitted but a slight whiff of very thin smoke. A charge of 60 pounds, placed under a raft composed of forty ordinary railroad ties securely bolted together and exploded by means of an electric fuse; pieces of the raft were blown to a height of over 200 feet, and not a single tie was left intact. Seven-ounce cartridges of emmensite were separately placed against the top, the sides and bottom of five-eighth-inch iron plates and exploded; in each instance the plate was badly broken. Additional experiments are about being carried out for the benefit of the government with this explosive, which thus far has given better promise than any of the others tried in this country.

Extralite is the invention of Rudolph Sjöberg, of Sweden, and its principal ingredients are an ammoniacal salt (either nitrate or oxalate of ammonia), or hydrocarbon and chlorate of potash. The following are examples of proportions of these ingredients, but these proportions may be varied according as the resultant compound is intended to be used either for blasting or military purposes.

| | | | | | | |
|----------|--------------------|---|----|---|----------|--------------------|
| 50 parts | nitrate of ammonia | } | or | { | 50 parts | oxalate of ammonia |
| 5 " | carbonate of " | | | | 10 " | liquid hydrocarbon |
| 10 " | liquid hydrocarbon | | | | 5 " | solid " |
| 5 " | solid " | | | | 35 " | chlorate of potash |
| 30 " | chlorate of potash | | | | | |

This explosive looks like corn-meal. The following characteristics are ascribed to it: that it cannot be exploded except within rigid enclosures, and then only by the use of a percussion cap; that it cannot be exploded by concussion, and that it is perfectly safe to handle. A percussion primer, when attached to a half pound cartridge and fired in the open air, simply ruptured without exploding the cartridge. Its effects for blasting purposes have been shown to be most powerful.

Lyddite now in use by the English military authorities, is supposed to have been the original melinite, and is believed to be a picric acid compound, composed of chloro-pierin, chloride of picryl, naphthaline, iodo, dinitro, and other phenols. The damage done the *Resistance*, an English man-of-war, against which shells charged with lyddite were fired, was terrific—almost incredible in its extent and thoroughness. It is said to be a very safe compound to handle. *Melinite* has been greatly modified since its first introduction, so that it is now considered a safe explosive in manufacture, handling and stowage, and during the past three years that it has been used but one accident has occurred. Picric acid is its chief constituent, either mixed with some oxidizing substance or simply made into a compact mass with collodion. It is quite generally accepted that melinite is not used alone as an explosive in shells, but has joined with it a substance known as cresilite, which is said to add greatly to its stability and to its safety in handling. In the 6.1 inch gun the high explosive shell is to be 5 calibres long, to weigh 121.2 pounds, and to contain a bursting charge of melinite weighing 22.8 pounds. The common shell now in use with this gun is 3 calibres long, weighs 88.2 pounds, and contains a bursting charge of 3.1 pounds. *Bellite* is a Swedish explosive discovered by M. Carl Lamm, and consists of ammonium nitrate and dinitro-benzol, which, when in a melted condition (the melting point is 80° to 90° C.), are mixed with saltpetre, forming a compound of which each molecule explodes. In its granulated state it has a specific gravity of 1.2 to 1.4, and in this state it may be fully exploded by the aid of a small quantity of fulminating mercury, even if the cover be only a thin sheet of tin; but when pressed into the form of hard cakes it requires a stronger impulse and a stronger cover, which must adhere to the cake. Heated in an open vessel, bellite loses its consistency at 90° C., but does not begin to separate before a temperature of 200° is reached; at that point evaporation begins, and increases with a higher temperature, without, however, explosion occurring. If the heating be sudden, it will burn with a sooty flame something like tar; but if the source of heat be removed, it will cease burning and assume a caramel-like consistency, the ingredients being the same as in the original state, with the exception of a somewhat reduced proportion of saltpetre. Experiments have been made in exploding mines with the compound under water, against a dynamometer, and the average of several such explosions, at a distance of 17 feet, was 10.4 per cent. greater in force than that of gun-cotton under exactly similar circumstances, and at a distance of 12.5 feet the percentage of superiority was increased to 15.2. Various other experiments have served to prove that bellite can withstand blows, fire, friction, and vibration without the slightest risk of explosion, and that it can be stored without danger of spontaneous combustion. *Roburite* belongs to what is known as the Sprengel class of explosives—that is, it is an explosive mixture of two substances neither of which by itself possesses explosive properties. In the case of roburite both compounds are solids, and the resulting mixture has a sandy, granular appearance somewhat resembling the commonest yellow sugar. The inventor, Dr. Carl Roth, claims for roburite the following advantages: (1) That the two components are perfectly harmless and inert separately; (2) that the mixture cannot be exploded by friction, percussion, or the application of flame; (3) that when detonated, roburite produces neither spark nor flame; (4) that it produces very little noxious gas; (5) that it is not subject to deterioration through climatic variations of temperature. It should be kept dry, but if it become damp its strength can be safely restored by the application of heat. Experiment has proved roburite to be much stronger than any picric powder, and in some respects more powerful than dynamite, and this fact, together with its perfect safety, eminently fits it for use as the bursting charge for shells. *Carbo-dynamite* has a base of nitro-glycerine, the absorbent being carbon. It possesses two important advantages over ordinary dynamite: a greater explosive force—90 per cent. of the preparation is pure nitro-glycerine, and the absorbent itself it highly combustible—and there is no exudation of nitro-glycerine even when the dynamite is wet. *Graydonite*, named after its inventor, is another high explosive which is at present undergoing extensive experiments in England. Its composition is not generally known, but its effects are said to be more powerful than the majority of high explosives, while at the same time it is safer to handle. The navy departments of most nations have adopted compressed gun-cotton for torpedo charges and submarine ground mines; whereas the military engineers of the land forces lean toward the use of the plastic nitro-gelatine and its derivatives as demolition charges, owing to their enormous shattering power when bridges, stockades, railway embankments, walls, forts and similar obstacles have to be removed. Such explosives as nitro-gelatine, gelatine-dynamite, and forcite being far more powerful and exerting a greater local action than gun-cotton, should be

able to rival the latter in submarine mining ; but, so far as safety is concerned, wet gun-cotton, no doubt, offers an advantage which nitro-glycerine preparations do not possess. As bursting charges for shells and hollow projectiles, it is thought that modern explosives will doubtless be extensively applied in the near future, and in that shape will form a terribly destructive engine of war. Their efficiency for that purpose has been proved by the dynamite gun (q.v.), the great requisite being to discharge the dynamite shell from the gun without shock. Compressed air is eminently adapted to effect this in a perfect manner, as the pressure admitted to the gun can be regulated to any degree. Therefore, when firing the projectile, a gentle pressure is admitted, at first just sufficient to overcome its friction and inertia ; but, once in motion, the pressure can be rapidly increased up to the full limit, without in any way subjecting the projectile to undue shock. Compressed air also permits the use of a detonator to explode the charge. The Germans have tried a pneumatic dynamite gun of their own, and Maxim has invented a gun of similar type in which a mixture of air and some volatile hydrocarbon is substituted for air alone. The former has successfully undergone experiments, and a cruiser is being built to carry guns made after the pattern experimented with ; the Maxim design has not yet been practically carried out. See SMOKELESS POWDERS ; GUNPOWDER ; GUN-COTTON ; and MÉLINITE. (Authorities consulted, *A Handbook on Modern High Explosives*, by M. Eissler ; *Inaugural Address of Sir Frederick A. Abel, C.B., D.C.L.*, etc., before the British Association ; annual publications of U. S. Navy.

EXPONENT AND EXPONENTIAL. When it was wanted to express the multiplication of unity for any number of successive times by the same number or quantity, e.g., $1 \times 5 \times 5$, or $1 \times a \times a \times a$, it was found a convenient abbreviation to write 1×5^3 and $1 \times a^3$, or simply 5^3 and a^3 ; and the numbers, 2 and 3, indicating how often the operation of multiplication is repeated, were called exponents. But the theory of exponents gradually received extensions not originally contemplated, and has now an exten-

sive notation of its own. Thus, $a^0 = 1$, $a^1 = a$, $a^{-2} = \frac{1}{a^2}$, $a^{\frac{1}{2}} = \sqrt{a}$, $a^{\frac{1}{3}} = \sqrt[3]{a}$, $a^{\frac{2}{3}} = \sqrt[3]{a^2}$, or the cube root of the square of a . Also a^x is the x th power of a , x being any number integral or fractional; and, a continuing the same, x may be so chosen that a^x shall be equal to any given number. In this case, x is called the logarithm of the number represented by a^x . Considered by itself, a^x is an exponential. Generally, any quantity representing a power whose exponent is variable, is an exponential, as a^x , x^x , y^x , etc. Exponential equations are those which involve exponentials, such as $a^x = b$, $x^x = c$.

EXPORTS. See IMPORTS AND EXPORTS.

EX POST FACTO, in law, an act that operates retrogressively ; a law passed after the commission of an act by which such an act may be punished. The constitution of the United States prohibits the passage of such laws, either by congress or by any other legislative body. Chief-Justice Marshall defines an *ex post facto* law to be one which rendered an act punishable in a manner in which it was not punishable when it was committed. Various decisions of the courts make this definition more specific, and hold as *ex post facto* any law which makes criminal an act which, done before its passage, was innocent; any law which makes a crime greater than it was at the time of commission; any law which inflicts punishment greater than was affixed to a crime when committed; any law which changes the rules of evidence as to an offense already committed and to the prejudice of a defendant. The constitutional prohibition of *ex post facto* laws applies to criminal and penal statutes only, and not to those which simply affect property.

EXPOSITION. See EXHIBITION.

EXPOSITION OF THE SACRAMENT, in the Roman Catholic service, is the public exhibition of the holy sacrament, instituted with certain ceremonies, for the veneration of the faithful. There is evidence to warrant the belief that as early as the 14th century the sacrament was thus exposed at least on Corpus Christi, but not until the 16th century did it become customary to expose the host at other times, as on occasions of public distress, when it is said to have been introduced by a Capuchin of Milan, Fr. Joseph, who died in 1556. The practice is still in use, of placing the host within the monstrance above the altar and appointing persons to relieve each other night and day in watching and praying for a period of forty hours. On the second day a mass "for peace" is sung, and it is again placed in the tabernacle after a high mass (that of deposition) has been pronounced. The exposition is not allowed without leave from the bishop or without an apostolic indult. No mass is celebrated at the altar during the exposition ; the bells are not rung at masses said at other altars.

EXPOSURE OF INFANTS. See INFANTICIDE.

EXPRESS, a business which has grown within the past quarter of a century to enormous importance. It was in the spring of 1839 that William F. Harnden advertised to take charge of money and small parcels to transmit between Boston and New York, and from his single carpet-bag has risen a system of inter-communication between places and persons that, for numbers of stations and length of route, is surpassed only by the post-office department. The all-embracing express reached across the ocean as early as 1855, and now this peculiar American institution extends literally to the ends of the earth.

The most valuable articles are sooner intrusted to a responsible express than to government mails, for, in addition to ever-increasing care, there is a system of package insurance which secures the owner in almost any case of loss. The express business is too well known to need any particular description. It is estimated that the American express companies alone cover about 75,000 m. of road; make a travel of 400,000 m. per day; employ over 20,000 men, 4,000 horses, and have from 9,000 to 10,000 offices. A large proportion of the business is the collection of small sums for merchants, the C. O. D. packages implying "collect on delivery" the sum marked on the package as due.

EXTENSION, in logic, is a word put into contrast with another term, **COMPREHENSION**, and the two mutually explain each other. A general notion is said to be extensive according to the extent of its application, or the number of objects included under it. Thus, figure is a term of very great extension, because it contains in its compass many varieties, such as round, square, oblong, polygonal, etc. In like manner, European is more extensive than German, man than European, animal than man, organized being than animal. The highest genera are formed by taking in a wider range of objects. Matter and mind are the most extensive classes that we can form. For, although a higher genus is sometimes spoken of, viz., existence; to call this a class is to generalize beyond real knowledge, which does not begin till we have at least two actual things to contrast with each other. What can be contrasted only with non-existence, non-entity, or nothingness, is not genuine knowledge: no property can be affirmed of it apart from the thing itself. Matter, in its contrast to mind, is a real cognition; and *vice versa*, mind in its contrast to matter. These, then, are the most extensive terms that have any real knowledge attached to them. But this property of E. is gained by dropping more and more of the peculiarities of the included individuals; "organized being," in order to include both plants and animals, must drop from its signification what is peculiar to each, and mean only what is common to both. In short, these very extensive notions have a very narrow signification; it is the less extensive that have most meaning. The meaning of "man," or the number of attributes implied in this generic expression, is large. Everything that goes to a human being—the human form and organization, the mental attributes of reason, speech, etc.—is expressed by this term, which is on that account said to be more **COMPREHENSIVE** than animal or organized being. Thus it may be seen that the greater the E., the less is the comprehension; and the greater the comprehension, the less is the extension.

EXTRACTION OF ROOTS. The roots which have in practice to be most frequently extracted are the *square* and *cube* roots. It is proposed to explain the rule for their extraction as it is given in books of arithmetic. And first of the square root. The square of $a+b$ is $a^2+2ab+b^2$, and we may obtain the rule by observing how $a+b$ may be deduced from it. Arranging the expression according to powers of some letter a , we observe that the square root of the first term is a .

$$\begin{array}{r} a^2 + 2ab + b^2(a+b) \\ \underline{a^2} \\ 2a+b \end{array}$$

Subtract its square from the expression, and the remainder is $2ab+b^2$. Divide $2ab$ by $2a$, and the result is b , the other term in the root. Multiply $2a+b$ by b , and subtract the product from the remainder. If the operation does not terminate, it shows that there is another term in the root. In this case, we may consider the two terms $a+b$ already found as one, and as corresponding to the term a in the preceding operation; and the square of this quantity having been by the preceding process subtracted from the given expression, we may divide the remainder by $2(a+b)$ for the next term in the root, and for a new subtrahend multiply $2(a+b)+$ the new term, by the new term; and the process may be repeated till there is no remainder. The rule for extracting the square root of a number is an adaptation of this algebraical rule. In fact, if the number be expressed in terms of the radix of its scale, it is seen to be a concealed algebraical expression of the order we have been considering. Thus, $N = ar^n + br^{n-1} + \dots + q$. The number 576 in the denary scale may be written $5 \times 10^2 + 7 \times 10 + 6$; and treating it as an algebraical expression, we should find its root to be $2 \times 10 + 4$, or 24. The only part of the arithmetical rule now requiring explanation is the rule of pointing. As every number of one figure is less than 10^1 , its square must be less than 10^2 ; generally, every number of n figures is less than 10^n (which is 1 followed by n ciphers); but also every number of n figures is not less than 10^{n-1} , and therefore its square is not less than 10^{2n-2} —which is the smallest number of $2n-1$ figures. Also, 10^{2n} is the smallest number of $2n+1$ figures. It follows that the square of a number of n figures has either $2n$ or $2n+1$ figures. If, then, we put a point over the units place of a number of which the root is to be extracted, and point every second figure from right to left, the number of points will always equal that of the figures in the root. If the number of figures be even, the number will be divided into groups of two each; if odd, the last group will contain only a single figure.

The rule for the extraction of the cube root of a number is deduced from that for

the extraction of the cube root of an algebraical expression in the same way as in the case of the square root. The cube of $(a + b)$ is

$$\begin{array}{r} a^3 + 3a^2b + 3ab^2 + b^3(a + b) \\ \hline 3a^2) \quad \begin{array}{r} 3a^2b + 3ab^2 + b^3 \\ 3a^2b + 3ab^2 + b^3 \end{array} \end{array}$$

Hence the rule in algebra. Arrange the expression according to descending powers of a , the cube root of the first term a^3 is a , the first term of the root. Subtract its cube from the expression, and bring down the remainder. Divide the first term by $3a^2$, and the quotient is b , the second term of the root. Subtract the quantity $3a^2b + 3ab^2 + b^3$. If there is no remainder, the root is extracted. If there is, proceed as before, regarding $a + b$ as one term, corresponding to a in the first operation. Let, for example, $a + b = a^1$, then $3a^1$ is the new trial divisor. If c be the new term or third figure of the root, then the quantity to be subtracted to get the next remainder is $3a^1c + 3ac^2 + c^3$, and so on till there is no remainder. The rule of pointing in the extraction of the cube root may be proved, as in the case of the square root, by showing that the cube of a number of n figures contains $3n$, $3n - 1$, or $3n - 2$ figures; and, therefore, if we put a point over the units place, and on each third figure, we shall have as many periods as there are figures in the root.

It may be observed that a rule for the extraction of any root of a number may be got from considering how, from the expansion of $a + b$ to the n th power, or $a^n + na^{n-1}b +$, etc., the root $a + b$ is to be obtained. See EVOLUTION AND INVOLUTION.

EXTRACTIVE MATTER is the term applied to certain organic matters resembling humine, found in soils during the decay of vegetable matter, and which are precipitated during the concentration of water solutions.

EXTRACT OF MEAT is obtained by acting upon chopped meat by cold water, and gradually heating, when about one-eighth of the weight of the meat dissolves out, leaving an almost tasteless insoluble fibrine. The extract of meat contains the savory constituents of the meat, and is a light nutritious article of food. See BEEF-TEA and BROTH. It may be concentrated into small bulk, and when desired, may be afterwards treated with water, and being heated, forms an agreeable, light, and nutritive soup. See PRESERVES.

EXTRACTS, in a technical sense, are medicinal preparations of vegetable principles, got either by putting the plants in a solvent or menstruum, and then evaporating the liquid down to about the consistency of honey, or by expressing the juice of the plants and evaporating; this last is properly *inspissated juice*. E., therefore, contain only those vegetable principles that are either held in solution in the juices of the plants themselves, or are soluble in the liquid employed in extracting them, and at the same time are not so volatile as to be lost during evaporation. Now, as many extractive matters are more or less volatile, it makes a great difference whether the operation is conducted at a low or at a high temperature. E. are called *watery* or *alcoholic* according as the menstruum employed is water or spirits. Ether is also used in extracting. Different plants of course afford different E., some being of the nature of bitters, others being used as pigments, tannin, etc. E. are liable to great uncertainty in point of strength and composition, and require to be prepared with great care. Evaporation in vacuo is found to be a great improvement.

EXTRADITION, the delivery up by one state or nation to another of a fugitive from justice. Strictly speaking, extradition is a modern practice, although Hannibal's delivery was stipulated for in a Roman treaty, and more than once Roman citizens were surrendered to a foreign power. These acts, like many others in ancient, mediæval, and early modern times, were confined to those who were considered enemies of the state, or more especially, its head. The national teachings of former centuries made each state feel that it was its duty to injure its neighbor as much as possible. The right to deny the privilege of asylum was a prerogative of the sovereign, and sovereigns frequently used it so as best to secure their mutual personal safety. Thus extradition, or whatever name we give it, was confined to what we should now call political offenses.

It is mainly within the last hundred years that a more Christian international comity has developed. Increased intercourse and the modern means of transportation have greatly facilitated flights from justice, while a sense of common interest has almost destroyed international hatreds. Each decade it has become more evident that the failure of civil justice in one country is likely to result unfavorably to its neighbor. No country has ever willingly received the convicts of another, and it was impossible that nations with liberal ideas should long fail to perceive that there was no great difference between encouraging crime and furnishing an asylum for fugitives from justice. If, then, there was a common national interest in the punishment of criminals, and if offenders against foreign laws were undesirable immigrants, extradition was both an advantage and a duty.

The great writers on international law have not been in harmony in regard to the question as to whether extradition is a matter of perfect obligation. Some of the ablest

have argued in the affirmative, and many more, especially among modern writers, insist that it is a strong moral obligation. As none have denied the importance of extradition, the discussion is really not a practical one. All have admitted that, owing to the great difference between the ideas and penal codes of different nations, it was better for them to give their mutual obligations in this respect definite expression in treaties. Clarke, the leading English writer on extradition, states that its history in England begins with the Ashburton treaty of 1842 with the United States. Excepting the Jay treaty of 1794, which contained an article on extradition limited to twelve years, all the other treaties covering this subject made by the United States are of a subsequent date. The two conventions between the United States and Great Britain, in 1842 and 1890, show what crimes two leading nations of to-day consider extraditable. The former mentioned murder, assault with intent to commit murder, piracy, arson, robbery, forgery, and the utterance of forged papers; the latter added voluntary manslaughter, counterfeiting or altering money, etc., embezzlement, larceny, etc., fraud by a bailee, banker, etc., perjury or subornation of perjury, rape, abduction, childstealing, kidnapping, burglary, etc., piracy by the law of nations, revolt or conspiracy to revolt by two or more persons on board a ship on the high seas, etc., crimes and offenses against the laws of both countries for the suppression of slavery and slave-trading.

The tendency is to enlarge the list of extraditable crimes, but there are many which will not soon, if ever, be included. Such are political crimes; for what one nation considers treason may seem to another to be the height of philanthropy. Offenses against religion and marriage laws are generally regarded as not proper matters for extradition, owing to the fact that hardly any two nations have similar ideas in regard to them. As the custom laws of each nation are considered to be levied against the interests of all others, it would be absurd to expect to add offenses against them to the number of extraditable crimes. The general rule is that an extraditable crime must be one commonly recognized by civilized nations as a *malum in se*, and not a *malum prohibitum*.

The method and prerequisites of extradition may perhaps best be shown by a quotation from the Ashburton treaty. It provides that the two powers shall upon mutual requisitions deliver up to justice all persons charged with the commission of certain crimes "provided that this shall only be done upon such evidence of criminality as, according to the laws of the place where the fugitive or person so charged shall be found, would justify his apprehension and commitment for trial if the crime or offense had there been committed; and the respective judges and other magistrates of the two governments shall have power, jurisdiction, and authority, upon complaint made under oath, to issue a warrant for the apprehension of the fugitive or person so charged, that he may be brought before such judges or other magistrates respectively, to the end that the evidence of such criminality shall be heard and considered; and if, on such hearing, the evidence be deemed sufficient to sustain the charge, it shall be the duty of the examining judge or magistrate to certify the same to the proper executive authority, that a warrant may issue for the surrender of such fugitive." The complaint under oath is commonly made by a consular officer of the state asking for extradition. If all the proceedings are satisfactory, the president of the United States (in our practice) causes the surrender to be made to the agent of the demanding power. The expenses are borne by the party making the requisition.

There are two limitations to the foregoing which are worthy of brief notice. 1. It is an almost universal rule that citizens are not surrendered to foreign powers on extradition requisitions. This is mainly due to two facts. Along certain lines every nation still retains a lingering prejudice that every other nation is an unjust enemy and is incompetent to judge the acts of foreign subjects. Where this prejudice has greatly waned, most nations have passed laws for the punishment of citizens for crimes committed abroad. According to the logic of extradition there seems to be no valid reason for this exception. 2. The question as to whether a person extradited for one offense may be tried for another has frequently arisen. The authorities give many instances of prosecutions for other offenses than those named in the requisitions. In 1870 the British parliament passed a law forbidding the surrender of any fugitive without a positive pledge from the receiving state that he should not be tried for any other offense than that specified in the requisition for extradition, until after he had had an opportunity of returning to her majesty's dominions. Although the United States, during the secretaryship of Hamilton Fish, took serious exception to the application of this law to the famous Winslow case, the principle now receives very general recognition.

From the fact that difficulties in regard to extradition are most satisfactorily anticipated by treaties, it should not be inferred that extradition has not taken place without them. Spain and other countries having no treaty of extradition with Great Britain have surrendered criminals upon her requisition. The rule in the United States is neither to ask nor to grant extradition in the absence of a treaty. The great exception is the Arguelles case, which would probably not have been granted but for the nefarious character of Arguelles' crime, and the peculiar susceptibility at this time of the minds of Lincoln and Seward on the question of slavery. Except as a means of inducing all nations to enter into definite agreements in regard to extradition, there would seem to be no good reason why a fleeing murderer or forger should go unpunished in the absence of a treaty on extradition.

The law of extradition between the different states of the United States is laid down in art. IV. 2 of the constitution, and in a law of congress of Feb. 12, 1793. The former reads, "A person charged in any state with treason, felony, or other crime, who shall flee from justice and be found in another state, shall, on demand of the executive authority of the state from which he fled, be delivered up, to be removed to the state having jurisdiction of the crime." The latter provides for the form in which the demand shall be made, whereupon it shall be the duty of the governor to whom it is addressed to cause the fugitive to be arrested and delivered over to the agent of the other state. The prerequisites of a valid demand are a formal charge that a crime has been committed against the laws of the demanding state, and that the person charged has fled to the state on whose executive the demand is made. Although there have been some striking exceptions, the better opinion is that the governor on whom the demand is made has no option in the matter, although the alleged offense may not be a crime in the state where the fugitive has sought an asylum.

The United States has made treaties with the following named countries :

EXTRALITE. See **EXPLOSIVES OF HIGH POWER.**

EXTRAVAGANTES CONSTITUTIONES, papal constitutions of John XXII. and some of his successors, supplemental to the "Corpus Juris Canonica." They got their name from the fact that they were not arranged in order with the other constitutions, but were "outside wanderers" from the general code.

EXTRAVAGANZA, a musical or dramatic piece of great wildness or absurdity, or characterized by extravagant and fantastic qualities, such as *Hudibras* or *Bombastes Furioso*.

EXTRAVASATION is the escape of any of the fluids of the living body from their proper vessels (*vas*) through a rupture or injury in their walls. Excrementitious matter thus sometimes escapes into the abdomen through a wound or ulceration of the bowels. But the term is oftenest used in speaking of the escape of blood from injured blood-vessels. E. is distinguished from exudation by this, that in the last the vessels remain entire, and the effusion takes place by filtration through their walls; nor does more than a part of the blood so escape, the blood globules being retained, while in E. perfect blood is effused. Many kinds of E. are immediately fatal, such as that of urine or of gall into the abdomen, or of blood from the vessels of the brain in many cases of apoplexy. The dark color resulting from a bruise is owing to extravasated blood.

EXTREME UNCTION, a sacrament of the Roman Catholic church, which, as the other sacraments supply spiritual aid in the various circumstances of life, is believed to impart to the Christian in death grace and strength to encounter the struggle, as well spiritual as bodily, of the dying hour. The right of unction in different forms is common to several of the sacraments; the name "extreme" is given to that of the present sacrament, because it is reserved for the last act of the Christian career. The council of Trent declares this sacrament, although "promulgated" in the well-known passage of St. James v. 14, 15 (which Protestants regard as having more to do with the general belief in the sanative properties of oil), to have been "instituted" by Christ. The fathers

frequently allude to the right of unction, and although many of these allusions certainly refer to the unctions of baptism and confirmation, yet Catholics rely on several passages of Origen, Chrysostom, Cæsarius of Arles, and pope Innocent I., as decisive regarding the unction of the dying, as also upon the fact that in the various separated churches of oriental Christians—Greek, Coptic, Armenian, and Nestorian—the rite is found, although with many ceremonial variations. In the Roman Catholic church, the sacrament is administered by the priest, who, “dipping his thumb in the holy oil, anoints the sick person, in the form of the cross, upon the eyes, ears, nose, mouth, hands, and feet; at each anointing making use of this form of prayer: ‘Through this holy unction, and his most tender mercy, may the Lord pardon thee whatever sins thou hast committed by thy sight. Amen.’ And so of the hearing and the rest, adapting the form to the several senses.”—Challoner's *Catholic Christian Instructed*. E. U. is reputed by Catholics one of the sacraments “of the living;” that is, it ordinarily requires that the recipient should have previously obtained remission of his sins by absolution or by perfect contrition; but it is held to remit, *indirectly*, actual sins not previously remitted, and also (although not infallibly, but according to the merciful designs of Providence) to alleviate, and even to dispel, the pains of bodily disease. The holy oil which forms the “matter” of this sacrament must be blessed by the bishop—a ceremony which is performed with great solemnity once each year by the bishop, attended by a number of priests, on Maundy-Thursday. The oil so blessed is reserved for use during the year. In the Greek church, the sacrament is administered by several priests conjointly. In its most solemn form, seven priests unite in its administration; in ordinary circumstances, it is conferred by two. The Greek form of words also differs, although not substantially, from that of the Latin church. The Greeks call this sacrament “the holy oil,” and sometimes “the oil of prayer.”

EXTREMITY. See SKELETON.

EXUMAS, comprising Great Exuma, Little Exuma, and the Exuma Keys, form part of the group of the Bahama islands. Their inhabitants are employed partly in agriculture, including at one time the growing of cotton, but chiefly in salt-making. Great Exuma is 30 miles long and 3 miles wide, and has one of the best harbors in the Bahamas. It is crossed by the Tropic of Cancer. The population of the group is estimated at 2300.

EXUVIÆ, a term applied to organic remains, now seldom employed, but frequently used by the older geologists.

EYALET, or VILAYET, is the largest and most important of the administrative divisions of the Turkish empire, formerly known as pashalics. These are again divided into *livas* or *sanjaks*, the *livas* into *cazas* or districts, and the *cazas* into *nahiës* or communes, containing villages or hamlets. Each E. or general government, as it may be called, is administered by a pasha, who is governor, and the general name for whom is *call* or viceroy. The governors of the eyalets belong to the dignities of the sword, and are pashas of two tails; and when they are raised to the rank of vizier, as is frequently the case, they become pashas of three tails.

EYAM (pronounced Ee-am) is a small village in a secluded valley of Derbyshire. In the autumn of 1665, the plague was brought here from London in a box of clothing. The rector of the parish, William Mompesson, displayed great courage and devotion in his care for the sick and dying. The plague lingered for over a year, in which time more than 250 out of 350 people died. Another rector of the town survives in history for living in his vestry for years to avoid a breach of promise suit. He lived so until his death, which occurred in 1705. Eyam is noted for barytes mining.

EYAS (formerly *nyas*, *nias*; French, *niais*, stupid; Lat. *nidacem*, fresh from the nest) is a young hawk just taken from the nest to be trained for the chase. See FALCONRY. Eyases were not much thought of by the falconers of the Middle Ages, but are preferred in modern times for the following reasons:—they are easier to obtain, to train, and to keep; they moult better and quicker than passage or wild-caught hawks, and if lost in the field, will frequently find their way home, or will linger near the place where they were liberated. Hawks that have been carefully taught and discreetly work, become exceedingly clever, and very soon learn to regulate their flight by the movements of their master.

EYB, ALBRECHT VON, 1420–1478, was an eminent German ecclesiastic, who became chamberlain to Pope Pius II. In 1472 he published a book of selections from ancient authors, entitled *Margarita Poetica*, which has been frequently reprinted.

EYBAR is a town in the province in Guipuzcoa, Spain, twenty-three miles southwest of St. Sebastian. It is in the midst of picturesque and romantic scenery, and is noted principally for the manufacture of arms. Population, 2396.

EYCK, HUBERT and JAN VAN, two illustrious painters of the old Flemish school. Much discussion has arisen as to the time of the birth of these brothers, and the various dates assigned range from 1350 to 1400. Some maintain that Hubert was born in 1366, and Jan in 1370; while Kugler—in general a good authority on ancient art—states the dates to be 1366 and 1400, making Hubert 34 years older than Jan. Their birthplace

was Maas-Eyck, and they chiefly resided at Bruges and Ghent, and became the founders of the Flemish school of painting. The honor of being the inventors of oil-painting is claimed for them, though sufficient evidence has been adduced to show that it was practiced previously. Before their time, the custom, however, particularly in Italy, was to paint with gums or other substances of an adhesive nature dissolved in water; and if not the inventors, they were at least the first who brought into notice and perfected the mode of mixing colors with oil or some medium of which oil was the chief ingredient; while, for transparent and brilliant coloring and minute finish, their works have never been surpassed. Till the death of Hubert, the brothers generally painted in conjunction; one of their most important works was an altar-piece with folding-doors, representing the Elders adoring the Lamb—a subject taken from the Apocalypse—painted for *Jodocus Vyts*, who presented it to the cathedral of St. Bavon, in Ghent. The two central divisions of this picture are all that now remain in the church at Ghent. Some of the wings are in the gallery at Berlin. The masterpieces of the brothers are for the most part in the cities of Ghent, Bruges, Antwerp, Berlin, Munich, and Paris. In the national gallery, London, there are three pictures of Jan van E., which, though small, well exemplify the high qualities of his works. These are portraits of a Flemish merchant and his wife, standing in the middle of an apartment, with their hands joined—signed and dated 1434: of the portrait of a man in a cloak and fur collar, with a red handkerchief twisted round the head as a turban—painted, according to an inscription on the lower part of the frame, Oct. 21, 1433: and portrait of a man with a dark-red dress, with a green head-covering—signed and dated 10th Oct., 1432. Hubert died in 1436, and Jan in 1440. Compare Waagen, *Ueber Hub. und Jan van Eyck* (Breslau, 1822).

EYCK, KASPAR VAN, a Flemish painter who is known now by his excellent marine views, was born in Antwerp, Belgium, about the middle of the seventeenth century. He died in 1673.

EYCK, MARGARET VAN, a sister of Hubert and Jan (q.v.), is said never to have married because of her devotion to painting. A "Madonna and Child," in the National Gallery in London, has always been considered her work, until recently. The catalogue of 1889 attributes it to an unknown artist of the Early Flemish school. A miniature in the missal of the Duke of Bedford is also attributed to her. She died about 1430.

EYCKENS, PIETER, called the ELDER, painter, was born in Antwerp, Belgium, about 1600. He spent most of his life in his native city painting historical scenes, many of which are in the churches of Antwerp. Among these may be particularly noticed "Elijah Ascending in the Chariot of Fire," and "Saint Catharine Disputing." His paintings are remarkable for their coloring and expression. The date of his death is uncertain. His son, JAN, was an expert painter of fruits and flowers.

EYE, a parliamentary and municipal borough in Suffolk, 20 m. n. of Ipswich. Its streets are rather narrow and irregular. Pop. (1881) of municipal borough, 2,296; of parliamentary borough, 6,293. It sends 1 member to parliament, the parliamentary borough including 11 parishes. Eye, in Anglo-Saxon, means island; the river surrounding the town. Breweries, an iron-foundry, and a large flax manufactory furnish employment.

EYE, JOHANN LUDOLF AUGUST VON, art-historian, was born at Fürstenau, Hanover, May 24, 1825. He was educated at Göttingen. He has written numerous valuable works on both ancient and modern art, and several on philosophical subjects. Among his many works may be noticed particularly *Leben und Wirken Albrecht Dürer's* (1860); *Kunst und Leben der Vorzeit* (1868); *Wesen und Werth des Daseins* (1870); and *Das Reich des Schönen* (1878).

EYE, ANATOMY AND PHYSIOLOGY OF THE. In this article we shall consider: 1. The structure of the human eyeball, and of certain accessory parts or appendages which serve to protect that organ, and are essential to the due performance of its functions. 2. The most striking modifications which this organ presents in some of the lower animals. 3. The special uses of the various parts of the eye considered as an optical instrument; and 4. The action of the retina.

1. The *globe of the eye* is placed in the anterior part of the cavity of the orbit (q. v.) in which it is held in position by its connection with the optic nerve posteriorly, and with the muscles which surround it, and by the eyelids in front. It is further supported behind and on the sides by a quantity of loose fat, which fills up all the interstices of the orbit, and facilitates the various movements of which the eye is capable.

The form of the eyeball is nearly spherical; but on viewing the organ in profile, we see that it is composed of segments of two spheres of different diameters. Of these, the anterior, formed by the transparent cornea, has the smaller diameter, and is therefore the most prominent; and hence the antero-posterior slightly exceeds (by about a line) the transverse diameter. The radius of the posterior or sclerotic segment is about $\frac{1}{8}$ ths, and that of the anterior segment about $\frac{1}{10}$ ths of an inch.

When the eyes are in a state of repose, their antero-posterior axes are parallel; the optic nerves, on the other hand, diverge considerably from their commissure within the cavity of the skull to the point where they enter the globe; consequently, their direction

does not coincide with that of the eye. Each nerve enters the back of the globe at a distance of about $\frac{1}{4}$ th of an in. on the inner side of the antero-posterior axis of the eye.

The eyeball is composed of several investing membranes, and of certain transparent structures, which are inclosed within them, and which, together with the cornea (one of the membranes), act as refractive media of various densities upon the rays of light which enter the eye.

The outermost coat of the eye is the *sclerotic* (from *skleros*, hard). It is a strong, dense, white, fibrous structure, covering about four fifths of the eyeball, and leaving a circular deficiency anteriorly, which is occupied by the cornea. Posteriorly, it is perforated by the optic nerve, and it is there continuous with the sheath which that nerve derives from the dura mater, the fibrous investment of the brain and spinal cord. Near the entrance of the nerve, its thickness is about $\frac{1}{10}$ th of an in.; from this it diminishes to about $\frac{1}{40}$ th; but in front it again becomes thicker, from the tendinous insertions of the straight muscles which blend with it. This coat, by its great strength and comparatively unyielding structure, maintains the inclosed parts in their proper form, and serves to protect them from external injuries.

The *cornea* (so called from its horny appearance) is a transparent structure, filling up the aperture left in the anterior part of the sclerotic. Its circumference is overlaid by the free edge of the sclerotic, which in some parts presents a groove, so as to retain it more firmly; and the connection by continuity of texture between the two structures is so close, that they cannot be separated in the dead body without considerable maceration.

The cornea, in consequence of its greater convexity, projects beyond the line of the sclerotic; the degree of convexity, however, varies in different persons, and at different periods of life. It is thicker than any part of the sclerotic, and so strong as to be able to resist a force capable of rupturing that tunic.

Although beautifully transparent, and appearing to be homogeneous, it is in reality composed of five layers, clearly distinguishable from one another—viz. (proceeding from the front backwards) 1. The conjunctival layer of epithelium. It is in this epithelium that particles of iron, stone, etc., forcibly driven against the eye, usually lodge, and it is a highly sensitive membrane. 2. The anterior elastic lamina forming the anterior boundary of the cornea proper; it is not more than $\frac{1}{3000}$ th of an inch in thickness; and its function seems to be that of maintaining the exact curvature of the front of the cornea. 3. The cornea proper, on which the thickness and strength of the cornea mainly depend. 4. The posterior elastic lamina, which is an extremely thin membrane, in which no structure can be detected. It probably contributes, like the anterior lamina, to the exact maintenance of the curvature of the cornea, so necessary for correct vision. 5. The posterior epithelium of the aqueous humor, which is probably concerned in the secretion of that fluid.

For further details regarding these different layers, we must refer to Todd and Bowman's *Physiological Anatomy*, vol. ii. pp. 17-21.

The *choroid coat* is a dark-colored vascular membrane, which is brought into view on the removal of the sclerotic. Its outer surface, which is nearly black, is loosely connected with the sclerotic by connective tissue, in which are contained certain nerves and vessels—termed the ciliary nerves and vessels—which go to the iris. Its inner surface is soft, villous, and dark-colored. In front, it is attached to the membrane of the vitreous humor by means of the ciliary processes, which consist of about sixty or seventy radiating folds. These are alternately long and short, and each of them is terminated by a small free interior extremity; and they are lodged in corresponding folds in the membrane of the vitreous humor. In other parts, it is loosely connected with the retina. The choroid is composed of minute ramifications of vessels—especially of veins, which, from their whirl-like arrangement, are termed *vasa vorticoso*—of connective tissue, and of pigment cells, which usually approximate to the hexagonal form, and are about $\frac{1}{1000}$ th of an inch in diameter. In albinos, this pigment is absent, and hence their eyes have a pink appearance, which is due to the unconcealed blood in the capillaries of the choroid and iris.

The *iris* may be regarded as a process of the choroid, with which it is continuous, although there are differences of structure in the two membranes. It is a thin flat membranous curtain, hanging vertically in the aqueous humor in front of the lens, and perforated by the pupil for the transmission of light. It divides the space between the cornea and the lens into an anterior (the larger) and a posterior (the smaller) chamber, these two chambers freely communicating through the pupil. The outer and larger border is attached all round to the line of junction of the sclerotic and cornea, while the inner edge forms the boundary of the pupil, which is nearly circular, lies a little to the inner side of the center of the iris, and varies in size according to the action of the muscular fibers of the iris, so as to admit more or less light into the interior of the eyeball; its diameter varying, under these circumstances, from about $\frac{1}{4}$ d to $\frac{1}{8}$ th of an inch. It is muscular in its structure, one set of fibers being arranged circularly round the pupil, and, when necessary, effecting its contraction, while another set lie in a radiating direction from within outwards, and by their action dilate the pupil. These fibers are of the unstriped or involuntary variety. The nerves which are concerned in these movements will be presently noticed.

The varieties of color in the eyes of different individuals, and of different kinds of animals, mainly depend upon the color of the pigment which is deposited in cells in the substance of the iris.

Within the choroid is the *retina*, which, although continuous with the optic nerve—of which it is usually regarded as a cuplike expansion—differs very materially from it in structure. Before noticing the elaborate composition of this part of the eye, which has only been revealed by recent microscopical investigation, we shall briefly mention those points regarding it which can be established by ordinary examination. It is a delicate semi-transparent sheet of nervous matter, lying immediately behind the vitreous humor, and extending from the optic nerve nearly as far as the lens. On examining the concave inner surface of the retina at the back of the eye, we observe, directly in a line with the axis of the globe, a circular yellow spot (*limbus luteus*), of about $\frac{1}{80}$ th of an inch in diameter, called, after its discoverer, the *yellow spot of Sömmerring*. As there has been much discussion regarding the structure and function of this spot, we may observe that Dr. Todd and Mr. Bowman, two of our most eminent English microscopists, after several examinations, regard it as a small mound or projection of the retina towards the vitreous humor, with a minute aperture in the summit. The only mammals in which it exists are man and the monkey. Its use is unknown, but vision is remarkably perfect at this spot—a circumstance which, however, may possibly be accounted for by the fact, that it is singularly free from blood-vessels, which curve round it, and apparently avoid it.

The structure of the retina, as revealed by the microscope, is in the highest degree remarkable. Although its greatest thickness (at the entrance of the optic nerve) is only about $\frac{1}{160}$ th of an inch, and as it extends anteriorly, it soon diminishes to $\frac{1}{320}$ th of an inch, the following layers from without inwards may be distinguished in all parts of it: 1. The layer of rods and cones, frequently termed, from its discoverer, the *membrane of Jacob*; 2. The granular layer; 3. The layer of gray nerve substance; 4. The expansion of the optic nerve; and, 5. The limiting membrane. Details regarding the nature of these various layers are given in Kölliker's *Manual of Human Histology*, and in Todd and Bowman, *op. cit.*

It now remains for us to describe the *transparent media* which occupy the interior of the globe, and through which the rays of light must pass before they can reach the retina, and form on it the images of external objects. We shall consider them in the order in which the rays of light strike them.

Immediately behind the transparent cornea is the *aqueous humor* which fills up the anterior and posterior chambers which lie between the cornea and the lens. As its name implies, it is very nearly pure water, with a mere trace of albumen and chloride of sodium. As no epithelium exists in front of the iris, or on the anterior surface of the lens, it is most probably secreted by the cells on the posterior surface of the cornea.

The *crystalline lens* lies opposite to and behind the pupil, almost close to the iris, and its posterior surface is received into a corresponding depression on the forepart of the vitreous humor. In form, it is a double-convex lens, with surfaces of unequal curvature, the posterior being the most convex. It is inclosed in a transparent capsule, of which the part covering the anterior surface is nearly four times thicker than that at the posterior aspect, in consequence, doubtless, of greater strength being required in front, where there is no support, than behind, where the lens is adherent to the vitreous membrane. The microscopic examination of the substance or body of the lens reveals a structure of wonderful beauty. Its whole mass is composed of extremely minute elongated ribbon-like structures, commonly called the *fibers of the lens*, which are regarded by Kölliker as *thin-walled tubes*, with clear, albuminous contents. These fibers are arranged side by side in lamellæ, of which many hundred exist in every lens, and which are so placed as to give to the anterior and posterior surfaces the appearance of a central star, with meridian lines.

The lens gradually increases in density, and, at the same time, in refracting power, towards the center; by this means the convergence of the central rays is increased, and they are brought to the same focus as the rays passing through the more circumferential portions of the lens. (According to Brewster, the refracting power at the surface is 1.3767, and at the center 1.3990.)

According to Berzelius, the lens contains 58 per cent of water, 36 of albumen, with minute quantities of salts, membrane, etc. In consequence of the albumen, it becomes hard and opaque on boiling, as we familiarly see in the case of the eyes of boiled fish. In the adult, its long diameter ranges from $\frac{1}{8}$ d to $\frac{3}{8}$ ths, and its antero-posterior diameter from $\frac{1}{16}$ th to $\frac{1}{8}$ th of an inch; and it weighs 3 or 4 grains.

The *vitreous humor* lies in the concavity of the retina, and occupies about four fifths of the eye posteriorly. It is inclosed in the hyaloid membrane, which sends numerous processes inwards, so as to divide the cavity into a series of compartments, and thus to equalize the pressure exerted by the inclosed soft gelatinous mass. Between the anterior border of the retina and the border of the lens, we have a series of radiating folds or platings termed the *ciliary processes of the vitreous body*, into which the *ciliary processes of the choroid* dovetail. The vitreous humor contains, according to Berzelius, 98.4 per cent of water, with a trace of albumen and salts, and hence, as might be expected, its refractive index is almost identical with that of water.

The appendages of the eye now claim our notice. The most important of these appendages are the *muscles within the orbit*, the *eyelids*, the *lacrimal apparatus*, and the *conjunctiva*, to which (although less important) we may add the *eyebrows*.

The *muscles* by which the eye is moved are four straight (or *recti*) muscles, and two oblique (the superior and inferior). The former arise from the margin of the optic foramen at the apex of the orbit, and are inserted into the sclerotic near the cornea, above, below, and on either side. The superior oblique arises with the straight muscles; but, after running to the upper edge of the orbit, has its direction changed by a pulley, and proceeds backwards, outwards, and downwards. The inferior oblique arises from the lower part of the orbit, and passes backwards, outwards, and upwards. The action of the straight muscles is sufficiently obvious from their direction: when acting collectively, they fix and retract the eye; and when acting singly, they turn it towards their respective sides. The oblique muscles antagonize the recti, and draw the eye forwards; the superior, acting above, directs the front of the eye downwards and outwards, and the inferior upwards and inwards. By the duly associated action of these muscles, the eye is enabled to move (within definite limits) in every direction.

The *eyelids* are two thin movable folds placed in front of the eye, to shield it from too strong light, and to protect its anterior surface. They are composed of (1) skin; (2) of a thin plate of fibro-cartilage, termed the tarsal cartilage, the inner surface of which is grooved by thirty or forty parallel vertical lines, in which the Meibomian glands are imbedded; and (3) of a layer of mucous membrane, continuous, as we shall presently see, with that which lines the nostrils, and which joins the skin at the margin of the lids, in which the eyelashes (*cilia*) are arranged in two or more rows. The upper lid is much the larger; and to the posterior border of its cartilage a special muscle is attached, termed the *levator palpebræ superioris*, whose object is to elevate the lid, and thus open the eye; while there is another muscle, the *orbicularis palpebrarum*, which surrounds the orbit and eyelids, and by its contraction closes the eye. The Meibomian glands secrete a sebaceous matter, which facilitates the free motion of the lids, and prevents their adhesion. The eyelashes intercept the entrance of foreign particles directed against the eye, and assist in shading that organ from an excess of light.

The *lacrimal apparatus* consists of the lacrimal gland, by which the tears are secreted; two canals, into which the tears are received near the inner angle of the eye; the sac, into which these canals open; and the duct, through which the tears pass from the sac into the nose. The gland is an oblong body, about the size of a small almond, lying in a depression in the upper and outer part of the orbit. The fluid secreted by it reaches the surface of the eye by seven or eight ducts, which open on the conjunctiva at its upper and outer part. The constant motion of the upper eyelid induces a continuous gentle current of tears over the surface, which carry away any foreign particle that may have been deposited on it. The fluid then passes through two small openings, termed the *puncta lacrymalia*, into the canals; whence its further course into the lower portion of the nose is sufficiently obvious. The conjunctiva (or mucous coat) which covers the front of the eyeball, and lines the inner surface of the lids, passes down and lines the canals, sac, and duct; and is thus seen to be continuous with the nasal mucous membrane, of which it may be regarded as an offshoot or digital prolongation. See **MUCOUS MEMBRANES**.

We shall conclude this sketch of the anatomy of the human eye by a brief notice of the *nerves* going to this organ and its appendages.

Into each orbit there enters a nerve of *special sense*—viz., the optic nerve, a nerve of *ordinary sensation*—viz., the ophthalmic branch of the fifth nerve, and certain nerves of *motion* going to the muscular tissues, and regulating the movements of the various parts—viz., the third, fourth, and sixth nerves.

As the optic tracts from which the *optic nerves* originate are noticed in the article **BRAIN**, we shall merely trace these nerves from their *chiasma* or commissure forwards. This commissure results from the junction of the optic tracts of the two sides; and it is especially remarkable for the fact that it presents a partial decussation of the nervous fibers; the central fibers of each tract passing into the nerve of the *opposite* side, and crossing the corresponding fibers of the other tract, while the outermost fibers, which are much fewer in number than the central ones, pass to the optic nerve of the *same* side. In front of the commissure, the nerves enter the optic foramen at the apex of the orbit, receive a sheath or investment from the *dura mater*, acquire increased firmness, and finally terminate in the retina.

The peculiar mode of termination of the optic nerves in the cup-like expansion of the retina, the impairment or loss of vision which follows any morbid affection of them, and the constant relation in size which is observed in comparative anatomy between them and the organs of vision, afford sufficient evidence that they are the proper conductors of visual impressions to the sensorium.

The first or ophthalmic division of the fifth or trifacial nerve sends branches to the skin of the eyelids and to the conjunctiva. That it is the nerve of ordinary sensation of the eye, is sufficiently obvious from the following facts: (1) That in disease of this nerve in the human subject, it is not uncommon to find the eyeball totally insensible to every kind of stimulus (particles of dust, pungent vapors, etc.); and (2) That if the

nerve be divided in the cranium (in one of the lower animals), similar insensibility results.

The most important of the nerves of motion of the eye is the third nerve, or *motor oculi*. It supplies with motor power the elevator of the upper eyelid, and all the muscles of the globe, except the superior oblique and the external straight muscle, and, in addition to this, it sends filaments to the iris and other muscular fibers within the eye. The application of an irritant (in vivisection experiments) to its trunk induces convulsive contraction of the principal muscles of the ball and of the iris; while division of the trunk occasions an external squint, with palsy of the upper eyelid and fixed dilatation of the pupil. The squint is caused by the action of the external straight and the superior oblique muscles, while the other muscles are paralyzed by the operation. The normal motor action of the nerve upon the iris, in causing contraction of the pupil, is excited through the optic nerve, and affords a good illustration of *reflex action*; the stimulus of light falling upon the retina, and, through it, exciting that portion of the brain from which the third nerve takes its origin. This nerve clearly exerts a double influence in relation to vision: (1) it mainly controls the movements of the eyeball and the upper eyelid; and (2) from its connection with the muscular structures in the interior, it regulates the amount of light that can enter the pupil, and probably takes part in the adjusting power of the eye to various distances.

The fourth nerve supplies the superior oblique muscle with motor power, while the sixth nerve similarly regulates the movements of the external straight muscle—the only two muscles in the orbit which are not supplied by the third pair.

Although not entitled to be termed a nerve of the orbit, the facial nerve deserves mention as sending a motor branch to the *orbicularis* muscle, by which the eye is closed.

2. *Comparative Anatomy of the Eye*.—In *mammals*, the structure of the eye is usually almost identical with that of man. The organ is, however, occasionally modified, so as to meet the peculiar wants of the animal. Thus, in the cetacea, and in the amphibious carnivora that catch their prey in the water, the shape of the lens is nearly spherical, as in fishes, and there is a similar thickening of the posterior part of the sclerotic, so as to thrust the retina sufficiently forward to receive the image formed by such a lens. (See the subsequent remarks on the eyes of fishes.) Again, instead of the dark-brown or black pigment which lines the human choroid, a pigment of a brilliant metallic luster is secreted in many of the carnivora, forming the so-called *tapetum lucidum* at the bottom of the eyeball, which seems (according to Bowman) to act as a concave reflector, causing the rays of light to traverse the retina a second time, and thus probably increasing the visual power, particularly where only a feeble light is admitted to the eye. The pupil, moreover, varies in form, being transversely oblong in the ruminants and many other herbivora, and vertically oblong in the smaller genera of cats. These shapes are apparently connected with the positions in which the different animals look for their food. Lastly, in some mammals (for example, the horse), there is a rudimentary third eyelid, corresponding to the *membrana nictitans* of birds.

In *birds*, the eye, though presenting the same general composition as in man, differs from the mammalian eye in several important points. From our knowledge of the habits of birds (especially birds of prey), we should naturally expect that from their rapid movements they should be able readily to alter the focus between the extremes of long and short sighted vision, and the modifications we shall now proceed to notice clearly have this object in view.

By examining a longitudinal section of the eye of the owl, we see (1) that the shape of the organ is not spherical, as in mammals, nor flattened anteriorly, as in fishes and aquatic reptiles, but that the cornea is very prominent, and the antero-posterior diameter lengthened; the consequence of this arrangement being to allow room for a large quantity of aqueous humor, and to increase the distance between the lens and the posterior part of the retina, and thus to produce a greater convergence of the rays of light, by which the animal is enabled to discern near objects, and to see with a faint light. In order to retain this elongated form, we find a series of bony plates, forming a broad zone, extending backwards from the margin of the cornea, and lying embedded in the sclerotic. The edges of the pieces forming this bony zone overlap each other, and are slightly movable, and hence, when they are compressed by the action of the muscles of the ball, there is protrusion of the aqueous humor and of the cornea, adapting the eye for near vision; while relaxation of the muscles induces a corresponding recession of the humor and flattening of the cornea, and fits the eye for distant vision. The focal distance is further regulated by a highly vascular organ called the *marsupium*, or *pecten*, which is lodged in the posterior part of the vitreous humor. It is attached to the optic nerve at the point where it expands into the retina, and seems to be endowed with a power of dilatation and contraction; as it enlarges, from distension of its blood-vessels, it causes the vitreous humor to push the lens forwards, while, as it collapses, the lens falls backwards again towards the retina.

In addition to an upper and lower eyelid, birds have an elastic fold of conjunctiva, which, in a state of repose, lies in the inner angle of the eye, but is movable by two distinct muscles, which draw it over the cornea. It is termed the *membrana nictitans*; it is to a certain degree transparent, for (according to Cuvier) birds sometimes look through it, as, for example, the eagle when looking at the sun. The lachrymal gland

is situated as in mammals, but there is here a second gland, the *glandula Harderi*, which yields a lubricating secretion.

There are no very special peculiarities in the eyes of *reptiles*, and we therefore proceed to notice the most remarkable points presented by the eye in *fishes*. From the comparatively great density of the medium (water) through which the rays of light pass before they impinge upon the transparent structure of the eye of the fish, it is obvious that this organ must act as a very powerful refractive apparatus. The main peculiarity in the eye of the fish is the size, extreme density, and spherical shape of the lens, which give it such an extraordinary magnifying power that it has been employed as a simple microscope. See Brewster's *Treatise on the Microscope*, p. 81. But its focus being shortened in proportion as its power is increased, it is necessary that the retina should be brought near its posterior surface. For this purpose, the eyeball is flattened by diminishing the quantity of vitreous humor, which being of nearly the same density as the external water, exerts no perceptible power in bringing the rays of light towards a focus; and this flattened form is maintained by the existence of two cartilaginous plates in the tissue of the sclerotic, which in some of the larger fishes is actually converted into a bony cup. The aqueous humor having here no refractive power, is barely sufficient to allow the free suspension of the iris. The pupil is very large, so as to take in as much light as possible, but is generally motionless. Their eyes being constantly washed by the water in which they live, no lachrymal apparatus is necessary, nor does any exist; and the same remark applies to the *cetacea* amongst the mammals. We thus see that throughout the sub-kingdom of the *vertebrata* the eye is constructed according to one general scheme, with modifications to suit the mode of life of individual classes.

In all the above cases, the structure of the eye is essentially the same; that is to say, we have certain dioptric media for collecting the divergent rays to their proper focus on the retina, and we have the means of adjusting the eye for different distances. But if we examine the eyes of insects, we find that they are constructed on different principles.

In these animals, we have *simple* and *compound* eyes usually associated in the same individual. The simple eyes resemble in many respects the corresponding organs in higher animals, but the compound eyes are extremely elaborate and complex in their structure. They are two in number, appearing as hemispherical masses on the sides of the head. When examined with the microscope, their surface is seen to be divided into an enormous number of hexagonal facets, which are in fact corneæ. In the ant, there are only 50 of these facets in each eye; in the common house-fly, 4,000; in butterflies, upwards of 17,000; and in some of the beetles more than 25,000. Each cornea is found to belong to a distinct eye, provided with a nervous apparatus, and exhibiting a lens, iris, and pupil. Strauss Durckheim, who has carefully studied these structures in the cockchafer, suggests that, the eyes of insects being fixed, nature has made up for their want of mobility by their number, and by turning them in all directions; so that it might be said that these little animals have a distinct eye for every object.

Compound eyes of similar structure occur in many of the crustaceans.

3. Having now described the anatomical structure of the eye in man and certain of the lower animals, we are able to proceed to the consideration of the uses of the various parts of this organ. Assuming a general knowledge of the ordinary laws of geometrical optics (see *DIOPTRICS*, *LENS*, etc.), we will trace the course of the rays of light proceeding from any luminous body through the different media on which they impinge. If a luminous object, as, for example, a lighted candle, be placed at about the ordinary distance of distinct vision (about 10 in.) from the front of the eye, some rays fall on the sclerotic, and being reflected, take no part in vision; the more central ones fall upon the cornea, and of these some also are reflected, giving to the surface of the eye its beautiful glistening appearance; while others pass through it, are converged by it, and enter the aqueous humor, which probably exerts no perceptible effect on their direction. Those which fall on and pass through the outer or circumferential part of the cornea are stopped by the iris, and are either reflected or absorbed by it; while those which fall upon its more central part pass through the pupil, and are concerned in vision. In consequence of its refractive power, the rays passing through a comparatively large surface of the cornea are converged so as to pass through the relatively small pupil and impinge upon the lens, which, by the convexity of its surface, and by its greater density towards the center, very much increases the convergence of the rays passing through it. They then traverse the vitreous humor, whose principal use appears to be to afford support to the expanded retina, and are brought to a focus upon that tunic, forming there an exact but inverted image of the object.

This inversion of the image may be easily exhibited in the eye of a white rabbit or other albino animal, after removing the muscles, etc., from the back part of the globe. The flame of a candle held before the cornea may be seen inverted at the back of the eye, increasing in size as the candle is brought near, diminishing as it retires, and always moving in a direction opposite to that of the flame.

The adaptation of the eye to distinct vision at every distance beyond that of a few inches, is extremely remarkable, and numerous attempts have been made to explain the mechanism by which its focal length admits of alteration under the influence of the will. One view that has met with much support is, that the focal length is modified by a slight movement of the lens. In the eye of the bird there is a structure termed the

ciliary muscle, which obviously approximates the lens to the cornea when a short field of view is required, and although the corresponding structure is only slightly developed in man and mammals, it is probably sufficiently strong to produce the slight action required; while for the vision of distinct objects the lens is carried back towards the retina by the elasticity of the connecting tissues. It would appear however, from the recent researches of Cramer, Helmholtz, Allen Thomson, and others that the accommodation is effected rather by a change in the *form* than in the *position* of the lens. It has been experimentally proved, that when the eye is turned from a distant to a near object, the antero-posterior diameter of the lens becomes elongated, and the anterior surface becomes more convex, while the opposite changes take place in turning the eye from a near to a distant object. According to Helmholtz, the radius of curvature of the anterior surface of the lens diminishes on turning the eye to a near object from ten to six millimeters (from about 0.4 to 0.24 of an in.), while the most projecting point of the same surface is brought forward about 0.2 of an inch.

Whichever view be adopted, the ciliary muscle takes an active part in the process. According to the observations of Hueck, the focal distance may be changed about three times in a second. The accommodation from a near to a distant object is effected much more rapidly than the converse process.

There are two well-known forms of defective vision in which this power of adaptation is very much limited—viz., short-sightedness or *myopia*, and long-sightedness or *presbyopia*. The limitation, however, is not due to a defect in the muscular apparatus to which we have referred, but to an abnormality either in the curves or in the density of the refracting media. In *short-sightedness* from too great a refractive power from either cause, the rays from objects at the ordinary range of distinct vision are brought too soon to a focus, so as to cross one another, and begin to diverge before they fall on the retina; the eye in this case being able to bring to the proper focus on the retina only those rays which were previously diverging at a large angle from a very near object. The correction for this deficiency is accomplished by interposing between the eye and indistinctly-seen objects a *concave* lens, with a curvature just sufficient to throw the images of external objects at the ordinary distance of distinct vision backwards upon the retina. In *long-sightedness*, on the other hand, there is an abnormal diminution of the refractive power from too flat a cornea, a deficient aqueous humor, or a flattening of the lens, so that the focus is behind the retina. This defect is corrected by *convex* lenses, which increase the convergence of the rays of light. Long-sightedness, as its name *presbyopia* indicates, usually comes on at a comparatively advanced period of life, while short-sightedness is most commonly met with in young persons; but both these rules present occasional exceptions; and the common belief that the latter affection naturally disappears after the middle period of life, is altogether erroneous.

We have already noticed the most essential use of the iris—viz., its power, under the influence of light upon the retina, of modifying the size of the pupil, so as to regulate the amount of light entering the eye. But this is not its only use; one of its offices being to prevent the passage of rays through the circumferential part of the lens, and thus to obviate the indistinctness of vision which would arise from *spherical aberration* (the unequal refraction of the rays passing through the center and near the margin of the lens), in the same manner as the diaphragms employed by the optician. But there are additionally two other means by which this spherical aberration is prevented, which so well illustrate the wondrous mechanism of the eye, that we cannot omit to notice them. They are described by Prof. Wharton Jones as follows:

(1.) "The surfaces of the dioptric parts of the eye are not spherical, but those of the cornea and posterior surface of the lens are hyperbolic, and that of the anterior surface of the lens elliptical—configurations found by theory fitted to prevent spherical aberration. This discovery was made at a time when it was not known but that the dioptric parts of the eye had spherical surfaces.

(2.) "The density of the lens diminishing [as we have already shown] from the center to its periphery, the circumferential rays are less refracted than they would have been by a homogeneous lens with similar surfaces. This elegantly simple contrivance has been hitherto inimitable by human art."—*The Actonian Prize Treatise*, 1851, p. 50.

Chromatic aberration, which is caused by the unequal refrangibility of the primitive rays of which white light is composed, when transmitted through an ordinary lens, whereby colored fringes are produced, is *practically* corrected in the eye, although it is doubtful whether it is *entirely* absent. The provision, however, on which the achromatism depends has not been determined with certainty, probably because we do not yet know the relative refractive and dispersive powers of the cornea and humors of the eye. Sir David Brewster denies that the chromatic aberration receives any correction in the eye, and maintains that it is imperceptible only in consequence of its being extremely slight.

4. We have hitherto been considering the eye as an optical instrument which projects pictures of external objects on the retina; we now come to the action of the nervous tunic, the *retina*, and its adaptation to the physical construction of the eye.

When the retina or the optic nerve is stimulated, we have the sensation of light, whatever may be the nature of the stimulus employed—as, for example, if it be a

blow on the eye in the dark, or irritation of the optic nerve from some morbid condition. The sensation of light, then, consists in a recognition by the mind of a certain condition of these nervous structures, and this condition may be induced by the application of any stimulus; the ordinary stimulus obviously being the rays of light which fall upon the retina. There must, however, be a certain amount of light for the purpose of vision. Every one knows that it is difficult and painful to discern objects in a very faint light; and on the other hand, that on suddenly entering a brilliantly lighted room from the dark, everything appears confused for one or two seconds. There is, however, a gradual adaptation of the retina to different amounts of light. Persons long immured in dark dungeons acquire the power of distinctly seeing surrounding objects; while those who suddenly encounter a strong light, are unable to see distinctly until the shock which the retina has experienced has subsided, and the iris has duly contracted. In protecting the retina from the sudden effects of too strong a light, the iris is assisted by the eyelids, the obicular muscle, and, to a certain extent, by the eyebrows. Moreover, the dark pigment of the choroid coat acts as a permanent guard to the retina, and where it is deficient, as in albinos, an ordinary light becomes painful, and the protective appendages, especially the eyelids, are in constant use.

The persistence, during a certain time, of impressions made on the retina, facilitates the exercise of sight. A momentary impression of moderate intensity continues for a fraction of a second; but if the impression be made for a considerable time, it endures for a longer period after the removal of the object. Thus a burning stick, moved rapidly in a circle before the eyes, gives the appearance of a continuous ribbon of light, because the impression made by it at any one point of its course remains on the retina until it again reaches that point. It is owing to this property that the rapid and involuntary act of winking does not interfere with the continuous vision of surrounding objects; and, to give another illustration of its use, if we did not possess it, the act of reading would be a far more difficult performance than it now is, for we should require to keep the eye fixed on each word for a longer period, otherwise the mind would fail fully to perceive it. Again, in consequence of the retention of sensations by the retina, the image of an object may continue to be seen, especially in certain morbid states of the system, and in twilight, for some seconds after the eyes have been turned away from it, and this physiological phenomenon has probably given origin to many stories of ghosts and visions. Thus, if a person has unconsciously fixed his eyes, especially in the dusk, on a dark post or stump of a tree, he may, on looking towards the gray sky, see projected there a gigantic white image of the object, which may readily be mistaken for a supernatural appearance. These ocular spectra are always of the complementary color to that of the object. Thus, the spectrum left by a red spot is green; by a violet spot, yellow; and by a blue spot, orange. However great may be the velocity of a luminous body, it can always be seen; but if an opaque body move with such rapidity as to pass through a space equal to its own diameter in a less time than that of the duration of the retinal impression, it is altogether invisible; and hence it is, for example, that we cannot see bullets, etc., in the rapid part of their flight.

A small portion of the retina, corresponding to the entrance of the optic nerve, is incapable of exciting the sensation of vision when it receives the image of an object. According to Volkmann, this small invisible spot exactly corresponds in size with the artery lying in the center of the optic nerve. If the "blind spot" had been situated in the axis of the eye, a blank space would always have existed in the center of the field of vision, since the axes of the eyes in vision correspond. But as it is, the blind spots do not correspond when the eyes are directed to the same object; and hence the blank which one eye would present is filled up by the other eye. Mariotte, early in the last century, first described the existence of these blind spots. Any one may satisfy himself of their existence by the following simple experiment. Let two small black circles be made upon a piece of paper, about four or five inches apart, then let the left eye be closed, and the right eye be strongly fixed upon the left-hand circle. If the paper be then moved backwards and forwards, a point will be found at which the right-hand circle is no longer visible, although it reappears when the paper is either brought nearer or removed further. Although no other part of the retina possesses the complete insensibility presented by the blind spot, it is probable that its anterior portions have very little to do with vision. When using only one eye, we direct it towards the object we wish to inspect, in such a way as to throw the image to the back of the globe; and when the eye is thus fixed, objects near the boundary of the field of vision are less distinctly seen than those at its center.

The extent of the field of vision for a single eye, the head being fixed, has been calculated by Dr. Young. He found that the eyeball was capable of a movement of 55 degrees in every direction, so that a single eye may have perfect vision of any point within a range of 110 degrees.

We have not yet referred to the longitudinal range, or greatest distance of human vision; indeed, this range varies so extremely that it is difficult to assign an arbitrary limit to it. Many uncivilized races, as the North American Indians, and the inhabitants of the vast Asiatic steppes, possess powers of sight which would appear almost incredible if they had not been thoroughly and frequently corroborated. Our information is more definite regarding the limits of human vision in regard to the minuteness of the

objects of which it can take cognizance. Ehrenberg has carefully studied this subject; and has arrived at the following results. The side of the smallest square magnitude usually visible to the naked eye—either of white particles on a black ground or conversely—is about $\frac{1}{415}$ th of an inch; and with the greatest condensation of light and effort on the part of the observer, squares with a side as small as $\frac{1}{815}$ th of an inch may be recognized, but without sharpness or certainty. Bodies smaller than these, when observed singly, cannot be discerned by the *naked* eye, but may be seen when placed in a row. Much smaller particles may, however, be distinctly seen, if they powerfully reflect light; thus, gold-dust, which in none of its diameters exceeded $\frac{1}{1125}$ th of an inch, is easily discernible in common daylight. The delicacy of vision is far greater for lines than for minute areas, since opaque threads of $\frac{1}{4500}$ th of an inch may be discerned when held towards the light.

Various topics which the reader might perhaps have expected to find noticed, such, for instance, as “single vision with two eyes,” “the appreciation of solid forms by the sense of vision,” “correct vision with an inverted image on the retina,” etc., which belong fully as much to metaphysics as to physiology, are discussed in the article on VISION. We may also refer those who desire information on these points to Prof. Bain’s treatise on *The Senses and the Intellect*.

EYE, DISEASE OF THE. The diseases of the eye enumerated by the surgeon are very numerous, partly from the variety of the tissues and parts of which it is formed, partly because the exposed situation and transparency of the eye enable the diseases to be seen. Nearly all its parts are liable to inflammation and its consequences. See OPHTHALMIA. The eyelids are liable to various diseases, as growths of several kinds, most of which the surgeon may remove; inflammation, as *blear-eye* (ophthalmia tarsi); to be misdirected inwards or outwards, *entropion* and *ectropion* (q.v.); and the upper eyelid may fall down (ptosis) from palsy of the common motor oculi nerve. The eyelashes may grow in upon the eye (trichiasis), and produce serious results. When plucked out, they grow again; and if they still grow in upon the eye after this palliative treatment has been tried several times, the surgeon has to cut down on their roots, and destroy them. The duct which conveys away the tears to the nose is liable to inflammation and obstruction, causing watery eye. See LACHRYMAL ORGANS. The cornea is liable to opacity in various degrees. The mere *nebula* or cloudy condition, either limited or general, may pass off, and leave the cornea again clear; but the white mark, which is the cicatrix or scar of an ulcer, is permanent, although it may become smaller by the disappearance of the surrounding haze. The pupil may be closed as the result of iritis, or of operations for cataract, and an artificial pupil may be made by either of the three methods—incision, excision, or separation—but the operation is seldom attended with success. For opacities of the crystalline lens, see CATARACT. For an account of diseases of the nervous parts of the eye, see AMAUROSIS. Various affections of vision may arise from peculiar or altered conditions of the refracting humors of the eye—as near-sightedness (myopia), far-sightedness (presbyopia), the appearance of bodies (muscæ) floating in or before the eye; and there may be double vision (diplopia), with two eyes or with one. See VISION. The parts between the eye and its bony orbit may be the seat of inflammation, abscess, or tumor, making the eye protrude. The movements of the eyeballs may be affected from palsy of the motor nerves, or from contraction of the lateral recti muscles, causing inward or outward squinting. See SQUINTING. The eye may lose all feeling, from palsy of the fifth pair of nerves. The whole of the same side of the face, nostril, and mouth, will be in the same condition, and the eye becomes inflamed and disorganized. Substances thrown against the eye may injure it. Quicklime is rapidly destructive to the eye, slaked lime and mortar less so. When one of these, or any other caustic, has got into the eye, sweet oil is the best thing to introduce, until the surgeon arrives to remove them. If it is oil of vitriol (sulphuric acid) that has been the cause of the injury, a weak solution of soda may be used in the first place to neutralize the acid. In gunpowder explosions near the eye, besides the burn, the particles are driven into the surface of it, and will cause permanent black stains over the white of the eye, unless they are carefully removed at the time. When chips of glass, stone, etc., are driven into the interior of the eye, there is little hope of it being saved from destructive inflammation. When only partially sunk into the cornea, as is often the case with sparks of hot iron, or “fires,” as they are called, the rubbing of the projecting part on the eyelid causes great pain, and the surgeon has not much difficulty in removing them. Most commonly these, or other “foreign bodies,” as particles of dust, sand, seeds, flies, etc., merely get into the space between the eyeball and the lids, almost always concealed under the upper, as it is the larger, and sweeps the eye. They cause great pain, from the firmness and sensitiveness of the papillary surface of the lid, soon excite inflammation, and their presence, as the cause, is apt to be overlooked. The lid must be turned round to find them. To do this, pull the front or edge of the lid forwards by the eyelashes, held with the finger and thumb, and at the same time press down the back part of the lid with a small pencil or key. The lid will readily turn round, when the body may be seen about its middle, and may be removed with the corner of a handkerchief. Another plan, which the person himself may try, is to pull forward the upper lid by the eyelashes, and push the lashes of the lower lid up behind

it, when the foreign body may be brushed out. After the bodies are removed, a feeling as if they were still there may remain for some time.

EYEBRIGHT, *Euphrasia*, a genus of plants of the natural order *scrophulariaceæ*, having a tubular calyx, the upper lip of the corolla divided, the lower of three nearly equal lobes, the cells of the anthers spurred at the base, a two-celled capsule and striated seeds. Some of the species are root-parasites. The only British species is the COMMON E. (*E. officinalis*), a little plant of at most 6 or 8 in. in height, with ovate serrated leaves, and white or reddish flowers streaked with purple, appearing singly in the axils of the leaves. It is very abundant in many pastures, and even on high mountains, where—as in very northern regions—it is often to be seen of only an inch in height, gemming the ground abundantly with its bright little flowers. It is a very widely distributed plant, a native of most parts of Europe, the n. of Asia, the Himalaya, etc. It was once in great repute as a cure for ophthalmia, and is still much used in rustic practice for diseases of the eye. A spot on the corolla, something like a pupil, gave it much of its reputation, whilst the fanciful doctrine of *signatures* prevailed in medicine; but it has been found really efficacious in catarrhal inflammations of the eye, and in other catarrhal affections. It is a weak astringent. It is the *euphrasy* of Milton, with which he represents the archangel Michael as *purging the visual nerve* of Adam.

EYE-PIECE, the name given to the microscope by means of which the image of the object formed in the focus of a telescope is observed. See TELESCOPE.

EYLAU, usually called Prussian Eylau, a t. in the government of Königsberg, and 22 m. s. of the town of that name, contains about 3,600 inhabitants, and is celebrated for the battle fought there between Napoleon and the allies—Russians and Prussians—under Bennigsen, Feb. 8, 1807. The French force amounted to about 70,000, and the allies had fewer troops, but were superior in artillery. The battle was opened soon after daylight by a furious attack made by the French left on the Russian right and center, which, however, proved utterly unsuccessful, the attacking corps being all but completely destroyed. The murderous struggle was repeatedly renewed, and the promise of victory alternated now to the one side and now to the other. Night closed upon the whole allied line pressing onward and driving the French before them. Nevertheless, the victory is generally claimed by the latter, chiefly because the allied forces, unable to recruit their strength, were ordered to retreat from the field on the night of the battle, and to retire upon Königsberg. The loss on each side is estimated at about 18,000.

EYRE, EDWARD JOHN, a distinguished explorer and colonial governor, was the son of an English clergyman in Yorkshire, and was b. in 1815. Emigrating to Australia at the age of seventeen, he was prosperous as a squatter, and soon became a magistrate. In 1840 he failed in an attempt to explore the region between south and western Australia—a task he accomplished, in spite of enormous difficulties, in 1841. In 1846 he became lieut.-gov. of New Zealand, and in 1852, of St. Vincent. In 1862 he was appointed governor of Jamaica, where in 1865, negro disturbances broke out. E., resolving on prompt measures, proclaimed martial law; a Mr. Gordon, believed to have had a leading part in the rising, was hurriedly tried by court-martial, and hanged two days after, the sentence having been confirmed by Eyre. A commission sent to inquire into this case, found that Gordon had been condemned on insufficient evidence, and E. was recalled. On his return he was prosecuted for murder by a committee, of whom J. Stuart Mill was the most prominent; Mr. Carlyle and sir R. Murchison promoted the E. defense fund. The charge of murder was dismissed by the magistrates of Market Drayton in 1867. In 1874 he was pensioned and retired from public service.

EYE-STONE, a small calcareous stone found in some shellfish, which was formerly much used, and is still to some extent, to remove foreign substances from the eye. It is put under the lid, and from its lentiform shape is easily moved around by the motion of the eye, and dust or cinders adhering to it are taken out with it.

EYE TEETH, also called *canine* or *cuspidate* teeth, the two teeth in the upper jaw next to the grinders, the fangs of which extend far upwards in the direction of the eye. See also CANINE TEETH.

EZEKIEL (meaning “God will strengthen,” or “strength of God”), one of the Hebrew prophets, was the son of the priest Buzi, and along with Jehoiachin, king of Judah, was carried captive, when still a young man, to Mesopotamia, by order of Nebuchadnezzar, about 598 B.C. He was a member of the Jewish community which settled on the banks of the river Chebar, and first appeared as a prophet about the year 594 B.C. His prophetic career extended over a period of 22 years. The date of his death is not recorded.—The book of Ezekiel consists of three parts: the *first* (chaps. i.–xxiv.), composed before the final conquest of Jerusalem by Nebuchadnezzar, announces the complete overthrow of the kingdom of Judah, on account of its increasing unfaithfulness to God; the *second* (chaps. xxv.–xxxii.) threatens the surrounding nations, which were exulting maliciously over the ruin of Judah, with divine punishment; and the *third* (chaps. xxxiii.–xlvi.) prophesies the future deliverance of the Hebrew nation, and the rebuilding of Jerusalem. This last portion is generally believed to contain several Messianic predic

tions, three of which are considered specially remarkable (chaps. xxxvi.-xxxvii., xxxviii.-xxxix., and xl.-xlviii.); and it is beyond all question that only under a world-wide dispensation like the Christian, can the glorious visions of the prophet receive a historical realization. The book is full of magnificent but artificial symbolism, and of allegories difficult to understand; whence Jerome calls it "a labyrinth of the mysteries of God;" but here and there, as in chapters 1st and 2d, it contains visions that indicate the possession on the part of E. of a most vivid and sublime imagination. E.'s authorship of the book has been questioned. The Talmud says, it was written by the great synagogue, of which E. was not a member; and Ewald, believing that traces of later elaboration are quite obvious, suggests that the collection and combination of the various prophecies into a book may not have been the prophet's own doing. The opinion of most critics, however, is, that a prophet who was so much of a literary artist as E., was more likely to have completed the book himself than to have left such a work to others. The text is far from being in a perfect condition. It is partly corrupted by glosses, has partly been retouched by later hands, and may often be amended by the Septuagint version. The best commentaries on the book of Ezekiel are those of Hävernicks (Erlangen, 1843) and Hitzig (Leip. 1847).

EZEKIEL, BOOK OF (see EZEKIEL), consists of an *introduction* (chapters i.-iii.) reciting the glorious vision in the midst of which Ezekiel received his call to the prophetic office, his commission to Israel, and his encouragements from God; and *three principal parts*.

I. PROPHECIES AGAINST THE PEOPLE OF ISRAEL (chapters iv.-xxiv.), subdivided into 18 sections. 1. The siege of Jerusalem, represented by a picture drawn on a tablet; the prolonged transgressions of the people, by the prophet's continued reclining on his side; and the hardships they should suffer, by the eating of coarse and loathsome bread. 2. Judgments on the city by famine, war, and dispersion abroad, signified by hair and beard cut off, weighed, scattered, and burned. 3. Judgments against idolatry, with a promise that a remnant should be saved. 4. Captivity, inevitable and severe, under the emblem of a chain. 5. Transgressions of Judah, represented by the image of jealousy; and consequent judgments, typified by the scattering of fire, and the departure of the shekinah. 6. The captivity of Zedekiah, represented by the removal of household goods, and bread eaten with trembling. 7. False prophets reprov'd and threatened. 8. Idolatrous elders condemned. 9. The rejection of Jerusalem, represented by the burning of an unfruitful vine. 10. God's compassionate love, against which Israel had sinned, compared to kind care shown to a child cast out at its birth. 11. Judgments on Israel for turning to Egypt for help against Babylon, denounced under the emblem of two great eagles, one representing Nebuchadnezzar, and the other Pharaoh. 12. Judgment denounced on every transgressor for his own sins, contrary to the common proverb implying that children suffer for their fathers' faults. 13. Captivity of the Jewish kings, represented by lions pursued and captured, and of the Jewish people, by a vine scorched, torn up, and planted in the wilderness. 14. God's mercies to Israel, and their continued transgressions reviewed; and, while final forgiveness is promised to the penitent, impending judgments are declared. 15. A consumed forest represents Jerusalem destroyed, and a sharp sword, Nebuchadnezzar cutting down Ammonites and Jews. 16. Recital of sins committed in Jerusalem by all classes of the people, and judgments on them denounced. 17. Idolatries of Samaria and Jerusalem, and their punishment. 18. Dreadful destruction of Jerusalem again proclaimed.

II. PROPHECIES AGAINST VARIOUS NATIONS AROUND JUDEA (chapters xxv.-xxxii.), subdivided into three sections. 1. Against the Ammonites, Moabites, Edomites, and Philistines. 2. Against Tyre (represented, in its beauty, wealth, and renown, as the anointed cherub on the mountain of God) with a promise of returning prosperity to Israel. 3. The destruction of Egypt foretold and illustrated by a recital of Assyria's glory and fall under the emblem of a cedar of Lebanon cut down.

III. PROMISES OF FUTURE DELIVERANCE TO ISRAEL (chapters xxxiii.-xlviii.) subdivided into 6 sections. 1. The prophet is compared to a watchman appointed to give warning of danger, and is exhorted to be faithful. While under the power of the prophetic spirit, being informed that Jerusalem had been taken by Nebuchadnezzar, he foretells the desolation of the land, and reproves the hypocrisy of the captives around him. 2. The rulers, civil and ecclesiastical, condemned as unfaithful shepherds, and a general restoration of the people promised under the guidance of the good shepherd, David the prince. 3. Judgments against Edom again foretold. 4. Promises of restoration renewed to Israel, under the emblems of fruitful mountains, sprinkled water, a new heart, dry bones raised to life, and two sticks united together. 5. Destruction of Gog and Magog, followed by blessings to Israel. 6. Vision of the temple, the returning glory of the Lord, the division of the land, the healing waters from the sanctuary, the portions of the tribes, the city with 12 gates whose name shall be, "The Lord is there."

EZION-GABER, OR EZION-GEGER, the last station of the Israelites before coming to "the wilderness of Zin, which is Kadesh." It was subsequently the station of Solomon's navy; that at which Jehoshaphat's ships were broken. This port, of which no trace remains, is supposed to have been at the modern Ain-el Ghudyan, about 10 m. up the dry bed of the Arabah, and near Elath, or Berenice.

EZRA, a Jewish lawgiver of the 5th c. before Christ. He was descended from a distinguished priestly family, and was resident in Babylon in the reign of Artaxerxes Longimanus. With this monarch he seems to have been in considerable favor, and in the year 478 B.C. obtained permission to return to Jerusalem with a band of his countrymen amounting to 1754. His services to the new colony in regard to their civil and religious condition were very important. He endeavored to reimpose more strictly the law of Moses forbidding marriages with heathen women, and disannulling such ties where they had been formed. He also introduced into Jewish literature the square Chaldee character, instead of the old Hebrew or Samaritan one, which had been customary till then; but the tradition that he rewrote from memory the sacred books burned at the destruction of the temple, deserves no regard; and it is likewise a mere tradition that as president of the so-called great synagogue (an assemblage of Jewish scholars) he arranged and completed the canon of the Old Testament. See **BIBLE**.—The book called by his name, along with the book of Nehemiah, formed, among the Jews, the first and second books of Ezra. It records events which extended over a period of nearly 80 years, and divides itself naturally into two parts. The first six chapters embrace a period of 21 years, and relate the history of the first return from the Babylonish captivity; the rest of the book chronicles the *second* return under Ezra the priest, in the reign of Artaxerxes Longimanus. The book is partly written in Chaldee, and is probably the work of various authors.

EZRA, **BOOK OF** (see **EZRA**), records portions of Jewish history after the captivity. It is divided into two parts, the first of which, comprising six chapters, contains: 1. The decree of Cyrus giving permission to the Jews to return to their own land and rebuild their temple. 2. The record of his restoration of the sacred vessels of silver and gold (numbering in all 5,400) which Nebuchadnezzar had taken from the temple and brought to Babylon. 3. The return of a portion of the people and their commencement of the work. 4. The obstacles placed in their way by men who had taken possession of the land, and, consequently, did not wish the Jews to be re-established in it. 5. When this opposition had continued more than 20 years, Darius Hystaspis, having found the decree of Cyrus, confirmed it and gave the Jews additional privileges and help by which they were enabled to complete their temple and re-establish divine worship. After an interval of nearly 60 years, the second part, comprising four chapters, contains: 1. The decree of Artaxerxes giving Ezra authority to proceed to Jerusalem, with all Jews who wished to accompany him, and re-establish the Jewish state. On this occasion, the king, with his counselors, added large sums of silver and gold to the free-will offerings of the people, and also directed his treasurers in the provinces intervening between Babylon and Jerusalem to furnish the expedition liberally with needed supplies. 2. The arrival of Ezra accompanied by about 1500 chief men and 200 priests and Levites. 3. The reconstruction of the religious and social state of the Jews in accordance with the law of Moses. This reformation included the very difficult work of annulling the marriages which many had made with heathen families of the land. The Jews have always maintained the canonical authority of this book, giving it an equal place with the Pentateuch, and comparing Ezra with Moses. Ezra is justly regarded as the author of the whole book, although in the first part, relating to the actions of others; he drew his materials from various sources; in the second part only he describes events in which he was an eye-witness, a prominent actor, and the chief director.

F

F, **THE** sixth letter in the Latin and English alphabets; corresponding to the *vau* of the Hebrew, and the *digamma* (q.v.) of the old Greek alphabet. See **ALPHABET**.

F and *v* are called *labio-dentals*, from the organs employed in producing them; they belong to the class of consonants called aspirates (q.v.), and bear the same relation to each other that exists between the unaspirated labials *p* and *b*. In Latin, *f* had a peculiar sound, different from that of Greek *φ*, as we learn from Cicero and other Latin writers. What the sound was, we do not exactly know, but it approached to the nature of a strongly breathed *h*, as is indicated by the fact, that in the Sabine dialect it sometimes takes the place of *h*, as Sab. *fircus* = Lat. *hircus* (a he-goat); and the Latins made use both of *faba* and *haba* for "a bean." This affinity is also shown in modern Spanish, where *h* takes the place of the Latin *f*; as Lat. *femina*, Sp. *hembra*; *fl* becomes, in Spanish, *ll*, as Lat. *flamma* = Sp. *llama*. *F*, in English and other Teutonic tongues, corresponds to *p* in Greek and Latin; as Lat. and Gr. *pater* = Eng. *father*; Gr. *pod-*, Lat. *ped-* = Eng. *foot*; Lat. *pisc-* = Eng. *fish*; Gr. *pur* = Eng. *fire*; Lat. *vulp-* = Eng. *wolf*. In some words, *v* takes the place in German of *f* in English; as Ger. *vater* = Eng. *father*; Ger. *vier* = Eng. *four*. In the Aberdeenshire dialect, *f* takes the place of *wh*, as *fat* for *what*; *fup* for *whip*. This seems to be a relic of the Teutonic pronunciation of *w* (= *v*), still to be observed in the Cockney pronunciation of *vill* for *wick*, *ven* for *when*; but why the sharpening of the labial into *f* should be confined to one circumscribed district of Scotland, and to the case of *w* followed by *h*, it is hard to say.

F in Lat. and Greek becomes *b* in Eng.; as Gr. and Lat. *fer* = Eng. *bear*; Lat. *frater* = Eng. *brother*. See Letter B.

More remarkable are the interchanges between *f* and the series *d, th, t*. Lat. *foris* = Gr. *thura*, Eng. *door*; Lat. *fera* = Gr. *ther*, Eng. *deer*; Eng. *red*, Sans. *ruthira*, Gr. *eruthros*, Lat. *rutilus, rufus, ruber*. In Russian, *Feodor, Afanasja* = *Theodor, Athanasia*. In words originally common to both Greek and Latin, the Greek *φ* is represented in Lat. by *f*; as Gr. *φῆμη* = Lat. *fama*. But in spelling Greek words with Latin letters, the Romans, after the time of Cicero, were careful to represent *φ*, not by *f*, which had a somewhat different power, but by *ph*. This mode of spelling words derived from Greek is still adhered to in English, German, and French, although the distinction in sound has long been lost sight of. The distinction began to disappear in the Latin itself in the time of the later Roman emperors, when inscriptions show such spelling as *Afrodite* for *Aphrodite*; and this simplification is followed in modern Italian, Spanish, and Portuguese. *Ph* is sometimes erroneously used in words having no connection with Greek; as Adolphus, for the Teutonic Adolf or Adalolf—i.e., “noble wolf.”

F, in music, is the fourth note of the natural diatonic scale of C, and stands in proportion to C as 4 to 3, and is a perfect fourth above C as fundamental note. F major, as a key, has one flat at its signature—viz., B flat. F minor has four flats the same as A flat major, of which it is the relative minor.

F'S, THE THREE. See IRISH LAND LAWS.

FAAM, or **FAHAM** (*angræcum fragrans*), an orchid, native of India and the Mascarene isles, much prized in the east for the delightful fragrance of its leaves, which is owing to the presence of *coumarin* (q. v.), and resembles that of the tonka bean and of vernal grass. In the isle of Bourbon, an infusion of F. leaves is in great repute as a cure for pulmonary consumption and as a stomachic. In France, it has been successfully employed, under the name of *isle of Bourbon tea*, as an expectorant, anti-spasmodic, and stomachic.

FABACEÆ. See LEGUMINOSÆ.

FABER is the name of two artists, father and son. John F., the elder, was b. in Holland, where he acquired a knowledge of the art of mezzotint-engraving. Subsequently, he went to England, and died at Bristol, May, 1721. His works do not exhibit much talent.—The younger F., also called John, obtained, however, a high reputation as an engraver in mezzotint. His principal works are the portraits of the Kit-cat club, and the beauties of Hampton court, several of which are executed with great freedom, vigor, and beauty. F. lived in London, where he is believed to have died in 1756.

FABER, CECILIA BÖHL VON, 1797-1877; a celebrated novelist of Spain, better known by her masculine pseudonym of FERNAN CABALLERO. She was educated in Spain and Germany, and became an accomplished linguist. In 1813, she returned to Cadiz, and the next year married capt. Planells, whom she accompanied to America, where she passed a number of years of her married life. Not long after the death of her first husband she was married to the marquis de Arco Hermoso, and was a frequent attendant at the Spanish court, where her beauty, vivacity, and wit were much admired. Her second husband died in 1835, and in 1837 she married señor de Arrom, a member of the bar. The union was unfortunate, and it is to the trials and disappointments of her later life that the world is indebted for her literary works. Washington Irving visited her, and encouraged her to pursue Spanish literature, but it was many years later before *The Family of Alvarado*, her first work, was given to the public, nor was it until after her 50th year that she appeared as an author at all, and then under an assumed name. Her works soon became popular, and were translated into French and German, so that within ten years she gained a European reputation. A collected edition in 13 vols. was issued from the Madrid press in 1859, and about the same time she was appointed governess of the royal children. Among the many schemes of her busy life was one for the prevention of cruelty to animals.

FABER, FREDERICK WILLIAM, D.D., 1814-63; b. England; educated at Oxford. He gave up his Calvinist views and became an enthusiastic admirer and follower of John Henry Newman. In 1841, he traveled on the continent, and recorded his observations in *Sights and Thoughts in Foreign Churches and among Foreign Peoples*. In 1845, he was converted to the Roman Catholic faith, and founded a religious community at Birmingham, called Wilfridians, after the name Wilfrid, which he had assumed. This community was ultimately merged in the oratory of St. Philip Neri, of which Newman was the head; and in 1849 a branch was established in London over which Faber presided till his death. He published a number of theological works, and edited the *Oratorian Lives of the Saints*, but it is mainly as a writer of fervent and deeply tender devotional hymns that he is known.

FABER, Rev. GEORGE STANLEY, a learned and voluminous divine of the Anglican church, was the eldest son of the Rev. Thomas Faber, and was b. 25th Oct., 1773. He entered university college, Oxford, in 1789, where he achieved a brilliant academical reputation. Before his 21st year, he was elected fellow and tutor of Lincoln college.

In 1796, he took his degree of M.A.; was Brampton lecturer for 1801, in which capacity he delivered the lectures subsequently published under the title of *Horæ Mosaicæ*; and in 1805 became vicar of Stockton-on-Tees, in the country of Durham. After several changes, he received from bishop Van Mildert, in 1832, the mastership of Sherburn hospital, near the city of Durham, where he died 27th Jan., 1854. F. wrote upwards of forty works, several of which, especially those upon prophecy, have enjoyed a very extensive popularity. All his writings are marked by "strong masculine sense, extensive classical erudition, and a hearty love of hypothesis." The principal are—*The Genius and Object of the Patriarchal, the Levitical, and the Christian Dispensations* (1823, 2 vols.); *The Difficulties of Infidelity* (1824); *The Sacred Calendar of Prophecy* (1828, 3 vols.); *The Primitive Doctrine of Election* (1836), reckoned by some critics the most valuable of all F.'s writings; *The Primitive Doctrine of Justification* (1837); and *Eight Dissertations upon the Prophetic Promises of a Mighty Deliverer* (1845, 2 vols.).

FABER, OR LEFÈVRE, JACOBUS, 1450–1536; surnamed STAPULENSIS; b. Picardy; a pioneer of the Protestant movement in France. He was a graduate of the university of Paris, and professor in the college of cardinal Lemoine. Though his works were very obnoxious to the Roman church he was safe from persecution under the king's protection until the king was taken prisoner at the battle of Pavia. He was then formally condemned, and his works were suppressed; but on the return of Francis all such proceedings were stopped. Among his works were the *Physics, Metaphysics, and Ethics of Aristotle*; and *A Psalter* in five languages. In 1512, he issued a translation into French of the Epistles of St. Paul, and of the whole New Testament in 1523, of the Pentateuch in 1528, and in 1530 of the whole Bible. His work has been the basis of all subsequent French versions. He also published notes and comments constantly exalting the Bible above the church as the rule for human conduct. When the princess Margaret became queen of Navarre, she gave Faber an asylum beyond the reach of his persecutors, where he passed his old age in quiet.

FABIAN GENS. See **FABIUS**.

FABIUS, the name of one of the oldest and most illustrious patrician families of Rome. Three brothers of this name alternately held the office of consul for seven years (485–479 B.C.). In 479, the Fabii, under K. Fabius Vibulanus, migrated to the banks of the Cremera, a small stream that flows into the Tiber a few miles above Rome. Here, two years after, they were decoyed into an ambuscade by the Veientes, with whom they had been at war, and, with the exception of one member, who had remained at Rome, and through whom the race was perpetuated, the entire gens, consisting of 306 men, were put to the sword. The most eminent of the Fabii were Quintus Fabius Rullianus—supposed to have been the first who obtained for himself and his family the surname of *Maximus*—and his descendant, Quintus Fabius Maximus Verrucosus, named Cunctator, the delayer. The former was the most eminent of the Roman generals in the second Samnite war, and was twice dictator, and six times consul. The later, who, in the course of his career, was five times consul, and twice censor, was elected dictator immediately after the defeat of the Romans at Trasimenus. The peculiar line of tactics which he observed in the second Punic war obtained for him the surname by which he is best known in history. Hanging on the heights like a thundercloud, to which Hannibal himself compared him, and avoiding a direct engagement, he tantalized the enemy with his caution, harassed them by marches and countermarches, and cut off their stragglers and foragers, while at the same time his delay allowed Rome to assemble her forces in greater strength. This policy—which has become proverbial as "Fabian policy"—although the wisest in the circumstances, was neither appreciated in the camp nor at home; and shortly after, Marcus Minucius Rufus, master of the horse, was raised to an equal share in the dictatorship, a position, however, which he occupied but for a short time. During his fifth consulship, Fabius recovered Tarentum, which had long been one of Hannibal's important positions. He died in 203 B.C. C. Fabius, surnamed Pictor, executed upon the walls of the temple of Salus—dedicated by the dictator C. Junius Brutus Bubulus in 302—the earliest Roman paintings of which we have any record; and his grandson, Q. Fabius Pictor, was the first writer of a Roman history in prose.

FA'BLE (Lat. *fabula*) is a word of twofold signification. First, it is employed by some writers in a general sense to denote any fictitious narrative, as, for example, the incidents in an epic or dramatic poem. At one time also, when the myths of the Greeks and Romans were thought to be satisfactorily accounted for by regarding them as conscious inventions of the ancient poets and priests, it was customary to speak of them as *fables*, but this application of the term is now abandoned by scholars. See **MYTH**. According to the second and more frequent signification of the word, it denotes a special kind of literary composition, either prose or verse, in which a story of some kind is made the vehicle for conveying a universal truth. It differs from a parable in this respect, that while the latter never transcends in conception the bounds of the probable or the possible, the former always and of necessity does. The story of the "Good Samaritan" imagined by the Savior, is a parable; if it was not true, it might have been, for it contains nothing either improbable or impossible; but when Jotham went up to the top of Mt. Gerizim, and spoke to the men of Shechem about the trees going

forth to anoint a king over them, he made use of the F. proper. The peculiarity, therefore, of the *structure* of the F. consists in the transference to inanimate objects, or, more frequently, to the lower animals, of the qualities of rational beings. By the very novelty and utter impossibility of the representation, the interest of the hearer or reader is excited, and thus its symbolic meaning and moral became transparent to him, at least if the F. is well contrived. The ancient fabulists were simple, clear, and earnest in their representations. They seem to have sprung up in the east. Among the more celebrated are Bidpai (q.v.), or Pilpai, and the Arabian Lokman, who is said to have lived in the time of king David. Among the Greeks, the greatest name is that of Æsop (q.v.), whose fables, at a much later period—the precise time is not exactly known—were versified by a certain Babrius (q.v.). Among the Romans, Phædrus cleverly imitated Æsop, but with considerable modifications, thus giving a certain amount of independent value to his work. It is perhaps worth mentioning here, that the well-known F. of the *Town Mouse and Country Mouse*, told by Horace, is of purely Roman origin, and is probably the only one in existence of which that can be affirmed. Leaving the classical period, and before entering on the dark ages, we encounter the name of Aphythionius, who flourished in the early part of the 4th c., and who wrote indifferent fables in Greek prose; and still later, the name of Flavius Avianus, who composed forty-two, no better, in Latin elegiacs. During the dark ages, the F. in various forms appears to have been cultivated in the monasteries, although nothing meritorious has survived; but in the middle ages, it acquired fresh life and vigor. An edition of the fables current in Germany in the time of the Minnesingers has been published by Bodmer. The oldest known German fabulist is Stricker, who lived about the middle of the 13th c.; but the famous mediæval F. of *Reineke Fuchs*, or the History of Reynard the Fox (q.v.), stretches in some of its numerous primitive forms much further back. In later times, most nations have cultivated the F. with more or less success. We may mention among the English, Gay; among the Germans, Hagedorn and Gellert, and Lessing; among the Italians, Pignotti; among the Russians, Krylov; and above all, among the French, La Fontaine, whose fables are remarkable for their arch and lively humor, their delicate sarcasm, their sagacity, and felicity of expression. Now, however, the F. has gone entirely out of fashion.

FABLIAU, plur. **FABLIAUX** (from the Latin *fabulari*, *fabellare*, to speak or to tell), was the name given in the old French literature to a class of short metrical narratives, intended merely for recitation, and which had for their subject-matter the talk and news of the day in the middle ages. The narrator of such news was called a *fableur* (plur. *fabliers*), in opposition to the *chanteur*, or singer proper, who composed poems not only for recitation, but also for singing. Besides the fabliaux, the department of the *fableur* embraced the *Romans d'aventure* (in short unstrophed couplets), usually called *contes*, whence their author or reciter also bore the name of *conteur*; and the *dits*, or sayings, the special cultivator of which was termed a *diseur*. As the fabliaux were fundamentally distinguished from the more genuine forms of poetry by the every-day character of their subject-matter, so the mode of treatment which their authors adopted was also more anecdotal, epigrammatic, and witty—the wit being richly spiced with scandal. They appear to have maintained a sort of ironical and parodistic antagonism to the idealism of the epics of chivalry. In these fabliaux, the essential character of the French people manifested itself, and that opposition of the real to the ideal, of the understanding to the imagination, which, after the time of Francis I., began to characterize French literature generally. Thus they lashed not only the priesthood and the nobility in their actual degeneracy, but, from the very character of their satire, they engendered a contempt for the religious-chivalric spirit itself, and for all ecclesiastical and knightly notions and ceremonies. The oldest fabliaux are not of French origin; they are a fruit of the crusades, and were brought to France from the east, but they received a national coloring, and soon took root in the west. From them sprung the drama of France. One of the most fecund *fablière* was Rutebeuf, who flourished in the reigns of Louis IX. and Philippe III., whose works were published by Jubinal (2 vols., Paris, 1837). He was a true Parisian, and the prototype of Villon, La Fontaine, and Voltaire. The best collections of fabliaux and *contes* are those of Barbazan (3 vols., Paris, 1756), of Méon (2 vols., Paris, 1823), and of Jubinal (2 vols., Paris, 1839–43). See Bédier, *Les Fabliaux* (1893).

FABRE, FRANÇOIS XAVIER PASCAL, 1766–1837; b. France; a painter, pupil of David. One of Fabre's earliest productions, "Execution of the Children of Zedekiah by order of Nebuchadnezzar," secured for him the great prize of the academy. It was supposed that he was privately married to the duchess of Albany, who at her death made him her sole heir.

FABRETTI, RAFFAELE, a distinguished antiquary and archæologist, was b. at Urbino 1618, and was attracted at an early period to antiquarian studies by the great classical remains of Rome. Under Pope Alexander VII. he became papal treasurer, and subsequently was appointed chancellor to the papal embassy at Madrid. A residence of 13 years in Spain enabled him to explore all the antiquities of the kingdom, and to carry his studies to a point which rendered indispensable his return to Rome, the great parent fount of ancient learning. He was there made judge; and under Innocent XII., became keeper of the papal archives of the castle of St. Angelo, a post which afforded

the widest scope to his favorite pursuits. About this time he wrote his two important works: *De Aquis et Aqueductibus Veteris Romæ* (4 vols., 1680, reprinted with notes and additions in 1788), and *Syntagma de Columnâ Trajanâ* (Rome, 1683). His treatise entitled *Inscriptionum Antiquarum Explicatio* (1699) throws invaluable light on the discoveries made by himself in the catacombs; and his erudite investigations concerning the reliefs known as the Iliac tables, and the grand subterranean canals of the emperor Claudius, are equally full of interest to science. His rare collection of inscriptions, etc., is deposited in the ducal palace of Urbino. F. died in 1700.

FABRIANO, a city of Italy, in the province of Ancona (formerly part of the papal states), is situated at the eastern base of the Apennine range, 28 m. w. of Macerata. It has a cathedral, and several convents, but is chiefly worthy of mention on account of its great paper manufactures, which were established in 1564. The churches and private houses contain many specimens of the school of painting which flourished here. Pop. of commune about 18,200.

FABRIANO, GENTILE DA, an Italian painter, who flourished in the early part of the 15th century. He was born—it is not exactly known when—at Fabriano, and received his first instructions from his father, who appears to have been a man of superior culture, as he taught his son the elements of physics and mathematics. F.'s first teacher in art was, it is supposed, Allegrette de Nuzio. Subsequently, he went to Florence, and studied under Fiesole. Among his earliest works of note is a fresco of the Madonna in the cathedral of Orvieto. In 1423, he painted an "Adoration of the Kings" for the church of the Holy Trinity in Florence. This picture is one of the most admirable belonging to the school of Giotto. To the same period belongs a Madonna with saints (now in the Berlin museum). F. afterwards went to Venice, where he greatly increased his reputation by a picture of the bloody engagement between the fleet of the republic and that of the emperor Babarossa off the heights of Pirano. The Venetian senate was so delighted with the piece, that it conferred on the fortunate artist the dignity of a patrician, and a pension of a ducat *per diem* for life. Unhappily, this work has perished. Pope Martin V. now called F. to Rome, and employed him, along with Vittore Pisanello, in adorning the church of San Giovanni Laterano. As his share of the work, he painted various incidents in the life of John the Baptist, five prophets, and portraits of Pope Martin himself and 10 cardinals. He died, while engaged on this building, some time after 1450. F.'s pictures indicate a cheeful and joyous nature. He had quite a child-like love of splendor and rich ornamentation, but is never extravagant or excessive in his coloring.

FABRICÉ, GEORG FRIEDRICH ALFRED VON, b. 1818; commander of the German army which occupied France in 1871. He was for a long time in the service of Saxony; was secretary of war in 1866, and reorganized the Saxon army after the Prussian plan. He showed admirable administrative ability as well as military genius. He d. in 1891.

FABRICIUS, CAIUS (FABRICIUS) LUSCINUS, a Roman gen., elected consul 282 B.C., and again in 280. He was sent, after the defeat of the Romans by Pyrrhus, to treat for the ransom and exchange of prisoners. Pyrrhus endeavored to bribe him, but all offers were rejected. At a later period, he made peace between the Romans and Pyrrhus.

FABRICIUS, or FABRIZIO, GIROLAMO, commonly named from his birthplace F. AB ACQUAPENDENTE, a celebrated anatomist and surgeon, was b. in 1537, and d. in 1619. He was the son of humble parents who, notwithstanding their poverty, sent him to the university of Padua, where, in addition to the usual instruction in the classics, he studied anatomy and surgery under the celebrated Fallopius with such success, that on the death of the latter in 1562, F. was appointed to fill the vacant professorship. He continued to hold this office for nearly half a century, during which period his high character for eloquence, general erudition, and professional knowledge, attracted students from all parts of the civilized world to the university of Padua. Amongst these students was the Englishman Harvey (q.v.), who attended his prelections in 1598, and who, as will be seen in our notice of his life, derived from F.'s observations on the valves of the veins the first clue to his great discovery. He was a most laborious investigator of nature; and we find him comparing and contrasting the same organ in man, and in several of the lower animals, on a more methodical plan than had been attempted by any of his predecessors. In this way he treated of the eye, the larynx, the ear, the intestinal canal, the development of the fetus, and many other subjects. The improvements which his knowledge of anatomy enabled him to introduce into the practice of surgery were very great; and his *Opera Chirurgica*, which embraced every complaint curable by manual operation, was so highly valued, that it passed through seventeen editions. He was greatly esteemed by his fellow-citizens, for we find that the Venetian republic not only erected for him a spacious anatomical amphitheater, in which his name was inscribed, but at the same time conferred upon him an annual stipend of a thousand crowns, and created him a knight of the order of St. Mark. A few years before his death he retired with an ample fortune, from all professional duties, and died (some believe he was poisoned by his relatives) at the age of 82, in his villa on the banks of the Brenta, which still bears the name of the Montagnuola d'Acquapendente.

We have not space for a list of his numerous anatomical and surgical works. Upwards of a century after his death (in 1723), the celebrated anatomist Albinus collected and published a complete edition of all his anatomical and physiological works.

FABRICIUS, GEORG, 1516-71; b. Saxony; an archæologist. He made a minute examination of the antiquities of Rome, and wrote an elaborate work, so accurate in descriptions that many learned Germans believed it to be from the pen of some ancient writer. In 1553, he was appointed director of the college of Meissen, and held that office till his death.

FABRICIUS, JOANNES ALBERTUS, 1668-1736; b. Leipsic; a learned bibliographer. He stands pre-eminent among scholars for a series of literary catalogues entitled *Bibliotheca Latina*, *Bibliotheca Græca*, and *Bibliotheca Antiquaria*. He studied medicine, and afterwards theology; but most of his life was among books. A list of 128 of his works is given, of which, however, the greater part were merely edited.

FABRICIUS, JOH. CHRISTIAN, a Danish entomologist, b. at Tondern, Jan. 7, 1745, and d. at Kiel in 1808. He studied at Copenhagen, Edinburgh, Leyden, and Freyberg, and finally went to Upsala, to attend the classes of Linnæus. A warm friendship was cemented between master and pupil, and throughout his life F. was zealously employed in developing and applying the ideas and method of the great Swede. In 1775, F. was appointed to the chair of natural history at the university of Kiel, and from that time he devoted himself to the prosecution of his entomological studies, and to the fuller development of a system of classification of insects, based upon the structure of the mouth. Although his system has been found inapplicable to many families of insects, the observations on which it was based have tended materially to the extension of this branch of science. The *Systema Entomologia* (Copenh. 1775), in which F. expounded his views, constituted a new era in the history of entomology, while his *Genera Insectorum* (Kiel, 1776), *Mantissa Insectorum* (Copenh. 1787), and *Entomologia Systematica* (Copenh. 1792), opened hitherto unexplored fields of inquiry to the entomologist. F. was the author of several able treatises on the policy, statistics, and economy of Denmark, which were prepared by him in his capacity of counselor of state and prof. of rural and political economy at Kiel.

FABRONI, ANGELO, an excellent biographical writer, was b. at Marradi, in Tuscany, 7th Feb., 1732, educated at Faenza and Rome, and in 1773, was appointed tutor to the sons of Leopold, grand duke of Tuscany. He died 22d Sept., 1803. His *Vite Italarum Doctrina Excellentium qui Sæculo XVII. et XVIII. floruerunt* (20 vols., Pisa, 1778-1805), is one of the best Italian works of its kind, and contains quite a treasure of information; while his *Laurentii Medicei Vita* (2 vols., Pisa, 1784), and *Vita Magni Cosmi Medicei* (2 vols., Pisa, 1788-89), are reckoned model biographies.

FABULOUS ANIMALS. See **BESTIAIRES, GRIFFIN, UNICORN, BEAST FABLES.**

FABYAN, or FABIAN, ROBERT, b. London, near the middle of the 15th c.; an English chronicler, alderman, and sheriff of London. His *Chronicle* extends from the time when "Brute entered first the ile of Albion" to the year 1485. The chief value of the work is its details of city government and ceremonial.

FAÇADE (Fr.), the exterior front or face of a building. This term, although frequently restricted to classic architecture, may be applied to the front elevation of a building in any style. It is, however, generally used with reference to buildings of some magnitude and pretensions; thus, we speak of the *front* of a house, and the F. of a palace. The back elevation of an important building is called the rear F., in the same way as in England the back of a house is called the "*back front*."

An edifice may have any number of façades when it shows a face or front in each direction. An elevation of the side of a building is called the *lateral façade*. The sides of a court or cortile are also called façades, and are distinguished as n., s., etc., façades.

FACCIOLA'TI, JACOPO, an Italian philologist and critic, was b. at Torreglia, not far from Padua, in 1682. He was educated in the religious seminary at Padua, where he became successively prof. of theology, prof. of philosophy, and superintendent-general of the classes, or rector of the institution. F. directed his attention chiefly to the revival of the study of ancient literature, and with this object, brought out a new edition of the *Lexicon Septem Linguarum*, called, from its original author, the monk Ambrosius of Calepio, the *Calepine Lexicon*. He was assisted in this work by his pupil, Forcellini, to whom is mainly owing the conception of a totally new Latin dictionary; an arduous undertaking, which F. continued till his death in 1769, and which was afterwards completed by Forcellini in 1771. F. and Forcellini, assisted by several others, likewise published a new edition of Nizoli's *Thesaurus Ciceronianus*. F.'s Latin epistles and orations are remarkable for the Ciceronian elegance of their style, and his notices on several philosophical writings of Cicero for their solidity, clearness, and taste.

FACET, a term employed to denote the plane surfaces of crystals, or those artificially cut upon precious stones.

FACIAL ANGLE. See **ANGLE.**

FACIAL NERVE, the seventh cranial nerve in Sömmering's classification, originating in the medulla oblongata, passing through the temporal bone, and issuing from the skull through the stylomastoid foramen. It then branches over the superficial portions of the face, and acts as the muscle of expression. It was formerly classed as a portion of the seventh nerve, the *portio dura*, the other portion being the *portio mollis*, or auditory nerve; according to Sömmering, the 8th pair.

FACIAL NEURALGIA, paroxysmal pains in the head and face, caused by a morbid state of the nervous centre, which may be the result of lack of nutrition, of blood-poisoning, or of hereditary predisposition. It may also be caused by irritation from bad teeth, and by inflammation of the facial nerve.

FACIAL PARALYSIS, a paralysis of the facial nerve on which depends the power to move the muscles of the face. One or both sides of the face may be thus affected, and the attack is quite certain to be attended with a partial or entire loss of the power of articulation.

FAC-SIMILE (Lat. *fac simile*, make like, or an abbreviation of *factum simile*, made like), an exact copy, especially of handwriting, or of printed works, engravings, inscriptions, manuscripts, and the like.

FACTOR, in mathematics. The numbers 6 and 4, multiplied together, *make* 24; hence 6 and 4 are called *factors* of the product 24. Most numbers are products of two or more factors; thus $10=2\times 5$; $12=3\times 4$, or 2×6 , or $2\times 2\times 3$. Every product can be divided by any of its factors without remainder; a factor, therefore, is often called a *divisor*, or measure. 2, 3, 4, 6, 8, 12, are all factors or divisors of 24. Numbers that have no factor or divisor above unity, such as 2, 3, 5, 7, 11, . . . 23, etc., are called *prime* numbers. See NUMBERS, THEORY OF.

FACTOR, a man employed to sell the goods of another; in the United States usually called a commission merchant, because he has his compensation in a commission or percentage upon the goods he sells. He differs from a broker in that he has actual possession of the goods of his principal, and is empowered to deliver them to the purchaser as if they were his own. He generally buys and sells in his own name, so that those dealing with him may not know whether he is owner or factor. Under some limitations for self-protection, he is bound by the instructions of his principal and responsible for damages arising from a violation thereof. In the absence of special instructions, he is bound to use all reasonable care in the management of the property committed to his charge, to employ the usual methods of business, and to have due regard to the welfare and interests of his employer. Otherwise he is not entitled to his commissions; and for injurious negligence or want of proper caution may even be sued by his principal. He cannot delegate his authority without express permission of his principal, except in conformity to general usage or by stress of peculiar circumstances. He cannot sell goods at a sacrifice for the purpose of obtaining his commission and advances. It is generally held in the United States that a factor, who has made advances upon goods, acquires such an interest in them that the principal cannot take them out of his possession by a revocation of his authority. The factor can sell enough of them to reimburse himself, the principal having power over the remainder. The rule in England, however, is different. In many American states, a factor is deemed to be the true owner in the sense that sales made by him to purchasers acting in good faith are valid; even where the sale is made in violation of special instructions title is in certain cases conferred. Sometimes in consideration of an increased commission, he guarantees to the principal payment for the goods which have been sold. In the case he acts under a *del credere* or guaranty commission, and is in general subject to most of the obligations of a surety. A factor whose principal resides in a foreign country stands to purchasers, in most respects, in the relation of an absolute owner, and is therefore under a much greater responsibility. If a factor commits any wrongful act in a sale the principal has a right to recover his goods whenever he can trace them, unless they are in the possession of one who purchased them in good faith. See AGENT; BROKER; COMMISSION DEL CREDERE; COMMISSION MERCHANT.

FACTORIES are establishments where large numbers of persons co-operate in the production of some article of consumption, the principle of the division of labor being in all cases applied. The factory system originated in the manufacture of textile fabrics, to which the remarkable inventions that distinguished the end of the eighteenth century gave such an impulse, by the introduction of machinery and improved methods. By the domestic or home industry that prevailed until superseded by the factories, each weaver performed all the processes of preparing his web or warp within his own dwelling, depending upon the spinner for his supply of yarn, while the latter, not having the means of spinning more than a single thread at a time, was often slow in filling the demand, thereby forcing the weaver to suspend the operations of his loom, and causing a great uncertainty as to the duration of his labor and the amount of his earnings. When, under the stimulus of this need, the spinning machine of Wyatt and Arkwright, the spinning-jenny of Hargreaves, and the improved contrivances of Crompton were successively introduced, one of the obstructions to the development of the cotton industry was removed, and in the small mill, with its few operatives, where this newly invented machinery was employed, we trace the origin of the modern factory system. Upon the completion of the canal system by Brindley, in 1807, and the application of the steam

engine to manufactures, on the breaking out of the American war, the factory movement became more noticeable, and when by the close of the war and the downfall of the slave trade, merchants were forced to seek new channels for the employment of their capital the new system had made extraordinary progress. Its establishment in their country belongs to a somewhat later date. Several laws were passed in England prohibiting the exportation of machinery used in manufactures or models thereof, and in spite of several attempts on the part of the Americans to introduce the English methods, the secrets were tolerably well kept, until the system of water-frame spinning was introduced, and a factory built by Samuel Slater at Pawtucket, Rhode Island, in 1790. Since that time the factory system in the United States, promoted by Whitney's invention of the cotton-gin, in 1792, and by Towell's introduction of the power-loom, with other improvements in his factory at Waltham, in 1814, has maintained an uninterrupted progress and, notwithstanding its later adoption, has surpassed the English system both in the rapidity of its extension and the variety of the industries to which it has been applied. The advantages of its employment having been seen in the progress of the textile manufactures, it was applied to the manufacture of boots and shoes, of watches, musical instruments, agricultural implements, clothing, metallic goods generally, fire-arms, carriages and wagons, woolen goods, and even in the killing of pigs, until it is now estimated that fully four-fifths of the people employed in the mechanical industries of this country are working under the factory system.
